New antimicrobials – before and after entering clinical development

P532 Antimicrobial activity of telavancin against *Enterococcus faecalis*, *E. faecium* and *E. avium*: results from a European surveillance programme (2007)

T. Fritsche, H. Sader, R. Jones (North Liberty, US)

Objectives: To evaluate the potency of telavancin (TLV) against enterococcal isolates (*Enterococcus faecalis* [EF], *E. faecium* [EFM] and *E. avium* [EAV]) collected as part of a European surveillance protocol for 2007. TLV is an investigational, intravenous, semi-synthetic, rapidly bactericidal lipoglycopeptide that is broadly active against both aerobic and anaerobic Gram-positive bacteria. The agent has been evaluated in two Phase 3 complicated skin and skin structure infection clinical trials.
Methods: Non-duplicate clinical isolates (919 total; see Table) of EF (579), EFM (318) and EAV (12) were submitted from 26 medical centres in Europe participating in TLV surveillance. Identifications were confirmed by the central monitor and all isolates were susceptibility tested using CLSI broth microdilution methods.
Results: Among the comparators, TLV was the most potent agent tested against *Enterococcus* spp. (EF and EFM; MIC50 values, 0.25 and 0.06 mg/L, respectively; see Table) compared with vancomycin (VAN; 1 and 1 mg/L), daptomycin (1 and 2 mg/L), levofloxacin (1 and >4 mg/L), and linezolid (1 and 1 mg/L). TLV was 4-fold more active (MIC50) than VAN against EF and 16-fold more active against EFM (only 15.4% of EFM had TLV MIC values of >1 mg/L compared with 29.6% having VAN MIC values >4 mg/L). Overall, 9.7% of tested enterococci were VAN-resistant, including 1.0% of EF and 25.8% of EFM; TLV remained ⩾16-fold more potent (MIC50) than VAN against these resistant EFM strains. Among the comparators, only daptomycin and linezolid were uniformly active against all enterococci (>99% susceptible), followed by teicoplanin (92.4%) and VAN (88.9%). All but one strain of EAV were inhibited by ⩽0.06 mg/L of TLV.

Table. Antimicrobial activity of telavancin against year 2007 enterococcal isolates

Organism (N)	MIC (mg/L)		Cumulative % inhibited at MIC (mg/L)				
	50%	90%	⩽0.06	0.12	0.25	0.5	1
EF (579)	0.25	0.5	1	22	84	99	99
VAN-susceptible (573)	0.25	0.5	1	23	84	100	–
VAN-resistant (6)	>2	>2	0	0	0	0	0
EFM (318)	0.06	2	66	79	80	80	85
VAN-susceptible (224)	0.06	0.12	82	99	100	–	–
VAN-resistant (82)	2	>2	18	21	21	22	40
EAV (12)	0.06	0.06	92	92	92	92	100

EAV, *Enterococcus avium*; EF, *E. faecalis*; EFM, *E. faecium*; VAN, vancomycin.

Conclusions: Based on MIC50 potencies, TLV was the most active agent tested against European (2007) *Enterococcus* spp. isolates, and inhibited 94.0% of strains at ⩽1 mg/L, whereas only 88.9% were inhibited by ⩽ 4 mg/L of VAN (current breakpoint). Continued monitoring for resistance emergence in enterococci and other Gram-positive pathogens will be critical in assessing the long-term efficacy of this promising agent.

P533 Activity of telavancin tested against *viridans* group and beta-haemolytic streptococci, and multidrug-resistant *Streptococcus pneumoniae*

T. Fritsche, G. Moet, H. Sader, R. Jones (North Liberty, US)

Objectives: To evaluate the activity of telavancin (TLV) tested against *viridans* group streptococci (VGS, five species), beta-haemolytic streptococci (BHS) and *Streptococcus pneumoniae* (SPN), including multidrug-resistant strains. TLV is a novel, rapidly bactericidal lipoglycopeptide active against Gram-positive pathogens, including resistant subsets, and has been evaluated in complicated skin and skin structure infection clinical trials.
Methods: The activity of TLV was compared with those of other antimicrobial classes using reference broth microdilution (CLSI, M7-A7; Mueller-Hinton broth supplemented with 2–5% lysed horse blood) methods tested against 1005 streptococci (100 each of five VGS species; 100 each of Lancefield Groups B, C and G BHS; and 205 SPN, including multidrug-resistant patterns [>3 classes]) recovered from global surveillance programmes.
Results: Among tested VGS, 99.8% had TLV MICs of ⩽0.06 mg/L. All MIC50 and MIC90 values for *S. anginosus*, *S. constellatus*, *S. mitis* and *S. oralis* were 0.03 mg/L; *S. intermedius* showed an elevated MIC90 (0.06 mg/L) and the highest TLV MIC (0.25 mg/L). Serogroups B, C and G BHS had the same modal TLV MIC (0.03 mg/L), but MIC90 results varied from 0.03 mg/L for Group C BHS to 0.06 mg/L for Groups B and G BHS. All BHS were inhibited by ⩽0.12 mg/L. Against SPN, TLV had a pronounced modal MIC at 0.015 mg/L (also MIC50 and MIC90) and 99.5% of results were either 0.008 or 0.015 mg/L (highest MIC). No difference in the TLV MIC90 (0.015 mg/L) was observed, but the MIC50 was slightly lower (0.008 mg/L) for two resistance phenotypes (penicillin-nonsusceptible [30 strains] and erythromycin-resistant [10 strains]). TLV MIC results did not correlate with mechanisms of resistance found for β-lactams, macrolides, tetracyclines, fluoroquinolones and trimethoprim/sulfamethoxazole. Overall, >99% of TLV MIC results occurred within three dilution steps (0.015–0.06 mg/L) for the tested streptococci.
Conclusions: TLV was found to be highly potent against prevalent VGS, BHS and SPN. All isolates were inhibited by ⩽0.06 mg/L TLV, with two exceptions (0.2%): one group G BHS at 0.12 mg/L and one *S. intermedius* at 0.25 mg/L. These results demonstrate that TLV may be an excellent therapeutic candidate for serious infections caused by these pathogenic organisms.

P534 Antimicrobial activity of telavancin and comparator agents tested against recently isolated (2007) European *Staphylococcus aureus* and coagulase-negative staphylococci

T. Fritsche, D. Biedenbach, H. Sader, R. Jones (North Liberty, US)

Objectives: Telavancin (TLV) is an investigational, novel, rapidly bactericidal lipoglycopeptide that is broadly active against Gram-positive pathogens, and has completed complicated skin and skin structure infection clinical trials. Given concerns over the rapid emergence of resistance among staphylococci, including community-acquired strains, we compared the potency of TLV versus other antimicrobials against contemporary oxacillin-susceptible (OX-S) and OX-resistant (OX-R) *Staphylococcus aureus* (SA) and coagulase-negative staphylococci (CoNS) collected as part of a European antimicrobial resistance surveillance programme.
Methods: Consecutive, non-duplicate patient isolates (n = 2834) were submitted from 26 medical centres in Europe (10 countries), Turkey and

Israel during 2007 (2202 SA [OX-R, 29.3%], 632 CoNS [OX-R, 76.1%]) and susceptibility tested using CLSI (M7-A7) broth microdilution methods.

Results: Compared with OX-S SA, TLV MIC90 values varied by one dilution in OX-R SA (0.12 versus 0.25 mg/L, respectively; see Table), but was unchanged for OX-R CoNS (0.25 mg/L); all isolates were inhibited by ⩽0.5 mg/L. TLV was 2-, 4- and 8-fold more potent (MIC90) than daptomycin, vancomycin and linezolid, respectively, when testing SA, and 2-, 8- and 4-fold more potent, respectively, when testing CoNS. Among CoNS, TLV was most active against *S. lugdunensis* (MIC50, 0.06 mg/L) and least active against *S. warneri* (MIC50, 0.25 mg/L; 10 isolates each); MIC50 values for other species (*S. capitis* [20 isolates], *S. epidermidis* [316 isolates], *S. haemolyticus* [34 isolates], and *S. hominis* [59 isolates]) were all 0.12 mg/L. High levels of R to other agents were observed among OX-R SA and CoNS with respective R rates (%) as follows: erythromycin (69.8/68.0), clindamycin (30.0/29.7), gentamicin (19.7/37.9), levofloxacin (90.7/65.7), tetracycline (11.6/18.3) and trimethoprim/sulfamethoxazole (1.9/45.3).

Organism (N)	MIC (mg L)							
	TLV		VAN		LEV		LZD	
	50%	90%	50%	90%	50%	90%	50%	90%
OX-S SA (1556)	0.12	0.12	1	1	⩽0.5	⩽0.5	1	2
OX-R SA (646)	0.12	0.25	1	1	>4	>4	1	2
OX-S CoNS (151)	0.12	0.25	1	2	⩽0.5	⩽0.5	0.5	1
OX-R CoNS (481)	0.12	0.25	2	2	4	>4	1	1

LEV, levofloxacin; LZD, linezolid; TLV, telavancin; VAN, vancomycin.

Conclusions: TLV displayed higher potency than the other agents tested against SA and CoNS (MIC50 and MIC90 values for both, 0.12 and 0.25 mg/L), and inhibited all isolates at ⩽0.5 mg/L. TLV exhibited similar potency for OX-S and -R strains. The continued and rapid emergence of resistant staphylococci, including community-associated OX-R SA, necessitates the timely introduction of new therapeutic agents and longitudinal surveillance to assist in control efforts.

P535 Activity of telavancin against isolates from recently completed Phase 3 studies of complicated skin and skin structure infections

K.M. Krause, S.L. Barriere, M.M. Kitt, B.M. Benton (South San Francisco, US)

Objective: Telavancin (TLV) is a novel, bactericidal lipoglycopeptide with a broad and potent Gram-positive spectrum of activity that includes meticillin-resistant *Staphylococcus aureus* (MRSA). TLV possesses a unique, multifunctional mechanism of action that includes inhibition of cell wall biosynthesis and disruption of bacterial membrane function. The efficacy and safety of TLV have been studied in patients with complicated skin and skin structure infections (cSSSIs) in two methodologically-identical, worldwide, Phase 3 studies (ATLAS 1 and ATLAS 2). Here, we report the susceptibility testing results for TLV and comparators against the Gram-positive isolates collected in these studies.

Methods: A total of 1506 baseline Gram-positive isolates were obtained from 1867 cSSSI patients enrolled in the ATLAS studies throughout North America, Europe, South Africa, South America and Asia during 2005 and 2006. All isolates were identified and susceptibility tests were performed at a central laboratory. MIC values were determined by the CLSI broth microdilution method, using frozen reference MIC panels.

Results: MIC50, MIC90 and ranges for TLV against staphylococci, streptococci and enterococci are shown in the table. Based on MIC90 comparisons, TLV was 2–4-fold more potent than vancomycin, and up to 2-fold more potent than teicoplanin against staphylococci. Teicoplanin was more active against enterococci (MIC90 = 0.25 microg/mL) than TLV or vancomycin (MIC90 = 1 microg/mL and 2 microg/mL, respectively), but less active against coagulase-negative staphylococci (MIC50 = 2 microg/mL). Daptomycin MIC values were similar to TLV against staphylococci and *S. pyogenes*, but were elevated for *S. agalactiae* (MIC90 = 0.25 microg/mL), other *Streptococcus* spp. (MIC90 = 1 microg/mL) and vancomycin-resistant enterococci (MIC90 = 2 microg/mL for *E. faecalis* and MIC50 = 2 microg/mL for *E. faecium*/*E. avium*, respectively). Linezolid MIC90 values were consistently 1–4 microg/mL.

Organism	No. of isolates	TLV MIC (μg/mL)		
		MIC range	MIC_{50}	MIC_{90}
Staphylococcus aureus	1214	0.12–1	0.5	0.5
MSSA	464	0.12–1	0.5	0.5
MRSA	750	0.12–1	0.5	0.5
CoNS	6	0.25–0.5	0.5	NA
Streptococci	201	0.015–0.12	0.06	0.06
S. pyogenes	61	0.015–0.12	0.03	0.06
S. agalactiae	46	0.06–0.12	0.06	0.06
Others*	94	0.015–0.12	0.06	0.06
Enterococci	85	0.06–1	0.5	1
E. faecalis	78	0.25–1	0.5	1
E. faecium and *E. avium*	7	0.06–0.25	0.12	NA

CoNS, coagulase-negative staphylococci; MRSA: meticillin-resistant *S. aureus*; MSSA, meticillin-susceptible *S. aureus*.
*Includes *S. acidominimus*, *S. anginosus*, *S. bovis*, *S. canis*, *S. constellatus*, *S. dysgalactiae*, *S. dysgalactiae ssp. equisimilis*, *S. intermedius*, *S. mitis*, *S. oralis*, *S. pneumoniae* and *viridans* group streptococci.

Conclusions: TLV was active against Gram-positive pathogens common in cSSSIs. Based upon MIC90, TLV was among the most active agents tested. These data highlight the potential therapeutic use of TLV in the treatment of cSSSIs due to Gram-positive pathogens.

P536 Activity of telavancin against complicated skin and skin structure infection isolates according to specimen source

B.M. Benton, S.L. Barriere, M.M. Kitt, K.M. Krause (South San Francisco, US)

Objective: Telavancin (TLV) is a novel, bactericidal lipoglycopeptide with a broad and potent Gram-positive spectrum of activity. TLV's unique, multifunctional mechanism of action includes inhibition of bacterial cell wall biosynthesis and disruption of bacterial membrane function. The efficacy and safety of TLV were studied in patients with complicated skin and skin structure infections (cSSSIs) in two identical, worldwide, Phase 3 studies (ATLAS 1 and ATLAS 2). Here, we report the susceptibility testing results by infection type (major abscess, deep/extensive cellulitis, wound, burn or ulcer) for TLV against the Gram-positive isolates collected in these studies.

Methods: A total of 1506 baseline Gram-positive isolates were obtained from among the 1867 cSSSI patients enrolled in the ATLAS studies throughout North America, Europe, South Africa, South America and Asia during 2005–06. All isolates were identified and susceptibility tests were performed at a central laboratory. MIC values were determined by the CLSI broth microdilution method, using frozen reference MIC panels.

Results: See Table.

Conclusions: TLV was active against Gram-positive pathogens common in cSSSIs, irrespective of the infection site. These data highlight the potential therapeutic use of TLV in the treatment of Gram-positive cSSSIs at a variety of infection sites.

Organism	No. of isolates	TLV MIC (μg/mL)		
		MIC range	MIC_{50}	MIC_{90}
Staphylococci (1220)				
Major abscess	638	0.25–1	0.5	0.5
Deep/extensive cellulitis	303	0.12–1	0.25	0.5
Wound infection	191	0.12–1	0.5	0.5
Infected burn	16	0.25–0.5	0.25	0.5
Infected ulcer	72	0.12–1	0.5	0.5
Streptococci (201)				
Major abscess	91	0.015–0.12	0.06	0.06

Wound infection	22	0.015–0.12	0.015	0.03
Infected burn	5	0.015–0.06	0.03	NA
Infected ulcer	15	0.015–0.12	0.06	0.12
Enterococci (85)				
Major abscess	19	0.25–1	0.5	1
Deep/extensive cellulitis	30	0.25–1	0.5	1
Wound infection	14	0.25–1	0.5	1
Infected burn	2	0.5	NA	NA
Infected ulcer	20	0.06–1	0.5	1

P537 Cell wall and membrane effects of oritavancin on *Staphylococcus aureus* and *Enterococcus faecalis*

A. Belley, B. Harris, T. Beveridge, T. Parr Jr., G. Moeck (St-Laurent, Elora, CA)

Objective: The lipoglycopeptide oritavancin (ORI) exerts rapid bactericidal activity in vitro against meticillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant *Enterococcus faecalis* (VRE), distinguishing it from glycopeptides like vancomycin (VAN). In this study, we compared the ultrastructural effects of ORI and VAN on MRSA and of ORI on VRE by transmission electron microscopy (TEM).
Methods: Exponentially-growing *S. aureus* ATCC 43300 (MRSA, 10^9 CFU) was exposed to 1 mg/L ORI or 16 mg/L VAN (16 X their respective broth microdilution minimal inhibitory concentrations) for 10 min whereas the VRE clinical isolate *E. faecalis* A5241515 was exposed to ORI at 1 mg/L (16 X its broth microdilution minimal inhibitory concentration) for 10 min. Bacteria were fixed in 2.5% glutaraldehyde, embedded and thin sectioned for TEM. TEM was performed using a Philips CM10 under standard operating conditions at 100 kV.
Results: Compared to VAN treatment, fewer cells were present in ORI-exposed MRSA samples, an indication that some cell lysis had occurred. The presence of cell ghosts (remnants of fixed lysed cells) indicated that lysis occurred mainly at the cell wall peripheral to the septum. Both ORI and VAN induced membrane inclusions; however, the effects of ORI were noticeably more pronounced. ORI had a distinct effect on the septum as evidenced by deformations and loss of the 'mid-line', a region of dense staining due to the activity of autolysins that cleave cell wall polymers during daughter cell separation. Interestingly, ORI did not affect the mid-line of the VRE isolate. VRE exposed to ORI had small, thin fibers protruding from division scars, the visible junction between existing and nascent cell wall in enterococci. These fibers probably resulted from cell wall breakdown as examination of VRE cell ghosts showed that rupture occurred at these sites. ORI-exposed VRE also exhibited membrane inclusions and septal distortions.
Conclusion: TEM data strongly suggest that ORI affected the coordination of cell division in *S. aureus*. ORI apparently induced breakdown of the cell wall at division scars in VRE. These effects on MRSA and VRE suggest that ORI may act largely during growth and division of these important pathogens.

P538 Anti-enterococcal and anti-sreptococcal activity profile of oritavancin in Europe

D. Draghi, G. Moeck, F. Arhin, C. Pillar, D. Sahm (Herndon, US; St. Laurent, CA)

Objective: Oritavancin (ORI) is a bactericidal lipoglycopeptide under clinical development for the treatment of infections caused by a variety of Gram-positive organisms (Org). Vancomycin (VAN)-resistant enterococci (VRE), in particular *E. faecium* (EM) with the vanA genotype isolated from non-hospitalised persons, are prevalent in Europe (EU). This surveillance initiative established a current in vitro activity profile of ORI against enterococci (EN) and streptococci (STR), including those resistant (R) to currently available agents.
Methods: Recent (2005) clinical isolates of *E. faecalis* (EF; n = 151), EM (n = 150), *S. pneumoniae* (SP; n = 100) and b-hemolytic streptococci ([BS]; 41 *S. pyogenes* [SPY], 26 *S. agalactiae* [SAG], 11 Group C, G and F streptococci) collected from 35 hospital sites across 14 countries in EU, were centrally tested by broth microdilution (CLSI; M7-A7). ORI assays included 0.002% polysorbate-80 throughout. ORI activity for EN was analysed according to VAN susceptibility (S) and for STR according to macrolide or penicillin (PEN) S status. Additionally, multi-drug resistance [MDR; concurrent resistance to $\geqslant$ 2 of the agents listed: PEN, cefuroxime, erythromycin (ERY), and trimethoprim-sulfamethoxazole] among SP was examined.
Results: See table.

Org	Category	N	ORI mg/L	
			MIC range	MIC_{90}
EF	All	151	⩽0.0005–1	0.25
	VAN S	132	⩽0.0005–0.5	0.06
	VAN NS	19	0.03–1	1
EM	All	150	0.008–0.5	0.12
	VAN S	117	0.008–0.25	0.03
	VAN NS	33	0.008–0.5	0.5
SPY	All	41	0.015–0.5	0.25
	ERY S	34	0.015–0.5	0.25
	ERY NS	7	0.03–0.12	NA
BS	All	11	0.001–0.12	0.12
	ERY S	7	0.001–0.12	NA
	ERY NS	4	0.03–0.12	NA
SP	All	100	⩽0.0005–0.015	0.008
	PEN S	67	⩽0.0005–0.015	0.008
	PEN I	18	0.001–0.008	0.008
	PEN R	15	0.002–0.015	0.008
	MDR	26	0.002–0.015	0.008
	Non-MDR	74	⩽0.0005–0.015	0.008
SAG	All	26	0.03–0.25	0.25
	ERY S	20	0.03–0.25	0.25
	ERY NS	6	0.06–0.25	NA

NA = not applicable for <10 isolates; NS = non-susceptible (intermediate and R).

Conclusions: ORI showed potent activity against all EN; however, the ORI MIC90 was higher for VAN NS versus VAN S enterococci. Based on MIC90, ORI was active against all STR, regardless of resistance phenotype. Based on these findings, ORI offers promise for the treatment of infections caused by EN or STR, including those R to currently used agents.

P539 In vitro activity profile of oritavancin against resistant staphylococcal populations from a recent surveillance initiative in Europe

D. Sahm, G. Moeck, C. Pillar, F. Arhin, D. Draghi (Herndon, US; St. Laurent, CA)

Objectives: Oritavancin (ORI), currently in clinical development for use in the treatment of infections caused by Gram-positive bacteria, is a potent bactericidal lipoglycopeptide. ORI has previously shown potent activity against staphylococci (STA), including resistant (R) strains. This surveillance (SUR) initiative was undertaken to profile the in vitro activity of ORI against drug-R and multi-drug resistant (MDR) STA in Europe (EU).

Methods: Recent (2005–2006) clinical isolates of *S. aureus* (SA; n = 557) and coagulase-negative staphylococci (CoNS; n = 78) from hospital sites in EU (48 sites; 15 countries), were centrally tested by broth microdilution (CLSI; M7-A7) against ORI and relevant comparators. ORI assays included 0.002% polysorbate-80 throughout. ORI activity was analysed for STA according to oxacillin (OX) susceptible (S) status and MDR phenotypes. MDR was defined as concurrent R to ⩾3 of the following agents: ciprofloxacin (CIP), clindamycin (CLI), erythromycin (ERY), gentamicin (GEN), Ox, quinupristin-dalfopristin, trimethoprim-sulfamethoxazole (SXT), vancomycin, daptomycin (non-susceptible [NS]), and linezolid (NS).

Results: 58.9% of SA and 61.5% of CoNS had an MDR phenotype. The most prevalent MDR phenotypes among SA included 16.7% CIP-R, ERY-R, and OX-R; and 16% CIP-R, ERY-R, OX-R, and CLI-R. Among CNS, 24.4% were 6-drug R which included CIP, CLI, ERY, GEN, OX, and SXT.

Organism	Phenotype	N	ORI mg/L	
			MIC range	MIC_{90}
SA	All	557	0.008–4	0.25
	Ox S	152	0.008–0.25	0.12
	Ox R	405	0.015–4	0.25
	MDR	328	0.008–4	0.25
	Non-MDR	229	0.015–0.25	0.25
CoNS	All	78	0.008–1	0.25
	Ox S	22	0.008–1	0.25
	Ox R	56	0.015–1	0.25
	MDR	48	0.015–1	0.25
	Non-MDR	30	0.008–1	0.25

Conclusions: SUR studies are essential for reviewing current trends in in vitro susceptibility patterns among antimicrobial agents used to treat serious infections. ORI had potent and consistent activity against a diverse EU collection of staphylococci which included OX-R and MDR phenotypes.

P540 Comparison of oritavancin versus vancomycin as treatment for clindamycin-induced *C. difficile* ribotype 027 infection in a human gut model

S. Baines, R. O'Connor, K. Saxton, J. Freeman, M. Wilcox (Leeds, UK)

Objectives: *C. difficile* infection (CDI) is a nosocomial disease of increasing importance. First line treatment is limited currently to metronidazole or vancomycin (VAN). Recent reports have questioned the efficacy of current therapies for CDI, particularly against an apparently hypervirulent *C. difficile* (CD) strain, PCR ribotype 027 (NAP1/BI). Oritavancin (ORI) is a lipoglycopeptide with activity against Gram-positive bacteria, including drug-resistant pathogens. We evaluated the efficacy of ORI and VAN in treatment of clindamycin-induced CDI in separate experiments in an in vitro human gut model.

Methods: CD PCR ribotype 027 was used in both experiments. Clindamycin instillation was used to achieve human gut concentrations and to induce CD spore germination, proliferation and high-level cytotoxin production. ORI and VAN were instilled at levels equivalent to expected human faecal concentrations. Gut flora and CD (vegetative cells and spores) were recovered and enumerated using selective media and viable counting. CD toxin was detected by cytotoxin assay.

Results: Clindamycin exposure elicited CD proliferation and high-level (5RU) cytotoxin production in both experiments on day 35. ORI and VAN levels peaked at 52 and 1144 mg/L in vessel 3, respectively. VAN instillation reduced vegetative CD counts within 1 day but did not affect CD spore counts. On day 2 of ORI instillation both CD total and spore counts declined by approx 2 logs cfu/mL; on day 3 counts were below the limits of detection and remained so during the rest of ORI instillation. Centrifugation and washing of culture samples, in addition to exposure to activated charcoal (20–40g/L) did not enhance recovery of *C. difficile*. Cytotoxin titres declined to the limits of detection in both experiments but did so 5 days sooner in the VAN experiment. Further CD proliferation and high-level cytotoxin production occurred 12 days after the end of VAN instillation, whereas CD in the ORI experiment was only sporadically isolated at the limits of detection.

Conclusion: Both ORI and VAN were effective in treating clindamycin-induced CDI in a human gut model, but only ORI appeared active against spore forms of CD. Recurrence of toxin production was observed following VAN instillation but not ORI. These results suggest that ORI should be as effective as VAN in treating CDI, and may prevent recrudescence of CD spores.

P541 Dalbavancin (DECIDE) tested against indicated Gram-positive species in European medical centres: results from France

R. Leclercq, C. Soussy, Y. Rio, M. Roussel-Delvallez, J. Etienne, D. Biedenbach, R. Jones (Caen, Creteil, Metz, Lille, Lyon, FR; North Liberty, US)

Objective: To assess the dalbavancin (DAL) spectrum and potency when tested against recent clinical isolates from five medical centres in France from October to December, 2007 (374 strains).

Methods: Standardised and reference-quality susceptibility (S) methods of agar diffusion were applied by each investigator. Etest (ET; AB BIODISK, Solna, Sweden) and CLSI (M2-A9) disk diffusion (DD) tests were performed with concurrent quality control (CLSI M100-S17, 2007) and repeated testing of strains showing unusual resistance (R) patterns in linezolid (LZD)-R, vancomycin (VAN) or DAL-non-S. A total of 374 strains were tested against DAL and VAN by ET; and LZD, cefoxitin (meticillin susceptibility surrogate), levofloxacin (LEV), gentamicin (GEN), tetracycline (TC), erythromycin (ERY), clindamycin (CC; plus D-test, penicillin (PEN) and ceftriaxone (CRO) by DD. All five French sites had acceptable quality control results. DAL-S was defined at ⩽0.25 mg/L for staphylococci and streptococci.

Results: DAL exhibited ⩾16-fold greater activity than VAN against the 251 *S. aureus* (MIC50/90, 0.094/0.125 mg/L), 50 coagulase-negative staphylococci (CoNS; MIC50/90, 0.064/0.125 mg/L) and 73 beta-haemolytic streptococci (BHS; MIC50/90, ⩽0.016/0.032 mg/L). The most common beta-streptococci group was *S. pyogenes* (approx. 60% of strains). MRSA rates were uniform from 20 to 29% (average at 25%) among sites and S rates across all staphylococci were LZD (100%), LEV (55–74%), ERY (59–73%), CC (80–86% with additional 9–18% inducible R), TC (93–94%) and GEN (63–98%). D-test positive rates in BHS and CoNS were 0 and 47% of ERY-R/CC-S isolates, respectively. LEV-R BHS (one each of gr. A and G) were detected in Paris. The most elevated DAL MIC results were 0.25 mg/L (two strains, SA and CoNS) from Paris and Lyon.

Conclusions: DAL, a novel glycolipopeptide (t1/2 at 6–8 days; once weekly dosing) showed high activity (MIC90 range, ⩽0.032–0.125 mg/L) against tested staphylococci and BST from France. The documented DAL activity (⩾16-fold greater than VAN) exhibited wide

spectrum of coverage of contemporary Gram-positive pathogens endemic to the five centres including strains R to other antimicrobial classes.

Table: Comparative activity of DAL in France (5 sites)

Method/Antimicrobial	% S activity by pathogen (no.)		
	S. aureus (251)	CoNS (50)	BHS (73)
Etest			
Dalbavancin	100	100	100
Vancomycin	100	100	100
Disk diffusion			
Linezolid	100	100	99
Erythromycin	73	59	73
Clindamycin[a]	86 (9)	80 (18)	73 (0)
Levofloxacin	74	55	94
Oxacillin[b]	75	49	NT

a. Includes % R results with D-test inducible CC-R in parentheses.
b. MRSA rate was 25% tested by cefoxitin disks (⩽21 mm); and all BHS were CRO- and PEN-S.

P542 Comparative activity of dalbavancin tested against indicated Gram-positive species in Europe: results from two Spanish medical centres (DECIDE Program)

R. Canton, A. Pascual, D. Biedenbach, R. Jones (Madrid, Seville, ES; North Liberty, US)

Objective: To assess the activity of dalbavancin (DAL) tested against recent clinical Gram-positive isolates from two medical centres in Spain over the time interval of October to December, 2007. DAL has documented activity comparable to glycopeptides (vancomycin [VAN] and teicoplanin), a prolonged elimination half-life and clinical success in trials for complicated skin and skin structure infections. Potency of DAL was determined separately in five European nations to monitor potential geographic variations against indicated species.

Methods: Standardised and reference quality susceptibility (S) methods of agar diffusion were applied by each investigator. Etest (ET; AB BIODISK, Solna, Sweden) and CLSI (M2-A9) disk diffusion (DD) tests were performed with concurrent quality control (CLSI M100-S17, 2007) and repeated testing of strains showing unusual resistance (R) patterns of linezolid (LZD)-R, and VAN or DAL-non-S. A total of 150 strains were tested against DAL and VAN by ET, and LZD, cefoxitin (for meticillin testing), levofloxacin (LEV), gentamicin (GEN), tetracycline (TC), erythromycin (ERY), clindamycin (CC; plus D-test), penicillin (PEN) and ceftriaxone (CRO) by DD. All sites had acceptable control results using three QC strains. DAL-S was defined as ⩽0.25 mg/L.

Results: DAL exhibited high potency against the 100 *S. aureus* (MIC50/90, 0.047/0.094 mg/L), coagulase-negative staphylococci (CoNS; MIC50/90, 0.047/0.125 mg/L) and beta-haemolytic streptococci (BHS; MIC50/90, ⩽0.016/⩽0.016 mg/L). This activity (MIC50 comparison) was 16-, 32- and 64-fold greater than VAN, respectively. MRSA rates varied from 6 to 24 (15% overall) between sites and *S. aureus* S rates were LZD (100%), LEV (82%), ERY (75%), CC (96% with additional 9% inducible R). D-test positive rates in CoNS were 5%; overall CC-R was at 35%. Meticillin R did not adversely influence DAL activity. All BHS (63% *S. pyogenes*) were PEN- and CRO-S. GEN (75–95% S) and TC (85–96% S) were modestly active versus the *S. aureus* and CoNS strains.

Conclusions: DAL, a novel long-acting glycolipopeptide (once weekly dosing) demonstrated high activity (MIC90 ranges, ⩽0.016–0.125 mg/L) against tested staphylococci and BHS from Spanish hospitals. The highest recorded MIC was 0.25 mg/L, confirmed in a CoNS from Madrid. The exhibited DAL potency (⩾16-fold greater than VAN) appears to cover contemporary Gram-positive pathogens endemic in this area of Europe.

Comparative activity of DAL in Spain

Antimicrobia1	% S activity by pathogen (no.)		
	S. aureus (100)[a]	CoNS (20)	BHS (30)[b]
Dalbavancin	100	100	100
Vancomycin	100	100	100
Linezolid	100	100	100
Erythromycin	75	50	87
Clindamycin[c]	87	65	90
Levofloxacin	82	50	90
Ceftriaxone	NT	NT	100

a. MRSA rate was 15%.
b. Includes gr. A (19), gr. B (3), gr. C (2), gr. F (2) and gr. G (4), and all BHS were PEN-S (zone, ⩾29 mm).
c. Includes results from D-test (inducible CC-R).

P543 Daptomycin susceptibility testing of linezolid-resistant *Staphylococcus cohnii* isolates

V. Papaioannou, S. Tsiplakou, A. Stylianakis, D. Paraskevopoulou, F. Zoumpouloglou, D. Lykou, A. Koutsoukou (Athens, GR)

Objectives: Daptomycin is a cyclic lipopeptide with potent activity and broad spectrum against Gram-positive bacteria approved for the treatment of complicated skin and skin structure infections and bacteraemia, including right sided endocarditis. The aim of this study was to evaluate the susceptibility of daptomycin against 26 clinical isolates of multi-drug resistant *Staphylococcus cohnii*, all being resistant to linezolid, recovered from blood cultures.

Methods: 26 non-duplicate isolates of *Staphylococcus cohnii* were tested for susceptibility to daptomycin with the method of E-test (AB Biodisk, Solna, Sweden) according to the manufacturer's recommendations. Those isolates were isolated from blood cultures of patients hospitalised in KAT hospital during a period of approximately three years (July 2005 to November 2007). Susceptibility testing was performed using the VITEK 2 System (Biomerieux, France). MICs for linezolid were also determined with the use of E-test. Interpretation of MICs was according to CLSI guidelines.

Results: All isolates were found resistant to oxacillin, ciprofloxacin, clindamycin, erythromycin, quinupristin/dalfopristin and susceptible to gentamicin, teicoplanin, tetracyclin, trimethoprim/sulfamethoxazole, and vancomycin. Susceptibility to fucidic acid and rifampicin varied from intermediate to resistant. Most isolates were intermediately resistant to moxifloxacin except for two that were resistant. All isolates were resistant to linezolid (MIC ⩾8 mg/L) and susceptible to daptomycin with MICs ranging between 0.5 mg/L (8 isolates, 30.8%), to 0.75 mg/L (11 isolates, 42.3%) and up to 1.0 mg/L (7 isolates, 26.9%).

Conclusion: Daptomycin showed excellent in vitro activity against multi-drug resistant isolates of *Staphylococcus cohnii*. It seems to be a promising solution to such isolates of Gram-positive bacteria while other therapeutic options such as linezolid, teicoplanin and quinupristin/dalfopristin are being eliminated by increasing resistance.

P544 In vitro time-kill studies of oritavancin against drug-resistant isolates of *Staphylococcus aureus*

G.A. McKay, S. Beaulieu, F.F. Arhin, T.R. Parr Jr., G. Moeck (Ville Saint Laurent, CA)

Background: Oritavancin (ORI), a semi-synthetic lipoglycopeptide, exerts bactericidal activity against Gram-positive bacteria including vancomycin (VAN)-resistant *S. aureus* and enterococci. To characterise ORI activity in vitro we performed time-kill (TK) experiments against *S. aureus* of clinical importance, including recent antibiotic-resistant isolates.

Methods: 6 strains of *S. aureus* (1 meticillin-resistant [MRSA], 1 community-acquired [CA] MRSA, 1 linezolid-resistant MRSA, 1 heterogeneous VAN-intermediate [hVISA], and 2 VAN-resistant [VRSA]) were tested in TK assays based on CLSI guidelines. ORI assays included 0.002% polysorbate-80 throughout. ORI and comparators VAN, teicoplanin (TEI), linezolid (LIN) and daptomycin (DAP) were tested at static concentrations approximating their free peak (fCmax) and free trough in plasma when administered at standard doses. Cell counts were determined by serial dilution plating.
Results: ORI showed concentration-dependent killing of all strains tested: at its fCmax (predicted from a 200 mg dose in humans), ORI displayed bactericidal activity (⩾ 3 log kill relative to starting inoculum) against the MRSA, CA MRSA and linezolid-resistant MRSA within 2 h. Against VRSA, ORI demonstrated 3 log kill relative to starting inoculum within 3 h for VRS2 and 6 h for VRS1. At fCmax, ORI was bactericidal against hVISA at 24 h; at fCmax predicted from an 800 mg dose, ORI achieved 3 log kill by 6 h for this strain.
Conclusions: ORI displayed concentration-dependent killing of MRSA, VRSA, hVISA in vitro. ORI was more rapidly bactericidal against all bacteria tested than were VAN, TEI, LIN or DAP at physiologically-relevant concentrations. These data support the conclusion that ORI displays concentration-dependent bactericidal activity on recent, drug-resistant isolates of *S. aureus*.

P545 Clinical efficacy of iclaprim in complicated skin and skin structure infection: preliminary results from the ASSIST-2 clinical trial

M. Dryden, O. O'Hare, E. Sidarous, P. Hadvary, K. Islam (Winchester, Bournemouth, UK; Reinach, CH)

Objective: To compare the clinical efficacy of iclaprim (ICL) with that of linezolid (LZD) at the test-of-cure (TOC) visit in the ASSIST-2 (Arpida's Skin and Skin Structure Infection Study-2), randomised, multicentre, double-blind, Phase III clinical trial.
Methods: Patients with complicated skin and skin structure infection (cSSSI) were randomised to one of two treatment arms: intravenous ICL 0.8 mg/kg q 12 hours or intravenous linezolid (LZD) 600 mg q 12 hours and received 10–14 days treatment. Clinical cure rate at the TOC visit in the intent-to-treat (ITT) and the per protocol (PP) populations was the primary efficacy endpoint for this study. The non-inferiority margin assigned was <12.5% for the 95% confidence interval (CI) for treatment difference.
Results: The ITT population comprised 494 patients (ICL: 251; LZD: 243), with 404 of these patients eligible for the per-protocol (PP) population (ICL: 205; LZD: 195). The distribution of cSSSIs at baseline was: wound infection (45%), major abscess (30%), cellulitis (28%), infected ulcers (8%), and infected burns (7%), with little variation between the treatment groups. The most commonly isolated baseline pathogen was *Staphylococcus aureus* (309 isolates), accounting for 63% of all Gram-positive pathogens (ICL: 59%; LZD: 66%). Meticillin-resistant *S. aureus* (MRSA) represented 50% of all *S. aureus* strains (ICL: 50%; LZD: 50%). Clinical cure rates were comparable between treatment groups in the ITT population (ICL: 81.3%, 95% CI = 75.9%-85.9%; LZD: 81.9%, 95% CI = 76.5%-86.5%). In the PP population there was a small numerical difference between the two groups (ICL: 90.0%; LZD: 96.9%).However, the number of patients receiving prohibited antibiotics and being therefore excluded from the PP population was much higher in the linezolid group. In a clinically evaluable population including the patients taking prohibited antibacterial agents during the trial, the clinical cure rates were comparable (ICL: 84.7%, 95% CI = 79.3%-89.2%; LZD: 86.6%, 95% CI = 81.4%-90.9%). The 95% CI for treatment difference was –8.83% to 4.95% in the population.
Conclusions: ICL shows high efficacy in patients with cSSSI as evidenced by the high cure rates. ICL achieved the pre-specfified primary endpoint of non-inferior clinical cure rate when compared with LZD. ICL could be a useful addition to the antibacterial armamentarium for cSSSI.

P546 Dose linearity and gender-independent pharmacokinetics of intravenous iclaprim assessed in two randomised, double-blind and controlled cross-over studies

U. Ullmann, R. Brandt, P. Hadvary, K. Islam (Reinach, CH)

Objectives: Iclaprim, a new antibiotic from the class of the diaminopyrimidines, had linear pharmacokinetics (PK) in the first-in-man dose escalation studies. In order to confirm the initial PK profile of iclaprim, two more PK studies were conducted.
Methods: In two randomised, double-blind, and placebo-controlled cross-over studies the PK profile in response to iclaprim dosing was investigated. In Study A, 24 healthy subjects (12 males [m], 12 females [f]) received a single intravenous (IV) infusion (150 mL in 30 minutes) of 1.6 mg/kg, 3.2 mg/kg or placebo applying a three-way cross-over design. In Study B, 24 healthy subjects (12 m, 12 f) received a single IV infusion (150 mL in 30 min) of 0.4 mg/kg, 0.8 mg/kg or 1.6 mg/kg (150 mL in 60 min) or matching placebo applying a four-way cross-over design. Blood samples for PK assessment were taken at pre-defined time points from pre-dose until + 24 hours post-administration (p.a.). Treatments were separated by wash-out phases.
Results: The mean age of the subjects in Study A was 31.1 yrs (range 19–45) and in Study B, it was 33.5 yrs (range 20–45). PK data obtained from these two studies are shown in the following table; SD values are shown in parentheses. PK parameters such as the elimination half-life, clearance and volume of distribution were comparable within the study groups (m vs. f) and also across the studies.

Dose	$AUC_{(0-inf)}$ (ng·h/mL)			C_{max} (ng/mL)		
	Overall	Male	Female	Overall	Male	Female
Study A						
1.6 mg/kg	4550 (1189)	4475 (977)	4619 (1395)	1519 (337)	1545 (232)	1495 (420)
3.2 mg/kg	9265 (2899)	9572 (2830)	8984 (3057)	2900 (553)	2921 (478)	2881 (635)
Study B						
0.4 mg/kg	1030 (281)	1003 (262)	1063 (313)	382 (79)	376 (91)	388 (66)
0.8 mg/kg	2082 (709)	2175 (712)	2004 (729)	831 (245)	866 (294)	801 (204)
1.6 mg/kg	4017 (1524)	4005 (1308)	4029 (1773)	1139 (290)	1109 (329)	1169 (256)

Conclusion: IV iclaprim PK after single doses (0.4 up to 3.2 mg/kg) exhibits dose linearity. The PK profile of iclaprim is independent of gender.

P547 Assessment of safety and tolerability profiles after iclaprim administration in complicated skin and skin structure infection from the ASSIST-2 clinical trial (Arpida's Skin and Skin Structure Infection Study-2)

P. Hadvary, M. Dryden, M. O'Hare, E. Sidarous, W. Danker, A. Leighton, K. Islam (Reinach, CH; Winchester, Bournemouth, UK; Durham, US)

Objective: To compare the safety and tolerability of iclaprim (ICL) with that of linezolid (LZD) in the ASSIST-2, randomised, multicentre, double-blind, Phase III clinical trial.
Methods: Patients with cSSSI were randomised to one of two treatment arms: intravenous ICL 0.8 mg/kg q 12 hours or 600 mg intravenous LZD q 12 hours and received 10–14 days treatment. The use of systemic or topical antibiotics, steroids or Type IA/III anti-arrhythmic drugs was prohibited during the study. Concomitant aztreonam and/or metronidazole were allowed.

Results: Safety and tolerability data were obtained from 494 patients in the ITT population (ICL: 250; LZD: 244). Treatment-emergent adverse events (AEs) were reported in 56% of patients (ICL 54%; LZD 59%). In general, ICL was better tolerated than LZD, with fewer patients reporting AEs in all categories (drug-related, severe, serious, and those that led to discontinuation of the patient from the study). The AEs were generally mild to moderate in intensity in both treatment arms. A listing of AEs that were possibly or probably related to study drug (>5%) is shown in the table.

Table: AEs possibly or probably related to study drug in >2% of patients

System organ class	ICL, n (%)	LZD, n (%)
Blood and lymphatic system disorders	0	7 (2.87%)
Gastrointestinal disorders	24 (9.60%)	38 (15.6%)
General disorders and administration site conditions	12 (4.80%)	10 (4.10%)
Infections and infestations	4 (1.60%)	7 (2.87%)
Investigations	31 (12.4%)	27 (11.1%)
Metabolism and nutrition disorders	3 (1.20%)	5 (2.05%)
Nervous system disorders	16 (6.40%)	26 (10.7%)
Psychiatric disorders	6 (2.40%)	1 (0.41%)
Respiratory and thoracic disorders	1 (0.40%)	8 (3.28%)
Skin and subcutaneous tissue disorders	13 (5.20%)	12 (4.92%)

Conclusions: ICL exhibits a good safety profile and was well tolerated in patients suffering from cSSSI. AEs of generally mild to moderate intensity were observed. These results indicate that iclaprim has an excellent safety and tolerability profile in patients with cSSSI.

P548 Analysis of the effect of iclaprim on the QT interval in the ASSIST-2 clinical trial

P. Hadvary, M. Dryden, M. O'Hare, W. Danker, K. Islam (Reinach, CH; Winchester, Bournemouth, UK; Durham, US)

Objective: To assess the effect of ICL on QT prolongation in the ASSIST-2 (Arpida's Skin and Skin Structure Infection Study-2), a randomised, multicentre, double-blind Phase III clinical trial.
Methods: Patients with cSSSI were randomised to one of two treatment arms: intravenous ICL 0.8 mg/kg q 12 hours or intravenous linezolid (LZD) 600 mg q 12 hours and received 10–14 days treatment. ECG monitoring was carried out as part of the safety evaluation of these patients and was performed at the following time points: Screening (within 1 day of study entry), Day 1 pre- (Baseline; BL) and post-dose, and Day 4 (post-dose).
Results: The ITT safety population comprised 494 patients (ICL: 250; LZD: 244). QT prolongation data corrected according to Bazett's formula (QTcB) are summarised in the Table.

Table: Mean value and mean change from BL in QTcB measurements

	ICL		LZD	
	Mean value (ms)	Mean change from BL (ms)	Mean value (ms)	Mean change from BL (ms)
BL (Day 1 pre-dose)	n = 249		n = 243	
mean (SD)	424.9 (24.7)	–	425.1 (23.8)	–
Day 1 post-dose	n = 243		n = 240	
mean (SD)	432.7 (27.1)	7.8 (13.7)	426.7 (23.8)	1.9 (11.9)
Day 4 post-dose	n = 240		n = 235	
mean (SD)	428.9 (26.5)	4.2 (18.0)	425.5 (24.8)	0.7 (17.4)

The mean QTcB change from BL on Day 1 (post-dose) was 7.8±13.7 ms and 1.9±11.9 ms in the ICL and LZD treatment groups, respectively. On Day 4 (post-dose), the mean change from BL was smaller; 4.2±18.0 ms (ICL) and 0.7± 17.4 ms (LZD). Three patients in the ICL treatment arm were reported to have median QTcB intervals of >500 ms after dosing on Day 1 and Day 4, compared with no patients in the LZD group. One patient and 0 patients in the ICL and LZD groups respectively had an increase of >60 ms from BL in QTcB interval on Day 1 post-dose, and no patients exhibited this increase on Day 4 post-dose. The percentage of cardiac adverse events possibly or probably related to study drug was higher in the LZD group (ICL: 0.68%, LZD: 1.4%), and no cardiac events were attributable to QTc prolongation.
Conclusions: Intravenous ICL tended to induce a small, transient prolongation of the mean QTc interval by approximately 4–6 ms post-dose. No cardiovascular adverse events related to QTc elevation were reported.

P549 Lack of effect of the novel antibiotic iclaprim on the anticoagulant activity and the pharmacokinetics of warfarin in healthy subjects

P. Zeman, D. Trenk, M. Cap, S. Leggewie, E. Stengele, P. Hadvary, K. Islam (Reinach, CH; Bad Krozingen, DE)

Objectives: The aim of this study was to investigate the potential drug-drug interaction between the novel antibiotic iclaprim and the anticoagulant drug warfarin in healthy subjects.
Methods: This was an open-label, randomised, two-period cross-over study in twelve healthy male subjects. Administration of either a single oral dose of warfarin 25 mg alone (W) or a single oral dose of warfarin 25 mg on day three of an eight-day steady-state intravenous (IV) iclaprim treatment regimen (W+I) was performed. The treatment periods were separated by a washout period of at least 12 days. Plasma pharmacokinetics (PK) of R, S-warfarin and the anticoagulant activity of warfarin (INR – International Normalised Ratio) as well as PK of iclaprim were determined. Safety parameters of the warfarin and the iclaprim plus warfarin treatment regimens were assessed in addition.
Results: Total anticoagulant effect of warfarin was determined by calculation of the area under the effect vs. time curve; treatment ratio of W/W+I (AUEC: 1.059 [1.004, 1.116] 90% confidence interval) and the maximum INR observed (1.077 [1.020, 1.137]) were close to unity. Therefore, the anticoagulant activity of warfarin was not affected by concomitant treatment with iclaprim. Ratios for the area under the plasma concentration time curve (AUC0-infinity) of the more potent S-enantiomer of warfarin (1.009 [0.949, 1.074]) and the maximum plasma concentration (Cmax: 1.005 [0.947, 1.066]) were within the conventional bioequivalence ranges. Similar findings were obtained with regard to PK parameters of R-Warfarin which confirms lack of interaction between iclaprim and warfarin. Administration of warfarin during the course of iclaprim treatment had no effect on plasma PK of iclaprim determined after the first infusion as well as during steady-state of the antibiotic. Administrations of iclaprim and warfarin were well-tolerated by the study subjects.
Conclusions: Results from this study demonstrated that repeated intravenous infusions of iclaprim had no effect on the anticoagulant activity and plasma pharmacokinetics of orally administered warfarin. Thus, IV infusions of iclaprim may be administered to patients on warfarin treatment without the necessity for dose adjustments of the anticoagulant drug.

P550 Preliminary results of the microbiological efficacy of iclaprim in complicated skin and skin structure infection from the ASSIST-2 clinical trial

M. Jones, M. O'Hare, C. Burley, W. Danker, K. Islam, P. Hadvary (Reinach, CH; Bournemouth, UK; Durham, US)

Objective: To compare the clinical efficacy and microbiological cure rate of iclaprim (ICL) with that of linezolid (LZD) at the test-of-cure (TOC) visit in the ASSIST-2 (Arpida's Skin and Skin Structure Infection Study-2), randomised, multicentre, double-blind Phase III clinical trial.
Methods: Patients with cSSSI were randomised to one of two treatment arms: intravenous ICL 0.8 mg/kg q 12 hours or intravenous linezolid

(LZD) 600 mg q 12 hours and received 10–14 days treatment. By-patient, by-pathogen, and overall bacteriological response rates were secondary endpoints in this study.
Results: Of the 494 patients in the intent-to-treat (ITT) population, 376 patients had a Gram-positive pathogen isolated at baseline and were included in the modified-intent-to-treat (MITT) population (ICL: 192; LZD: 184). Gram-positive pathogens accounted for 72.3% of the total number of pathogens isolated at baseline, while *Staphylococcus aureus* (309 isolates) was the most commonly isolated pathogen at baseline from the Gram-positive group, accounting for 62.6% of all Gram-positive pathogens (ICL: 59.4%; LZD: 65.8%). Meticillin-resistant *S. aureus* (MRSA) made up almost half of all *S. aureus* strains (ICL: 49.7%; LZD: 50.0%). Clinical cure rates in both treatment arms in the MITT population were comparably high (ICL: 81.3%, LZD: 81.5%). The by-patient and by-pathogen bacteriological response for *S. aureus* (eradication/presumed eradication vs persistence) at the TOC visit are shown in the table below for the MITT population.

Bacteriological response	ICL		LZD	
	n	%	n	%
By patient	n = 192		n = 184	
Eradication	148	77	144	78
By pathogen				
S. aureus (total)	n = 149		n = 160	
Eradication	115	77	126	79
Persistence	21	14	12	8
MRSA	n = 74		n = 80	
Eradication	55	74	60	75
Persistence	10	14	8	10

Conclusions: ICL shows good clinical and microbiological efficacy against *S. aureus*, including MRSA, the major causative pathogen in cSSSI. These rates were comparable to those observed for LZD. ICL could constitute a useful antibacterial for the treatment of cSSSI including infections caused by MRSA.

P551 Pre-clinical studies of a new quinolone (UB-8902) against *Acinetobacter baumannii* resistant to ciprofloxacin

R. López-Rojas, J. Sánchez-Céspedes, F. Docobo-Pérez, J. Vila, J. Pachón (Seville, Barcelona, ES)

Objectives: To evaluate the in vitro and in vivo activity of a new derivative of ciprofloxacin (UB-8902) against *Acinetobacter baumannii*.
Methods: We used two *A. baumannii* strains (Ab58 and Ab661). The antibiotics of the study were ciprofloxacin, moxifloxacin, and the new generated quinolone UB-8902. Animals used were immunocompetent C57BL/6 female mice.
In vitro tests: MIC (microdilution method) and bactericidal activity (time-kill curves) were performed following CLSI recomendations.
In vivo assays: we studied the toxicity parameters of the UB-8902 [lethal dose 0 (LD0), lethal dose 50 (LD50), and lethal dose 100 (LD100)] inoculating groups of 6 animals with rising concentrations in base 2 of UB-8902, from 0.5 mg/kg/ip to reach a 100% of mortality (Reed and Muench method). To ascertain the bacterial minimum lethal dose (MLD) and the bacterial lethal dose 50 (BLD50) of the strains Ab58 and Ab661, groups of 10 animals were inoculated (using a murine model of peritoneal sepsis) with a potentially lethal concentration (8 log cfu/mL), and decreasing in base 10 until reaching the minimum which caused a 100% of mortality. To study the effective dose 50 (ED50) of UB-8902, we used a model of peritoneal sepsis with groups of 10 animals with an inoculum similar to the MLD of the strains, and treated with a dose of UB-8902 from 0.5 mg/kg, increasing in base 2, to LD0 or until a 50% of survival was reached.
Results: MICs (mg/L): Ab58, CIP = 0.25, MOX=0.016, UB-8902=0.03; Ab661, CIP=8, MOX=1, UB-8902=0.5. In time-kill curves for Ab58, bactericidal activity was observed from 4 h with 4xCMI of UB-8902, from 8 h with 4xCMI of CIP, and there was no bactericidal activity with MOX. For Ab661, bactericidal activity was observed from 4 h with 4xCMI of UB-8902, from 4 h with 4xCMI and from 8 h with 2xCMI of CIP, and from 8 h with 2xCMI and 4xCMI of MOX. The toxicity parameters of UB-8902 (mg/kg) were: LD0=512, LD50=608.5, LD100=2048. The MLD was 7.5 log cfu/mL for both strains, being BLD50 of Ab58 6.11 log cfu/mL and 7 log cfu/mL for Ab661. The ED50 of UB-8902 for Ab58 was 16 mg/kg, and for Ab661 was 128 mg/kg.
Conclusions: The new quinolone UB-8902 presents bactericidal activity against *A. baumannii* resistant to ciprofloxacin and is effective in reducing the mortality in a model of murine peritoneal sepsis, with a dose lower than the toxic one, which warrants the future assessment of its efficacy in other in vivo experiments, such as a discriminative murine model of pneumonia.

P552 Intracellular penetration and activity of the new fluoroquinolone UB-8902 in human polymorphonuclear leukocytes

S. Ballesta, I. García, J. Sánchez-Céspedez, J. Vila, A. Pascual (Seville, Barcelona, ES)

Background: UB-8902, a 7-(4-methyl)-piperazine ciprofloxacin derivative, is a new fluorquinolone that shows higher in vitro activity than ciprofloxacin. The uptake of UB-8902 by human polymorphonuclear leukocytes (PMN) and its intracellular activity against isogenic strains of *Staphylococcus aureus* with sequential mutations in gyrA and/or parC genes were also evaluated.
Methods: Uptake of UB-8902 by PMNs was determined by a fluorometric assay. The effect of cell viability, environmental conditions, metabolic inhibitors, potential competitive substrates and PMN-stimuli on intracellular uptake was also studied. The intracellular activity was determined by incubation of PMN containing intracellular bacteria in the presence of UB-8902. Wild-type and mutant *S. aureus* with mutation in gyrA and/or parC were used for the killing assays.
Results: UB-8902 uptake by PMN was rapid and saturable at extracellular concentrations higher than 10 mg/L. At extracellular concentrations of 2 mg/L, the cellular to extracellular concentration (C/E) ratio was 6.5 ±0.8. The efflux of UB-8902 from PMN was also a rapid process. The intracellular penetration of UB-8902 was slightly increased when dead cells were used (7.6±1.3 versus control 6.5±0.8) and unaffected at 4ºC (C/E ratio 6.3±1.5). The uptake of UB-8902 by PMN was significatly affected by the extracellular pH (intracellular penetration decreased at basic pH and increased at acid pH). Sodium cyanide, an inhibitor of mitochondrial oxidative metabolism, significantly impaired intracellular penetration of UB-8902 (C/E ratio: 3.3±1.4). The ingestion of opsonised zymosan significantly increased the levels of PMN-associated UB-8902 (C/E ratio: 9.9± 1.3). Neither cell stimulation by phorbol myristate acetate (PMA) nor ingestion of opsonised *Staphylococcus aureus*, modified the uptake (C/E ratio:7.1±0.8 and 7.0±1.0 respectively). At extracellular concentrations evaluated, 0.125, 1 y 5 mg/L, UB-8902 significantly decreased the intracellular survival of wild-type *S. aureus*. For the mutant strains, UB-8902 only showed significant intracellular activity at extracellular concentration higher than 1 mg/L.
Conclusions: UB-8902 penetrates into PMN, reaching high intracellular concentrations and it remains active intracellularly against *S. aureus*.

P553 Definition of wildtype MIC distributions for targeted species for determination of optimal dosing for zabofloxacin, a novel fluoronaphthyridone

R. Jones, P. Ambrose, M. Wikler (North Liberty, Albany, San Diego, US)

Objectives: Zabofloxacin (formerly DW-224a) is a new quinolone-like agent with potent activity against pathogens responsible for

respiratory tract and uncomplicated skin and skin structure infections (*S. pneumoniae* [SPN], *H. influenzae* [HI], *M. catarrhalis* [MCAT] and *S. aureus* [SA]). Zabofloxacin was evaluated by CLSI MIC methods for subsequent PK/PD target attainment (TA) analysis to optimise doses used in various clinical trials.

Methods: Recent (2006) wildtype clinical isolates from worldwide locations (Europe, Asia, North and South America) were susceptibility (S) tested by CLSI methods: SPN (225; 200 wildtype, 25 levofloxacin-resistant [LEVO-R]); SA (200 wildtype, 200 MRSA and LEVO-R; 25 CA-MRSA); HI (55 wildtype); MCAT (10 wildtype) and CoNS (40 wildtype with 20 LEVO-R). Zabofloxacin was compared to LEVO, gemifloxacin [GEMI] and moxifloxacin [MOXI]. PK/PD studies of TA were calculated by Monte Carlo simulation from this MIC distribution for doses 50–800 mg daily (protein binding at 77%).

Results: Wildtype SPN and SA (MIC90, 0.03 mg/L); and HI and MCAT (MIC90, 0.015 mg/L were very zabofloxacin-S. In contrast, LEVO-R SPN (MIC90, 1 mg/L) and MRSA (MIC90, >8 mg/L) had higher zabofloxacin MIC values. CA-MRSA were zabofloxacin-S (also LEVO-S). Beta-lactamases and PBP-mediated resistances did not adversely influence zabofloxacin potency. Zabofloxacin (MIC50, 0.015 mg/L) was two- and eight-fold more potent than GEMI and MOXI versus wildtype penicillin-R SPN. 90% TA was achieved against SPN, HI, and MCAT wildtype pathogens (MIC, ⩽0.06 mg/L; ⩾300 mg/day) and many LEVO-R SPN.

Target pathogen (no.)[a]	Zabofloxacin MIC (mg/L)			MIC 90% (mg/L)		
	50%	90%	Range	GEMI	LEVO	MOXI
SPN, WT (200)	0.015	0.03	⩽0.0004–0.06	0.03	1	0.25
SPN, PCN-R (101)	0.015	0.03	0.008–0.06	0.03	1	0.25
SPN, LEVO-R (25)	0.12	1	0.06–8	1	>8	8
HI, WT (55)	0.008	0.015	⩽0.004–0.03	0.008	0.015	0.03
MCAT, WT (10)	0.015	0.015	0.008–0.015	0.015	0.03	0.06
MSSA, LEVO-S (200)	0.03	0.03	0.008–0.12	0.03	0.25	0.06
MSCoNS, LEVO-S (20)	0.03	0.03	0.008–0.03	0.03	0.25	0.12

a. PCN = penicillin, WT = wildtype.

Conclusions: Zabofloxacin was two- to 16- and two- to >64-fold more active than MOXI or LEVO, respectively; equal to GEMI versus RTI pathogens and wildtype MSSA. Optimal dosing appears to be achievable due to high zabofloxacin potency versus these 755 contemporary clinical strains. Clinical trial designs and PK/PD-based dosing regimens will be optimised for this promising, new orally administered agent.

P554 Tigecycline in intensive care unit infections

E. Paramythiotou, F. Kontopidou, E. Papadomichelakis, A. Antoniadou, G. Poulakou, A. Armaganidis, H. Giamarellou (Athens, GR)

Objectives: Tigecycline is a novel broad-spectrum glycylcycline antibiotic, which possesses activity against a broad range of Gram-positive, Gram-negative, atypical, anaerobic and antibiotic-resistant bacteria. It has been approved for complicated infections of skin and/or subcutaneous tissues and complicated intra-abdominal infections. For compassionate use it has been given for the treatment of infections caused by multi-resistant organisms. The aim of this study was to assess the efficacy of tigecycline in ICU infections caused by strains resistant to other antibiotics.

Methods: This is a prospective study conducted in the 18-bed medical–surgical ICU of "ATTIKON" university general hospital. Patients with severe ICU infections treated with tigecycline were included. Tigecycline was used either in cases of infections caused by pan-drug resistant Gram-negative microorganisms, including colistin, or as empirical treatment in patients with life-threatening infections which did not respond in other treatment or were colonised by PDR pathogens. Data recorded included demographic characteristics; site of infection, other antibiotics used concomitantly, treatment results after fifteen days follow up, outcome and adverse drug reactions.

Results: Between 12/ 2006 and 11/ 2007 seventeen patients were treated with tigecycline. Among them nine patients were treated for ventilator associated pneumonia (VAP), five for complicated skin or intra-abdominal infection and three for septic shock of unknown origin. Ten patients were treated empirically. Three patients received tigecycline as monotherapy and fourteen received other antimicrobials simultaneously. Seven cases of VAP were due to *Acinetobacter baumannii* alone and two cases were mixed respiratory infections (*Acinetobacter* b plus *Klebsiella* pn) and all of them were cured. Among the rest, one patient was cured and a temporal improvement was noted in 4/7 patients. Most of pathogens were susceptible only to colistin and tigecycline and four patients were infected with colistin-resistant strains. Dose was 50 mg × 2 or 100 mg × 2 IV without adverse effects.

Conclusions: Though the number of patients is small, our results are encouraging about tigecycline use for the treatment of ICU serious infections especially in ventilator-associated pneumonia. Given the problem of MDR pathogens in ICUs, tigecyclin could be an effective treatment choice. However more experience is urgently required.

P555 Anti-inflammatory effect of lycopene on chronic bacterial prostatitis rat model

Y.H. Cho (Seoul, KR)

Purpose: Chronic bacterial prostatitis (CBP) is the most common urological disease in adult males, with antibiotic therapy being the gold standard for its treatment. However, long-term therapy results in many side effects as well as bacterial resistance. For these reasons, there is a need for a new treatment modality to replace traditional antibiotic therapy. Lycopene, an extract of tomatoes, has antioxidant effects against various bacteria and synergistic effects with antibiotics. We evaluate the synergistic effects of lycopene on the treatment of CBP in an animal model.

Materials and Methods: Forty five rats demonstrating CBP were randomly divided into 4 groups; the control, lycopene, ciprofloxacin and lycopene with ciprofloxacin groups. All drug treatments were conducted over a period of 2 weeks. After treatment, the results were analysed, with the microbiological cultures and histological findings of the prostate and urine samples compared with the control group and between each group.

Results: The uses of ciprofloxacin, and lycopene with ciprofloxacin showed statistically significant decreases in bacterial growth and improvements in prostatic inflammation compared with the control group ($p < 0.05$). The lycopene with ciprofloxacin group showed a statistically significant decrease in bacterial growth and improvements in prostatic inflammation compared with the ciprofloxacin group ($p < 0.05$).

Conclusions: These results suggest that lycopene may be an effective material in the treatment of CBP. Especially, the combination treatment of lycopene and ciprofloxacin has synergistic effects. Therefore, it is suggest that the combination of lycopene and ciprofloxacin may be effective in the treatment of CBP, and with a higher success rate.

P556 Efficacy of doripenem against *Pseudomonas aeruginosa* in nosocomial pneumonia, including ventilator-associated pneumonia

J. Chastre, J. Jiang, K. Kaniga, I. Friedland (Paris, FR; Mountain View, US)

Objectives: Doripenem (DOR, a new carbapenem for which an MAA has been submitted in the EU) has potent activity against bacterial pathogens commonly responsible for nosocomial pneumonia, including ventilator-associated pneumonia. In two open-label, multicentre clinical trials of patients with nosocomial pneumonia, the efficacy of DOR against *P. aeruginosa* was compared with piperacillin/tazobactam (PTZ) in non-ventilator-associated pneumonia and early-onset (<5 days) ventilator-associated pneumonia patients (Study 1), and to imipenem (IMI) in early-onset and late-onset (⩾5 days) ventilator-associated pneumonia patients (Study 2).

Methods: Adults in Study 1 were randomised to treatment for 7–14 days with 1-h infusion of IV DOR 500 mg q8h or 30-min infusion of IV PTZ 4.5 g q6h. After 72 h of IV study drug, patients were allowed to be switched to oral levofloxacin 750 mg QD. Adults in Study 2 were randomised to treatment with 7–14 days of IV DOR 500 mg q8h as a 4-h infusion or IV IMI 500 mg q6h for 30 min or 1000 mg q8h for 60 min. No oral switch was allowed. Clinical cure rates at the end of treatment were measured in the microbiologically evaluable patients (those who completed the study and had at least one bacterial lower respiratory tract pathogen identified at baseline that was susceptible to the study drug received).
Results: Overall clinical cure rates in microbiologically evaluable patients were 82.1% (69/84) with DOR versus 78.3% (65/83) with PTZ, and 69% (80/116) with DOR versus 64.5% (71/110) with IMI. The pooled clinical cure rates from both studies in microbiologically evaluable patients with *P. aeruginosa* was 81.6% (31/38) with DOR versus 54.8% (17/31) in the pooled comparators. The 95% CI of the 26.7% difference (2.4; 51.1) did not cross 0. The comparison within each trial was 83.3% [15/18] DOR versus 70.6% [12/17] PTZ (Study 1) and 80.0% [16/20] DOR versus 42.9% [6/14] IMI (Study 2).
Conclusions: DOR is a potent new carbapenem that, in a post hoc analysis of pooled data, showed significantly higher cure rates than its comparators against *P. aeruginosa* in nosocomial pneumonia, including ventilator-associated pneumonia.

P557 XF-73, a novel anti-staphylococcal antimicrobial with very rapid bactericidal activity

K. Miller, N. Ooi, J.K. Hobbs, W. Rhys-Williams, W.G. Love, I. Hayter, M. Katila, I. Chopra (Leeds, Brighton, UK)

Objectives: XF-73 is the lead compound in an entirely new class of anti-microbial agents, developed to address the growing and unmet need for prophylaxis and treatment of drug resistant bacteria. It has previously been shown to be highly potent against a range of *S. aureus* strains including meticillin-sensitive *Staphylococcus aureus* (MSSA), healthcare associated meticillin resistant *S. aureus* (HA-MRSA) and community associated meticillin resistant *S. aureus* (CA-MRSA) strains. XF-73 exerts rapid bactericidal activity and the aim of this study was to further characterise this effect.
Methods: Time-kill studies for XF-73 were conducted on *S. aureus* SH1000 at 4x MIC and samples were taken and prepared for scanning electron microscopy. Membrane integrity in the presence of XF-73 was determined using the BacLight assay, which evaluates the ability of propidium iodide to penetrate into the cell following 10 minutes of drug exposure. A luciferin/luciferase assay was performed to quantify XF-73-induced leakage of intracellular ATP.
Results: SH1000 cell numbers decreased by 4.5 logs following 5 minutes exposure to 4x MIC of XF-73, and by 7 logs following 30 minutes exposure. Scanning electron micrographs following 5 and 30 minutes exposure to XF-73 showed no morphological damage of SH1000 cultures, compared with untreated cells. Nevertheless, treatment for 10 minutes with XF-73 caused complete perturbation of membrane integrity as evidenced by a 100% loss of membrane integrity in the BacLite assay compared to 0% in the absence of XF-73. ATP leakage was not observed following exposure to XF-73.
Conclusion: The rapid bactericidal activity of XF-73 is not associated with significant cellular lysis. This is consistent with the absence of morphological damage to *S. aureus* cultures exposed to XF-73 and the lack of leakage of intracellular material (ATP) after a period where cell viability is reduced by 7 logs. Membrane integrity was however perturbed, suggesting that although the cell remained physically intact, the membrane was severely damaged. Investigations are ongoing to elucidate further the mechanism of action of this highly potent and rapidly bactericidal anti-bacterial agent.

P558 XF-73: a novel antimicrobial – Investigation of the change in MIC against multiple MRSA strains during a 55-passage study

W. Rhys-Williams, W. Love, I. Hayter, D. Farrell, R. Janes, M. Robbins (Brighton, London, UK)

Objectives: XF-73, the lead compound in a new class of anti-microbial agents, has previously been shown to be potent (MIC50 1 mg/L) against a range of *Staphylococcus aureus* strains including meticillin-sensitive *S. aureus* (MSSA), healthcare-associated meticillin-resistant *S. aureus* (HA-MRSA) and community-associated meticillin-resistant *S. aureus* (CA-MRSA). XF-73 is bactericidal (MBC50 1 mg/L) and the aim of this study was to investigate the propensity of XF-73 to cause mutational resistance in common MRSA clones including USA300, responsible for the majority of CA-MRSA infections in the USA. An antibiotic comparator (fusidic acid) was also studied.
Methods: MICs were determined for XF-73 and fusidic acid using a macrodilution broth method. Five "Network on Antimicrobial Resistance in *Staphylococcus aureus*" (NARSA) strains were tested: NRS382, NRS384 (USA 300), NRS271, NRS123, NRS387. All 5 strains were passaged 55X at 0.5X MIC (determined from the previous passage) to investigate whether there was an increase in the MIC, suggestive of the development of mutational resistance.
Results: The initial MICs of XF-73 and fusidic acid were found to be 0.25–0.5 mg/L and 0.12–0.25 mg/L respectively against the 5 MRSA strains tested. For all 5 strains, a rapid increase in the MIC of fusidic acid was observed after only 2–5 repeat passages, with the MIC reaching 256 mg/L after 33–42 passages. In comparison, the MIC of XF-73 did not increase significantly (<8-fold increase), even after 55 passages.

	XF-73 MIC (mg/L)					Fusidic acid MIC (mg/L)				
	NRS 123	NRS 271	NRS 382	NRS 384	NRS 387	NRS 123	NRS 271	NRS 382	NRS 384	NRS 387
Passage 0	0.5	0.25	0.25	0.25	0.25	0.12	0.25	0.12	0.12	0.12
Passage 55	1	0.5	1	0.5	0.5	256	256	256	256	256

Conclusion: Mutational resistance to fusidic acid in *S. aureus* is an important resistance mechanism. In the UK and Australia, susceptibility to fusidic acid is defined as an MIC of ⩽0.25 mg/L or ⩽0.5 mg/L respectively and resistance is defined as an MIC of 2 mg/L or more. All 5 MRSA strains rapidly developed resistance to fusidic acid after only a few repeat passage exposures. In comparison, with XF-73 there was no significant increase in MIC against all five selected MRSA strains, even after 55 repeat passages. This suggests that the likelihood for mutational resistance development against XF-73 is remote and hence demonstrates potential for a long clinical lifetime.

P559 XF-73: a novel antimicrobial with broad-ranging Gram-positive antibacterial activity

W. Love, W. Rhys-Williams, I. Hayter, D. Farrell, J. Curry, M. Robbins (Brighton, London, UK)

Objectives: XF-73, the lead compound in a new class of anti-microbial agents, has previously been shown to be potent (MIC50 1 mg/L) against a range of *Staphylococcus aureus* strains including meticillin-sensitive *S. aureus* (MSSA), healthcare-associated meticillin resistant *S. aureus* (HA-MRSA) and community-associated meticillin resistant *S. aureus* (CA-MRSA). XF-73 is bactericidal (MBC50 1 mg/L) and the aim of this study was to investigate its anti-bacterial activity against a range of aerobic and anaerobic Gram-positive bacteria.
Methods: MICs for XF-73 were determined against a panel of 65 Gram-positive bacterial strains (56 aerobic and 9 anaerobic) using the CLSI

broth microdilution methodology. XF-73 was used in a log2 dilution series from 0.03 to 64 mg/L. Where possible, both antibiotic resistant and susceptible strains were included.
Results: XF-73 was found to have antibacterial activity (MIC range 0.25–4 mg/L) against all 65 strains tested. The results are provided in the table.

Species (No. of isolates)	Characteristic/Phenotype/Genotype	XF-73 MIC Range (mg/L)
Staphylococcus aureus (15)	MSSA, MRSA, VISA	0.5–1
Coagulase-negative *Staphylococcus* spp. (5)	MSSE, MRSE, *S. haemolyticus*, *S. saprophyticus*	0.25–1
Enterococcus spp. (9)	Vancomycin susceptible, VanA, VanB, VanC	0.5–2
Beta-haemolytic *Streptococcus* spp. (9)	Macrolide susceptible and resistant clinical isolates	0.25–2
Alpha-haemolytic *Streptococcus* spp. (15)	Penicillin and/or macrolide resistant, multi-resistant clinical isolates	0.5–4
Corynebacterium jeikeium (2)	Clinical isolates	Both 0.25
Listeria monocytogenes (1)	Clinical isolate	0.5
Gram-positive anaerobic species (9)	*Clostridium*, *Peptostreptococcus* and *Propionibacterium* spp.	0.5–4

Conclusion: XF-73 demonstrated potent activity against all of the aerobic and anaerobic Gram-positive bacteria tested. These initial results suggest that XF-73 has potential for use as a novel antibacterial agent against a wide range of clinically relevant Gram-positive pathogens. Studies are ongoing to investigate the use of XF-73 in a range of different bacterial disease indications.

P560 In vitro and in vivo activity of SB006, a novel branched antimicrobial peptide selectively active against Gram-negative bacteria.

S. Fabiole Nicoletto, I. Baster, G. Pirri, A. Giuliani (Colleretto Giacosa, IT; Cracow, PL)

Objectives: The aim of this study was to investigate the in vitro and in vivo activity of SB006 against selected MDR Gram-negative clinical isolates.
Methods: MICs and MBCs were determined in MHB by the broth microdilution methodology, according to CLSI procedure. MIC was defined as the lowest drug concentration causing complete suppression of visible bacterial or fungal growth. MBC was defined as the antibiotic concentration that induced at least a 3 log reduction of the initial bacterial inoculum.
The in vivo activity of SB006 has been evaluated using a neutropenic mouse model of infection. Mice were infected intraperitonally using a 0.2-ml volume of a high dose inoculum (3xLD50) of *Pseudomonas aeruginosa* (clinical isolate). Several single dosages of SB006 were administered at 1 hour post-challenge. The total dose required for survival of 50% of mice at 72 h (ED50) was determined.
Results: The in vitro activity of SB006 and reference compounds against an expanded panel of clinical bacteria recently collected has been determined; all tested strains show resistance to several currently used antibacterial agents. SB006 was active against Gram-negative bacteria; the MICs of SB006 against *Acinetobacter* spp. (2 strains), *Enterobacter* spp. (4 strains), *Escherichia coli* (12 strains), *Klebsiella pneumoniae* (6 strains), *Pseudomonas aeruginosa* (16 strains), *Salmonella enteritidis* (1 strain), and *Stenotrophomonas maltophilia* (1 strain) were between 4 and 32 mg/L, while colistin showed MICs ranging between 0.25 and 8 mg/L. The MIC and MBC values of SB006 ranged between 8 and 32 mg/L, while those of colistin ranged between 0.25 and 4 mg/L. The MBC/MIC ratio was always 1 for SB006 and colistin. Moreover, in vivo studies showed that SB006 was active in an experimental mouse model of infection against a clinical isolate of *P. aeruginosa*.
Conclusion: SB006 showed good activity against different Gram-negative bacteria isolates with a potency and spectrum of antimicrobial activity comparable to those of colistin and showed to be bactericidal. As colistin, SB006 seems to selectively perturb the bacterial membrane: this mechanism of action is expected to circumvent the problem of resistance. These features make the antimicrobial branched peptide SB006 a promising template for the development of new antibacterial drugs.

P561 SASP: rapid bactericidal activity against USA strains of meticillin-resistant *Staphylococcus aureus*

A. Barnard, K. Pitts, D. Brown, A. Wilkinson, H. Fairhead (Cambridge, UK)

Objectives: SASP is a unique antibacterial protein that acts by binding to bacterial DNA and halting replication and gene expression, resulting in rapid cell death. SASPjectTM is a novel platform technology by which a SASP gene is delivered to selected bacteria via dedicated bacteriophage vectors. Previous studies using *S. aureus*-specific SASPjectTM vector, PTSA1.2/A, showed SASP is rapidly bactericidal (assessing kill at 3 h) against 163 geographically diverse clinical MRSA isolates spanning SCCmec types 1-V (10^5 cfu/ml). In this study, efficacy of SASP against MRSA strains isolated in the USA is determined by time kill assay over 24 h at higher cell densities (10^7 cfu/ml). Speed of kill of SASP against an MRSA USA300 isolate is also assessed.
Methods: Ten different MRSA isolates of different USA types were tested for susceptibility to SASP by time kill assay. Bacterial cells were grown overnight in Luria-Bertani broth supplemented with calcium chloride (10 mM), diluted to 2 x 10^7 cfu/ml and mixed with an equal volume (500 μl) of PTSA1.2/A (6 x 10^7 pfu/ml). Cultures were incubated at 35ºC, samples were removed at 0, 1, 2, 4, 6 and 24 hours and viable cells were enumerated following overnight incubation on blood agar.
Speed of kill was assessed by the same method against a clinical MRSA USA300 isolate diluted to 5 x 10^5 or 5 x 10^7 cfu/ml with viable counts performed at 0, 2, 5, 10, 15, 20, 30, 45 and 60 mins. For all controls, PTSA1.2/A was replaced with buffer.
Results: SASP was rapidly bactericidal against all 10 clinical isolates tested, with 5 isolates showing a >3-log drop in viability within 1 h and remaining isolates showing a >3-log drop in viability within 2 h.
In the speed of kill assay, SASP caused a >99.9% drop in viability within 5 mins against the 10^5 culture and a >99.9% drop in viability within 10 mins against the 10^7 culture.
Conclusions:
- SASPject vector, PTSA1.2/A can effectively deliver a SASP gene to all tested MRSA strains.
- SASP shows rapid bactericidal activity against tested MRSA strains covering different USA types.

P562 The efficacy of SASP targeted to meticillin-resistant *Staphylococcus aureus* in mixed staphylococcal cultures

K. Pitts, A. Barnard, D. Brown, A. Wilkinson, H. Fairhead (Cambridge, UK)

Objectives: SASPjectTM is a novel platform technology which allows bacterial species to be targeted with the SASP anti-bacterial protein by means of a species-specific delivery vector, without affecting the body's normal microbial flora. This study utilised a *Staphylococcus aureus*-specific SASPjectTM delivery vector, PTSA1.2/A, developed for intra-nasal elimination of MRSA. SASP has previously demonstrated rapid bactericidal activity against a wide range of clinical MRSA and meticillin susceptible *S. aureus* (MSSA) isolates. In this study the effect of co-cultures of MRSA, MSSA, *S. epidermidis* and *S. haemolyticus* on the efficacy of SASP is assessed.
Methods: *S. epidermidis* was grown overnight in Luria-Bertani broth and mixed (10^7 cfu/ml final concentration) with a clinical MRSA strain at final concentrations of 10^4, 10^5, or 10^6 cfu/ml. PTSA1.2/A (6 x 10^8 pfu/ml) was then added. Mixed cultures containing MRSA and a clinical MSSA or *S. haemolyticus* strain were similarly prepared and again supplemented with PTSA1.2/A. Appropriate mono-cultures and

PTSA1.2/A controls were also assayed. Cell viability was measured over time by performing cell counts at 0, 1, 2, 4 and 6 hours.
Results: The presence of *S. epidermidis* did not affect the rate of kill of MRSA by PTSA1.2/A, with no detectable survivors by 2 h for any of the 3 MRSA cell concentrations tested±*S. epidermidis*. Furthermore, *S. epidermidis* grew at the same rate in the presence or absence of PTSA1.2/A. A similar trend was seen with *S. haemolyticus*. PTSA1.2/A killed both MRSA and MSSA cells when co-cultured (no detectable survivors by 4 hours) and the rate of kill of MRSA (>3 log drop in viability in 2 h) was comparable in the presence or absence of MSSA.
Conclusions:
- SASP delivered by PTSA1.2/A is rapidly bactericidal against MRSA.
- Rate of kill, in the combinations tested, is unaffected by the presence of other staphylococcal species commonly found in the human nose.
- The presence of PTSA1.2/A does not affect the growth rate of other staphylococcal species, indicating that the SASPjectTM system can be used to target selected bacteria whilst leaving the normal flora intact.

P563 Evaluation of the type I signal peptidase of *Staphylococcus epidermidis* as novel antibacterial target

K. Bockstael, N. Geukens, J. Anné, P. Herdewijn, A. Van Aerschot (Leuven, BE)

Objectives: In a time of emerging bacterial resistance there is need for novel antibacterial targets. One of the bacteria of concern is *Staphylococcus epidermidis*, an opportunistic pathogen associated with foreign body infections and nosocomial sepsis.
We aim to develop antimicrobial drugs against a new target, the type I signal peptidase (SPase I). SPases I have a role in protein secretion as they remove the signal peptides from secretory proteins during or after translocation across the membrane and have been shown to be essential for the viability of the cell. *S. epidermidis* has three type I signal peptidases, Sip1, Sip2 and Sip3.
We therefore aim to evaluate the SPase I of *S. epidermidis* as a novel antibacterial target and to design, synthesize and evaluate the inhibitory activity of potential SPase I inhibitors.
Methods: For all DNA manipulations standard techniques were used. SDS-PAGE was used to analyse the overproduction of the enzymes in *Escherichia coli* after IPTG induction. Purification of His tagged enzymes was performed under native conditions using affinity chromatography on a Ni2+-NTA agarose column. SPase expression in planktonic and sessile grown *S. epidermidis* was analysed by RT-PCR experiments.
Substrate analogues were rationally designed (by modelling using the structure for the *E. coli* signal peptidase) and synthesised by solid phase peptide synthesis using classical coupling reagents for peptide bond formation and Fmoc protected amino acids. The synthesised compounds were purified by Reversed Phase-High Performance Liquid Chromatography and analysed by High Resolution Mass Spectrometry.
Inhibitory activity against SPase I was evaluated by an in vitro inhibitor assay based on intramolecular fluorescent resonance energy transfer (FRET) using an internally quenched fluorescent peptide substrate based on a *S. epidermidis* preprotein.
Results: The SPase I genes of *S. epidermidis* were cloned, expressed and purified in *E. coli* and biochemically analysed. The enzymes were used to develop and optimise a FRET based in vitro assay, allowing evaluation of potential SPase I inhibitors such as rationally designed peptide substrate analogues.
Conclusion: Due to their unique properties, SPases I seem to be an attractive target for the development of new antimicrobial drugs. A FRET based in vitro assay was developed and used for the evaluation of potential SPase I inhibitors.

P564 Disruption of *Pseudomonas aeruginosa* quorum sensing using high-affinity antibodies derived from immunised sheep

S.S. Palliyil, I.D. Broadbent, K.A. Charlton, A.J. Porter (Aberdeen, UK)

Objectives: *Pseudomonas aeruginosa* is an opportunistic human pathogen which, like many other Gram-negative pathogens, employs quorum sensing – regulated virulence factors to establish an infection in its host. The bacterium is notorious for antibiotic resistance and causes life-threatening infections in immunocompromised and cystic fibrosis patients, and also accounts for 11% of nosocomial infections worldwide. Quorum sensing in *Ps. aeruginosa* populations is controlled by low molecular weight (hapten) signalling molecules known as homoserine lactones (HSLs). Previous work in our lab has demonstrated that sheep are capable of producing high affinity, high specificity anti-hapten antibodies, so we sought to develop anti-HSL antibodies derived from immunised sheep and explore their potential as novel antibacterial agents.
Methods: Derivatives of *Ps. aeruginosa* HSL molecules were synthesised, conjugated to suitable carrier proteins, and used to elicit an immune response in sheep. Post immunisation, sheep polyclonal sera were analysed using immunoassays to determine the level of specific immune response. Bioassays were also employed to demonstrate the abilities of the sera to block *Ps. aeruginosa* quorum sensing.
Results: The ability of immunised sheep polyclonal serum to bind specifically to quorum sensing molecules has been demonstrated by a series of in vitro immunoassays and bioassays. Immunisation with a mixture of three HSL subgroups resulted in high antibody titre polyclonal serum which showed nanomolar affinities to the free form of HSLs when applied in a competition format.
Conclusions: Antibodies are an attractive method for controlling bacterial virulence and biofilm formation in Gram-negative bacteria, and at the same time these ‘antipathogenic’ drugs are less likely to develop resistance in bacteria compared to conventional antibiotics.
The results from preliminary experiments are highly encouraging and demonstrate the possibility of isolating nanomolar affinity anti-HSL antibodies from immunised sheep. Phage display antibody libraries are currently being constructed from sheep peripheral blood lymphocytes, and will be screened in due course for anti-HSL monoclonal antibodies.

P565 Interaction of PZ-601 (SMP-601) and other β-lactams with chromosome- and plasmid-encoded class C β-lactamases

J.D. Docquier, L. Xerri (Siena, IT; Malvern, US)

Objectives: The overproduction of chromosome-encoded class C β-lactamases in derepressed mutants of Enterobacteriaceae and *Pseudomonas aeruginosa* is a known mechanism able to compromise the efficacy of penicillins and cephalosporins for the treatment of infections caused by these organisms. More recently, the emergence of plasmid-encoded class C β-lactamases, currently spreading in Enterobacteriaceae, is of increasing concern. We carried out a comparative study on the interaction of PZ-601 (a novel carbapenem with a spectrum including multidrug resistant Gram-positive pathogens) with several class C enzymes.
Methods: The stability of PZ-601, imipenem and cephalosporins to hydrolysis by P99 AmpC, CMY-2 and FOX-7 β-lactamases was investigated spectrophotometrically, using either direct hydrolysis measurements or the reporter substrate method. Antimicrobial susceptibilities of clinical isolates and transconjugants (or transformants) thereof were measured using the microdilution broth method as recommended by the CLSI.
Results: In enzyme assays, PZ-601 behaved as a poor substrate of these enzymes and, similarly to imipenem (IPM), showed degradation rates slower than those observed with tested oxyimino-cephalosporins cefotaxime (CTX) and ceftazidime (CAZ), and piperacillin (PIP), as reflected by the higher catalytic efficiencies measured with the latter compounds. These data were confirmed by the changes in the antimicrobial susceptibility profiles when a CMY-2-encoding plasmid was transferred into an *E. coli* laboratory strain (J53). This transformed

strain gained resistance to CAZ, CTX and PIP, while it showed only a reduced susceptibility to PZ-601.

Strain	β-lactamase	MICs (mg/L)				
		PZ-601	IPM	CAZ	CTX	PIP
E. coli J53	None	0.25	0.12	0.12	0.06	1
E. coli J53 (p26Sm02)	CMY-2	2	0.12	64	16	>512
E. coli 26Sm02	CMY-2	4	0.25	64	32	>512
Enterobacter cloacae RM-SI	AmpC	8	0.5	64	64	32
Klebsiella pneumoniae Kpn7	FOX-7	8	0.25	256	32	>512

The parental clinical isolates all exhibit the lower MIC values with IPM and PZ-601, while a high level of resistance was observed with the other agents. It is likely that for PZ-601, permeability defects in these isolates may act synergistically with a slow β-lactamase degradation, explaining in part the different susceptibility to the latter, as compared to IPM.
Conclusion: PZ-601 was confirmed to have a better stability to class C β-lactamases than tested oxyimino-cephalosporins and penicillins, even though it appeared to be slightly less stable to these enzymes than imipenem.

P566 Stability of PZ-601 (SMP-601) to different clinically relevant extended-spectrum β-lactamases

J.D. Docquier, L. Xerri (Siena, IT; Malvern, US)

Objectives: PZ-601 is a new carbapenem showing activity against meticillin-resistant *Staphylococcus aureus* and vancomycin-resistant enterococci. PZ-601 has been shown to exhibit good activity versus Gram-negative pathogens producing extended-spectrum β-lactamases (ESBLs) (Paterson et al.; Lolans et al., ICAAC 2007). The stability of PZ-601 to various clinically-relevant enzymes is investigated and compared to that of other β-lactams.
Methods: The stability of PZ-601 to the hydrolytic action of representative TEM-, SHV-, CTX-M- and GES-types ESBLs was investigated spectrophotometrically, using either direct hydrolysis measurements or the reporter substrate method. In the latter case, inactivation parameters were computed from enzyme inactivation time courses in the presence of various carbapenem concentrations. Susceptibilities to PZ-601, imipenem (IPM), ceftazidime (CAZ), cefepime (FEP) and piperacillin (PIP) were measured (microdilution broth method, CLSI) for recombinant strains carrying the cloned β-lactamase gene and clinical isolates with known β-lactamase content.
Results: In enzyme assays, PZ-601 behaved as a transient inactivator of all tested β-lactamases. It showed an excellent stability to these enzymes, as reflected by extremely low deacylation rates. Interestingly, PZ-601 was more stable than IPM to GES-1, behaving as a poor substrate of this enzyme. MIC values of PZ-601 were not affected by β-lactamase production in laboratory strains of *E. coli* expressing the cloned β-lactamase gene, in comparison with the control strain carrying the empty cloning vector.

Strain	ESBL	MICs (mg/L)				
		PZ-601	IPM	CAZ	FEP	PIP
E. coli DH5α(pBC-SK)	None	0.25	0.12	0.12	0.06	1
E. coli DH5α(pLBII-TEM-72)	TEM-72	0.25	0.12	64	4	512
E. coli DH5α(pLBII-SHV-12)	SHV-12	0.25	0.25	256	8	256
E. coli DH5α(pLBII-CTX-M-1)	CTX-M-1	0.25	0.25	1	4	64
E. coli DH5α(pBC-GES-1)	GES-1	0.25	0.5	2	0.12	64

The determination of the antimicrobial susceptibility profiles of the clinical isolates producing the same ESBLs revealed an in vitro efficacy of PZ-601 similar to that of IPM, while higher MIC values were expectedly recorded for third- and fourth-generation cephalosporins and penicillins.
Conclusion: Due to its stability to most types of clinically-relevant ESBLs, PZ-601 is active on both ESBL-producing laboratory strains and their parental clinical isolates. PZ-601 might represent a valuable alternative drug for empiric therapy when broad-spectrum antimicrobial activity, including both multidrug-resistant Gram-positives and Gram-negatives, is required.

P567 New thioureides of 2-(4-methyl-phenoxymethyl) benzoic acid with antimicrobial activity

C. Limban, G.M. Nitulescu, C.D. Badiceanu, O. Dracea, I. Raut, C. Larion, A.M. Israil, M.C. Chifiriuc (Bucharest, RO)

Objectives: The present application is a continuation of our research concerning the synthesis and characterisation of 2-(4-methyl-phenoxymethyl)-benzoic acid thioureides with antimicrobial activities.
The aim of this study was to evaluate the in vitro antimicrobial activity of some newly synthesised chemical compounds using qualitative and quantitative methods.
Methods: The new thioureides were obtained in three stages: first, the 2-(4-methyl-phenoxymethyl)benzoic acid by reacting sodium p-methyl-phenoxide with phtalide, then the synthesis of the 2-(4-methyl-phenoxymethyl)benzoic acid chloride, and finally the corresponding isothiocyanate is treated with primary aromatic amines to obtain the new compounds.
The qualitative screening of the susceptibility spectra of different microbial strains to these compounds was performed by three adaptated diffusion methods: paper filter disk impregnation with the tested substances solutions, the disposal of tested solutions in agar wells and the spotting of tested solutions on solid medium seeded with microbial inoculums. The quantitative assay of the antimicrobial activity was performed by broth microdilution method in 96-well microplates in order to establish the minimal inhibitory concentration (MIC).The antimicrobial activity was tested against Gram-positive strains (*Staphylococcus* (*S.*) *aureus*, *Bacillus* (*B.*) *subtilis*), Gram-negative (*Escherichia* (*E.*) *coli*, *Pseudomonas* (*P.*) *aeruginosa*, *Klebsiella* (*K.*) *pneumoniae*) and fungal strains (*Candida* (*C.*) *albicans*, *Aspergillus* (*A.*) *niger*). All tests were performed comparatively with reference strains: *K. pneumoniae* IC 13420, *E. coli* IC 13529, *S. aureus* IC 13204, *P. aeruginosa* IC 13202, *B. subtilis* IC 12488, *C. albicans* IC 249, *A. niger* IC 13534.
Results: Chemical structures of the synthesised compounds have been elucidated by theirs 1H-NMR, 13C-NMR, IR spectra and elemental analysis.
Our results showed that the tested compounds exhibited specific antimicrobial activity, the highest activity being noticed against suspended fungal cells (MIC ranging from 62.5 to 15.6), followed by *P. aeruginosa* (MICs from 250 to 31.5). Antimicrobial activity against Gram-positive bacteria were noticed for most compounds exhibiting very low MICs (MICs from 1000 to 62.5).
Conclusion: The 2-(4-methyl-phenoxymethyl)-benzoic acid thioureides exhibited specific antimicrobial activity and may be regarded as potential antimicrobial agents.

P568 A synthetic derivative of the host immune defence peptide, bactenecin, activity against clinical isolates of meticillin-susceptible and meticillin-resistant *Staphylococcus aureus*, a potential new therapeutic agent

E. Williams, S. Desgranges, M. Devocelle, H. Humphreys, D. Hughes (Dublin, IE)

Vancomycin is one of the few antibiotics still effective in the treatment of meticillin-resistant *Staphylococcus aureus* (MRSA) and treatment failures are increasingly reported with this antibiotic. Therefore, the development of alternative antibiotics with novel modes of action is critical. Cationic antimicrobial peptides with structures resembling naturally occurring host defence peptides are promising candidates. Some of the benefits of host defence peptides as antimicrobial agents

include, reduced capacity to develop resistance, multiple and novel modes of action and reduced toxicity.
Objectives: In this study, the potential of an 8 amino-acid linear peptide derived from bactenecin, an immune peptide found in bovine neutrophils, as a therapeutic agent for the treatment of MRSA, was investigated.
Methods: The minimum inhibitory concentrations (MIC) of D and L-stereoisomers of the bactenecin derived peptide, for thirteen MRSA and twelve meticillin-susceptible *S. aureus* (MSSA) isolates from bloodstream infections were determined. The effect of pH, salt concentration and cations, calcium and magnesium, on the in-vitro activity of the peptide was also investigated. The capacity for development of in-vitro resistance to the bactenecin derived peptide was also studied by sequential exposure of two MRSA isolates to the L-peptide, and comparison of the MIC of surviving colonies to the parental colonies.
Results: All isolates were susceptible to the bactenecin-derived peptide with MIC $\leqslant$ 50 μg/ml for the L-peptide and MIC $\leqslant$ 5 μg/ml for the D-peptide. Optimal bactericidal activity was reached over the pH range 7.0 to 9.0 and potassium phosphate concentration of 1–10 mM. The MIC was not affected by calcium and magnesium. Sequential exposure of two clinical isolates, seven times to a sub-inhibitory concentration of the L-peptide, did not change the MIC, suggesting that further exposure would be required to generate resistance.
Conclusions: Our study concludes that this bactenecin-derived peptide may have potential for development as an alternative anti-staphylococcal agent, as it is effective against invasive isolates of MSSA and MRSA, is active under physiological conditions and does not easily select resistant mutants.

P569 In vitro activity of a cecropin A-melittin antimicrobial peptide hybrid vs. multidrug-resistant strains of *Acinetobacter baumannii* prevalent in the UK

D. Wareham, P. Khanna, W. Kamysz (London, UK; Gdansk, PL)

Objectives: *Acinetobacter baumannii* has emerged as an important nosocomial pathogen causing burn wound infections, ventilator associated pneumonia, bacteraemia and sepsis in the critically ill. The organism exhibits formidable multi-drug resistance with the commonest isolates in the UK (OXA-23 clone 1) exhibiting resistance to all β-lactams (including carbapenems), β-lactam / inhibitor combinations, quinolones, and aminoglycosides. In view of the lack of agents in development for the treatment of MDR *Acinetobacter*s we set out to determine the in-vitro activity of a hybrid of two antimicrobial peptides, cecropin A and melittin (CAMEL) versus a collection of recent clinical isolates and determine the killing kinetics versus the OXA-23 (1) strain.
Methods: A 15 residue peptide based on residues 1–7 of cecropin A and residues 2–9 of melittin was synthesised using fmoc chemistryand purified by solid phase extraction. Sixty-six consecutive clinical isolates, identified as *A. baumannii* by API 20NE and confirmed by specific PCR for the OXA-51 gene were obtained. Inhibitory and bactericidal concentrations of CAMEL peptide were determined by microtitre dilution using according to standard BSAC methodology. Time-kill assays using Camel peptide at 1 X and 2 X the MIC were performed on a representative isolate of OXA-23 clone 1.
Results: The MIC50 of Camel peptide was 8 mg/L and the MIC90 16 mg/L with a range of 4–32 mg/L. The MBC50 and MBC90 were 16 and 32 mg/L respectively (range 8–64 mg/L). In time kill assays Camel was rapidly bactericidal within 2 hrs. At 2 × MIC >3-fold log reductions in CFU/ml were sustained over 24 hrs.
Conclusions: CAMEL peptide exhibited promising activity versus prevalent strains of multidrug resistant *A. baumannii* and was rapidly bactericidal versus the OXA-23 clone 1 of *A. baumannii*. Further studies to determine in vivo stability, bioavailability and toxicity towards eukaryotic cells are needed to enable further development of this novel compound.

P570 Resistance studies on the siderophore monobactam/β-lactamase inhibitor combination BAL30376

B. Hofer (Basel, CH)

Objective: Multi-resistant clinical isolates of Gram-negative bacteria were examined for their propensity to develop resistance to BAL30376, novel combination between the monobactam antibiotic BAL0019764 and the specific β-lactamase inhibitors BAL0029880 and clavulanic acid.
Methods: Isolates of *Pseudomonas aeruginosa*, *Acinetobacter* sp., *Stenotrophomonas maltophilia*, *Enterobacter cloacae*, and *Klebsiella pneumoniae* were examined for their propensity to spontaneously acquire resistance to BAL30376 and selected comparators, either in single-step selection or by repeated passaging in cultures with increasing concentrations of BAL30376.
Results: Population analysis indicated single-step resistance frequencies of 10^{-8} to 10^{-10} for BAL30376 against the strains Enterobacteriaceae and *Acinetobacter*. The frequency of appearance of spontaneous resistance to cefepime or meropenem in susceptible strains was between 10^{-6} and 10^{-9}. Subpopulations with elevated BAL30376 MICs (up to 8 mg/L) were identified in all *P. aeruginosa* strains examined, with incidence between 10^{-7} and 10^{-9}. Subpopulations resistant to cefepime or meropenem were also detected at an incidence between 10^{-5} and 10^{-7}. Repeated passaging in cultures containing BAL30376 yielded strains with >4-fold elevated MIC after 10–20 passages. Strains with >4-fold elevated MIC towards cefepime or meropenem appeared within 4 passages under the same conditions. Many of the resistant isolates obtained in these studies had increased levels of expression of β-lactamase.
Conclusion: Low frequencies of spontaneous resistance to BAL30376 were observed. Despite its complexity, the triple combination is relatively refractory to development of resistance.

P571 Bactericidal effect of the siderophore monobactam/β-lactamase inhibitor combination BAL30376

C. Geier (Basel, CH)

Objective: BAL30376 is a novel combination between the monobactam antibiotic BAL0019764 and the specific β-lactamase inhibitors BAL0029880 and clavulanic acid. We have assessed the in vitro time-kill kinetics of this combination using a selection of multi-resistant Gram-negative bacteria.
Methods: MICs were determined by standard broth micro-dilution methods. A preliminary MBC was determined by plating out the clear wells from the MIC determination and counting colonies 24 and 48h after plating. Time-kill studies were done in standard growth medium with an inoculum of approximately 10^6 cfu/ml. Serial dilutions were taken a 0, 3, 6, 24 and 28 h after inoculation.
Results: MBC was 1–4 × MIC for the action of BAL30376 against most strains of Enterobacteriaceae and *Acinetobacter* sp. that were investigated. MBC could be up to 16 × MIC for the action of BAL30376 against some strains of *Pseudomonas aeruginosa*. Against the same strains, the MBCs of cefepime and meropenem were 1–4 × MIC for susceptible strains of Enterobacteriaceae and 4–>32 × MIC for susceptible strains of *Acinetobacter* and *P. aeruginosa*. Time-kill analysis demonstrated that BAL30376 decreased the cfu count by 3 orders of magnitude within 24 h at 4 and 8 × MIC against Enterobacteriaceae, *Acinetobacter* and *P. aeruginosa*. The kill kinetics were dependent on inoculum density and were faster with an inoculum of 5×10^4 cfu/ml and slower with an inoculum of 10^7 cfu/ml.
Conclusion: BAL30376 has marked bactericidal activity against a range of multi-resistant Gram-negative bacteria, including carbapenem-resistant strains.

P572 In vivo effectiveness and dose response of BAL30376 in murine peritonitis sepsis model caused by *Pseudomonas aeruginosa* or by extended-spectrum β-lactamase producing *Escherichia coli*

S. Navon-Venezia, M. Page, A. Schmitt-Hoffmann, Y. Carmeli (Tel Aviv, IL; Basel, CH)

Pseudomonas aeruginosa (PA) and extended spectrum beta lactamase (ESBL) *E. coli* are common nosocomial pathogens often affecting immunocompromised patients that are difficult to treat. Against these pathogens we aimed to study in a lethal mice peritonitis sepsis model of infection the in vivo efficacy of a new monobactam beta lactamase inhibitor combination, BAL30376 specifically designed to overcome most resistance mechanisms in non-fermenters and Enterobacteriaceae, including metallo betalactamases and ESBLs.

Methods: PA and ESBL *E. coli* with MIC <0.0625 mg/L for BAL30376 were used as infecting bacteria in the in vivo model. Neutropenia was induced in ICR mice (23–25 g) and peritonitis was induced by intraperitoneal inoculation of either PA or ESBL *E. coli*. Efficacy was studied at various bacterial inocula: 5×10^2 -1×10^4 cfu /mouse (1–50 LD50) for PA, and $4–8\times10^6$ cfu /mouse (4–8 LD50) for ESBL *E. coli*. Mice (n = 12) were treated with BAL30376 three times a day given ip for three days. Dose effect was studied at a range of doses between 6.25 to 100 mg/Kg. Survival was monitored for seven days post infection and compared with control groups (A saline placebo group and a meropenem treated group) using log rank test.

Results: In two sets of experiments PA peritonitis (at 6x LD50) resulted in 70–100% mortality in placebo group. BAL30376 had 100% protection at doses $\geqslant$ 25 mg/Kg ($p<0.01$) similarly to the meropenem treated group. Lower doses of BAL30376 were moderately protective. ESBL *E. coli* peritonitis was studied in two experiments (4–8x LD50) and resulted in 100% mortality in placebo group. BAL30376 had 100% protection at doses $\geqslant$ 12.5 mg/Kg ($p<0.01$). With both pathogen studied at various inocula and dosages of BAL30376 dose effect were confirmed.

Conclusions: BAL30376 was highly effective in treating lethal peritonitis and sepsis caused by PA or ESBL *E. coli* in murine model.

P573 Comparative efficacy of EDP-420, azithromycin, telithromycin, clindamycin, trimethoprim/sulfamethoxazole, linezolid and levofloxacin against murine skin abscess induced by meticillin-resistant *Staphylococcus aureus* USA300 PVL+ mecA strain

X. Luo, R. Wu, M. Wang, L.J. Jiang, D. Wachtel, A. Polemeropoulos, L.T. Phan, G. Wang, Y.S. Or (Watertown, US)

Objectives: USA 300, a pulsed-field type of meticillin-resistant *Staphylococcus aureus* (MRSA) isolates, has demonstrated in outbreak and non-outbreak community-acquired (CA-MRSA) as well as hospital-associated *S. aureus* skin and soft-tissue infections (SSTI) which is becoming one of the biggest infectious mysteries of the decade. Investigators are not sure where it came from, where it lives, how it spreads and how to treat empirically. USA 300 had an antimicrobial susceptibility profile demonstrating resistance only to β-lactams and erythromycin while retaining susceptibility to clindamycin, levofloxacin, trimethoprim–sulfamethoxazole, and vancomycin. Guidelines for the empirical treatment of CA-MRSA on SSTI are ambiguous. EDP-420, a new bicyclolide (bridged bicyclic macrolide) with unique structural features, was sensitive against USA300 in vitro. It is necessary to compare its in vivo efficacy with major antibiotics in murine skin abscess model induced by USA300 and to determine its skin and abscess concentration (a tissue PK).

Methods: Skin abscess was induced in mice by subcutaneous inoculation of 10^7 CFU of USA300. Mice developed abscess within 1 day. Abscess bacterial counts increased progressively. Bacterial counts can reach 10^9 CFU/g skin abscess tissue if leave untreated. Treatment was initiated immediately, 24 h and 48 h after inoculation. Bacterial burden in abscess and lesion sizes were compared by the end of the experiments. Single dose pharmacokinetics of EDP-420 in plasma, normal skin and abscess tissue were compared in abscess infected mice.

Results: EDP-420 was as effective as linezolid and clindamycin in the MRSA (*S. aureus* USA300) model of murine abscess with a PD50s of 5.3, 7.3 and 10.7 mg/kg respectively. Levofloxacin and telithromycin were less active than EDP-420 with a PD50s of 20.1 and 25.9 mg/kg respectively. Azithromycin and trimethoprim/sulfamethoxazole performed poorly with a PD50s of >100 mg/kg. EDP-420 exhibited an 8 fold abscess/plasma AUC ratio. Abscess in untreated animals appeared 24 h after inoculation, and persisted for up to 2 weeks.

Conclusion: EDP-420 demonstrated better efficacy in the CA-MRSA murine abscess model in comparison with currently marketed oxazolidinone, lincosamide, fluoroquinolone, ketolide, macrolide as well as dihydrofolate reductase inhibitor/sulfonamide class antibiotics. The results indicate that EDP-420 is potentially a potent antibiotic for treatment of CA-MRSA in SSTI.

P574 Comparative effects of faropenem-medoxomil and amoxicillin-clavulanate on the normal oral and intestinal micro flora and the selection of penem-resistance

M. Koch, W. Heizmann, J. Nagelschmitz, A. Dalhoff (Kiel, DE)

Objectives: Community-acquired enterobacteriaceae have acquired ESBL- or AmpC-producing genes thus requiring more active β-lactams such as faropenem. However suppression of the normal flora in the oral cavity and gastro-intestinal tract may select for colonisation with resistant bacteria. Therefore we evaluated the effects of orally administered faropenem-medoxomil (FAR) or amoxicillin-clavulanate (A/C) on the normal human flora and on colonisation of the oral cavity and colon. Emergence of penem-resistance was monitored.

Methods: Healthy male volunteers were dosed orally for 8 days with 300mg FAR or 875/125mg A/C, bid. Oropharyngeal swabs and faeces were collected prior to the 1st dose, and then on 1, 7, and 14 days after dosing. Species representing the oral/faecal flora were sought including *Streptococcus* spp., Lactobacilli, Enterobacteriaceae, Peptostreptococci, enterococci, *Bacteroides* spp., and *Clostridium* spp.. *Clostridium difficile* toxin A + B was analysed by EIA. Colonisation with *Candida albicans*/*krusei* was monitored. Emergence of penem-resistance was screened by using media containing 2, 4, 8mg FAR and 4, 16mg meropenem.

Results: No significant changes in the oropharyngeal flora were seen either in the FAR or the A/C groups. Transient increases in faecal enterococci were seen in both groups, and in *E. coli* in only the A/C group. Counts of *B. fragilis* spp. tended to decrease in both groups. *C. difficile* was not isolated nor toxin detected from any subject. No colonisation with *Candida* spp. was found. Transiently, *P. aeruginosa* was isolated only on day 1, but not 7 + 14d after exposure to FAR (n = 2) or A/C (n = 1). No penem-resistant Enterobacteriaceae were isolated, but in each of 3 volunteers penem-resistant *E. faecalis* were isolated but which disappeared on day 14.

Conclusion: 8 day exposure to FAR resulted in no changes in the oropharyngeal and minimal changes in the faecal flora. *C. difficile* was not selected and overgrowth with *Candida* spp. was not detected. Penem-resistance did not emerge. Thus, FAR does not seem to cause major changes in the resident oro-pharyngeal or faecal flora or lead to the emergence of penem-resistance.

P575 Tifacogin, a recombinant tissue factor pathway inhibitor eliminates serum-resistant *Escherichia coli* from blood cultures

S. Schirm, X. Liu, L. Jennings, P. Jedrzejewski, Y. Dai, S. Hardy (Emeryville, US)

Objectives: Tifacogin – tissue factor pathway inhibitor (rTFPI), has demonstrated therapeutic effectiveness in acute inflammatory disease after lethal challenge with *Escherichia coli* in several animal models of severe sepsis. Tifacogin is being evaluated in a phase 3 clinical trial in patients with severe community acquired pneumonia. The mechanism of action of tifacogin after acute bacterial infection is not well understood.

Our current study investigates the effects of tifacogin after acute infection in vitro. The objectives were to show whether fragmented tifacogin had antibacterial activity against *E. coli* which could be mapped to the C-terminus and to investigate the effect of heparin on the antibacterial activity of fragmented tifacogin.
Methods: 10% donor derived blood or serum were used to culture 3 strains of serum resistant *E. coli* for 4 hours at 37ºC with varied concentrations of fragmented tifacogin prepared using plasma proteases or synthetic C-terminal peptides. Bacterial survival was assessed by plating serial dilutions of the reaction mixes onto tryptase soy agar plates. Colony numbers were determined after overnight incubation at 37ºC. Direct interaction between TFPI peptides and *E. coli* was investigated by fluorescent microscopy using fixed bacteria and fluorescently labeled peptides. Heparin was included in some cultures or binding experiments.
Results: C-terminal tifacogin fragments and synthetic peptides exhibited antibacterial activity in a complement-dependent fashion. While intact tifacogin slightly enhanced *E. coli* growth, tifacogin digested with plasma proteases dramatically reduced growth. The activity was mapped to a highly positively charged region previously identified within intact TFPI as a heparin binding site. Synthetic peptides including the positive region were highly active (MIC90 10–30nM). Antibacterial action involved the classical complement pathway including terminal complex formation since factors C1q, C2, C3, C4, C5, C6 and C9 were required. Direct interaction with the bacterial cell surface of *E. coli* was seen. Complement mediated killing and cell surface binding were reversed by low amounts of heparin.
Conclusions: Our results show a novel activity of the C-terminus of tifacogin in complement resistant *E. coli* infection that is released by fragmentation of tifacogin. As tifacogin is rapidly degraded in vivo, our findings suggest that tifacogin may have a therapeutic role in management of disease caused by acute infection.

P576 Highlights on the mode of action of ST-246, an anti-orthopoxviral compound

S. Duraffour, S. Vigne, K. Vermeire, J.M. Crance, D. Garin, R. Jordan, D.E. Hruby, G. Yang, G. Andrei, R. Snoeck (Leuven, BE; Grenoble, FR; Corvallis, US)

Objectives: ST-246 is a highly potent and orally bioavailable anti-orthopoxviral molecule that targets the F13L protein of vaccinia virus (VACV). We investigated part of its mechanism of action by using small interfering RNAs, i.e., siF13Ls, designed to specifically knockdown the F13L gene and by characterising ST-246 resistant strains of VACV and camelpox virus (CMLV).
Methods: The VACV strains Copenhagen, Western Reserve (WR) expressing GFP as a C-terminal fusion protein with F13L or an F13L deleted virus expressing GFP from the F13L locus, and the Iran CMLV strain were used. Cultures of human embryonic lung fibroblasts (HEL) were transfected with the siF13L of interest, and infected 24h later at a MOI of 0.01. The effects of siRNA were determined by real-time RT-PCR, viral titrations and flow cytometry. For the selection of resistant viruses, VACV and CMLV were propagated in HEL cells under increasing concentrations of ST-246 for approximately 17 passages. Strains exhibiting at least 100-fold increase of their wild type 50% inhibitory concentration (IC50) were defined as resistant.
Results: Real-time RT-PCR and viral titrations data indicated that siF13Ls (100 nM) knocked down the VACV and CMLV F13L gene transcripts by more than 85% and reduced their replication by 90%. At lower siF13L concentrations, VACV and CMLV replication was inhibited in a different way, which is in agreement with our previously published data on the anti-VACV and -CMLV activity of ST-246. Flow cytometry analysis showed a reduction of VACV-WR replication expressing a F13L-GFP, but not of a F13L deleted VACV-WR, by siF13Ls and ST-246 and validated a common target, i.e., F13L. Furthermore, the IC50 values of two ST-246 resistant CMLV mutants were >20 μg/ml compared to 0.005 μg/ml for the wild type. In the case of VACV, a 120-fold increase of the IC50 value indicated a ST-246 resistant phenotype. Sequencing of the F13L genes, for both resistant and wild type VACV and CMLV strains, is currently ongoing.
Conclusion: We have shown the inhibitory potency of siF13L inducing a specific silencing of the F13L gene which resulted in the inhibition of VACV and CMLV yields. We demonstrated the mode of action of ST-246 at the protein level and not on mRNA. A single target for ST-246 has been validated in VACV and CMLV. We also isolated ST-246 resistant clones of both viruses and the determination of mutations induced by ST-246 in the F13L gene is currently investigated.

P577 REP3123, a novel inhibitor of methionyl tRNA synthetase from *C. difficile*

I. Critchley, T. Jarvis, J. Guiles, X. Sun, R. Evans, D. Davies, L. Green, U. Ochsner, C. Young, D. Citron, S. Bell, D. Drolet, S. Gill, N. Janjic (Louisville, Bainbridge Island, Culver City, US)

Objectives: *C. difficile*-associated disease (CDAD) is caused by overgrowth of toxin-producing strains of *C. difficile* (CD) following disruption of normal gut flora. Currently, there are few therapeutic options and clinical problems are associated with disease recurrence and the persistence of spores in the environment. In this report, we describe biochemical, crystallographic, microbiological and in vivo efficacy properties of REP3123, a novel diaryldiamine inhibitor of CD methionyl tRNA synthetase (MetRS).
Methods: REP3123 was synthesised and purified as a single active enantiomer. CD MetRS was expressed in *E. coli* and purified to homogeneity. The enzyme was crystallised by sitting drop vapor diffusion and structures were solved by molecular replacement. Microbiological testing was done according to CLSI guidelines. Toxins A and B were detected by semi-quantitative immunoassays, Western blot and cytotoxicity assays. In vivo efficacy of REP3123 was evaluated in the hamster model of CDAD.
Results: The tight binding of REP3123 to MetRS (Ki=20 pM) is competitive with methionine but cooperative with ATP. Inhibitor binding is accompanied with a conformational change in the enzyme in which the inhibitor occupies the methionine binding pocket and a newly created hydrophobic pocket. REP3123 is highly active against CD, including the NAP1/027 outbreak strain (MIC range, 0.25–1.0 mg/L). In contrast, REP3123 is inactive against Gram-negative bacteria and many anaerobic bacteria that constitute normal gut flora such as *Actinomyces*, *Bacteroides*, *Bifidobacterium* and *Lactobacillus* species. As a protein synthesis inhibitor, REP3123 inhibits the production of CD toxins A and B under a variety of culture conditions. REP3123 is also highly effective in inhibiting spore formation. In vivo, REP3123 exhibits low oral bioavailability and superior efficacy to vancomycin in the hamster model of CDAD.
Conclusion: REP3123 is a novel mechanism-of-action antibacterial agent that exhibits potent and selective inhibition of CD with limited potential for disruption of normal gut flora. REP3123 effectively inhibits toxin production and sporulation, exhibits low oral bioavailability and protects against CDAD in vivo. With these unique features, REP3123 represents a promising new development candidate for the treatment of CDAD.

P578 Antimicrobial activity of ceftobiprole tested against leading European bacterial pathogens: results from an international surveillance programme (2005–2006)

T. Fritsche, H. Sader, M. Janechek, R. Jones (North Liberty, US)

Objectives: To evaluate potency of ceftobiprole (BPR) against the most serious and commonly occurring Gram-positive and -negative pathogens isolated in Europe. BPR, an investigational parenteral cephalosporin, is currently under regulatory review following completion of Phase III clinical trials. This agent is uniquely active against oxacillin-resistant (OXA-R) *S. aureus* (MRSA), as well as other Gram-positive and -negative pathogens, making it an attractive candidate for broad-spectrum therapy.

Methods: Consecutive, non-duplicate isolates (17,206) from bloodstream, skin and skin structure and respiratory tract infections were collected from medical centres in Europe (23), Turkey (2) and Israel (1) participating in the BPR Surveillance Program during 2005–2006. Identifications were confirmed by the central monitoring laboratory and all isolates were susceptibility (S) tested using CLSI methods against BPR and comparator agents.

Results: Results are in the Table. Among SA (27% OXA-R) and CoNS (75% OXA-R) isolates tested, BPR inhibited 100% at ⩽4 and ⩽8 mg/L, respectively. While BPR MIC90 values for OXA-R strains were elevated over those of OXA-S strains (8-fold), MIC90 values for other cephalosporins correspondingly increased ⩾32-fold. BPR was 4-fold more potent when testing beta-haemolytic streptococci (BHS) and SPN compared with CRO or FEP; all BHS were inhibited at ⩽0.25 mg/L and >99% of SPN by 0.5 mg/L. BPR was similar in potency to CAZ and FEP (MIC50 values, ⩽1 mg/L) against tested Enterobacteriaceae; coverage against EC was nearly identical for the three agents (94–95% inhibited at ⩽4 mg/L). FEP provided enhanced coverage against KSP (90% at ⩽8 mg/L vs. 78–84% for BPR and CAZ), although BPR and FEP had lower MIC values than CAZ against ESP. Cephalosporins were largely inactive against ESBL-producing EC and KSP. BPR was equal in potency to CAZ (MIC50, 2 mg/L) against PSA and two-fold more potent than FEP, although % inhibited for these agents at ⩽2/4/8 mg/L were similar. None of these agents inhibited >49% of ASP at 8 mg/L.

Species (no. tested)	MIC_{90} (% at ⩽2/4/8 mg/L)		
	BPR	CRO[a] or CAZ[b]	FEP
S. aureus (SA; 4,028)	1 (>99/100/–)	>32 (39/72/75)[a]	>16 (66/76/81)
Coagulase-negative staphylococcus (CoNS; 1,840)	2 (93/>99/100)	>32 (22/33/47)[a]	>16 (41/62/77)
S. pneumoniae (SPN; 1,528)	0.25 (100/–/–)	1 (>99/>99/100)[a]	1 (>99/>99/>99)
E. coli (EC; 2,779)	0.12 (93/94/94)	⩽1 (93/94/95)[b]	0.25 (94/95/96)
Klebsiella spp. (KSP; 883)	>8 (77/78/78)	>16 (80/81/84)[b]	16 (84/87/90)
Enterobacter spp. (ESP; 571)	>8 (81/84/87)	>16 (66/68/70)[b]	4 (88/92/96)
P. aeruginosa (PSA; 984)	>8 (54/65/79)	>16 (56/69/76)[b]	16 (49/66/80)
Acinetobacter spp. (ASP; 320)	>8 (41/41/42)	>16 (15/32/39)[b]	>16 (26/37/49)

Conclusions: BPR displays prominent activity against European staphylococci, including OXA-R strains. The compound also displayed activity against Enterobacteriaceae, similar to that of extended-spectrum cephalosporins, as well as against some non-fermentative bacilli. Given the breadth of its spectrum, BPR may be useful in those European institutions/ regions where MRSA and PSA are both prevalent.

P579 Antimycobacterial activity of two *Berberis* species used as traditional medicine in Iran

F. Khadem, H. Zare Maivan, H. Movassagh, M. Salimi, M. Sharifi, T. Sohrabi, B. Yazdanpanah, M. Rostami Baroei, M. Abolhassani (Tehran, IR)

Objectives: Tuberculosis (TB) is the leading cause of mortality worldwide, infecting about 9 million people and killing approximately 2 million people annually. In recent years, emerging multiple drug resistance (MDR) has become a major threat, thus there is an urgent need to search natural products for developing new, effective and affordable anti-TB drugs. Berberidaceae, especially berberis species are well known medicinal plants and are used in traditional medicine, foods and dies in Iran. Chemical composition of Berberidaceae species show that their anti-inflammatory and anti-tuberculosis activity is mainly due to alkaloid constituents. This study was conducted to compare antimycobacterial activity of extracted alkaloids from root bark and fruit of *Berberis vulgaris* and *B. integgerima* from the natural flora of Khorasan ecological region.

Methods: Root bark and fruit from two species were collected, shade air dried, lyophilised and powdered. Chloroform extracts containing alkaloid fractions were obtained. Fresh solutions of each extract were dissolved in 2% DMSO. The Chloroform extracts were incorporated into the Lowenstein-Johnson medium after solidification with final concentrations of 500, 250, 125, 62.5 and 31 μg/ml. Bacterial suspension test was adjusted to 3×10^5 CFU per ml *Mycobacterium bovis* BCG (Strain 1173 P2, Institut Pasteur, Paris, France) and incubated in 37 degrees of Celsius for 21 days. The minimum inhibitory concentration (MIC) amounts were evaluated after 21, 28 and 35 days of incubation. *Mycobacterium bovis* BCG was cultured in presence and absence of reference drug (Kanamycin) as controls. All tests were carried out five times.

Results: All four root bark and fruit chloroform extracts showed significant ($P < 0.05$) MIC concentrations (31–500 μg/ml), therefore 31 μg/ml was considered to be the best MIC for all four extracts.

Conclusion: Medicinal plants are an important resource to find original active drugs or new therapeutic agents especially against TB. The results indicate that root bark and fruit of *Berberis vulgaris* and *B. integgerima* can be used as antimycobacterial agents because of their considerable MIC values. Our investigations show that these remarkable results are due to alkaloids such as berberine, palmatine, oxyacantine and jatrorrhizine. Further investigations are required to assess the activities of these compounds against MDR *M. tuberculosis*.

P580 Antistaphylococcal activity of semi-purified fractions from Eleutherine americana

S. Voravuthikunchai, B.O.T. Ifesan, W. Mahabusarakam, C. Hamtasin (Hatyai, Songkla, TH)

Introduction: Meticillin-resistant *Staphylococcus aureus* (MRSA) infections are a global health concern due to the severity of the illnesses they may cause, ranging from mild to very severe infections. The numbers of *S. aureus* strains that exhibit antimicrobial resistance properties have increased and there is a potential risk of transmitting antibiotic resistance genes to the human microbiota through foods. Interest in plants with antibacterial properties has revived as a consequence of current problems associated with the use of antibiotics. Preliminary research from our laboratory revealed that the crude extract from Eleutherine americana produced good antibacterial effect on *S. aureus* from foods. The aim of the present study was to examine the activity of semi-purified fractions from this plant extract against meticillin-resistant strains isolated from foods and enterotoxin-producing reference strains.

Methods: Twenty-two MRSA strains isolated from food together with two enterotoxin-producing strains (ATCC 23235 and ATCC 27664) were used in this study. The Minimum inhibitory concentration (MIC) was determined by the broth dilution method and Minimum bactericidal concentration (MBC) was performed with the extracts that gave significant MIC values using a sterile loop streaking on fresh MHA (CLSI standard methods). Time-kill assay in the presence of these fractions were carried out. The crude hexane extract was chromatographed on column chromatography and fractions were obtained on the basis of their TLC characteristics.

Results: Fraction Ea 6.3 had MIC90 of 0.25 mg/ml while Ea 9.0 gave MIC50 of 0.125 mg/ml with MBC values ranging from 0.25 ⩾ 1.00 mg/ml for the two fractions on all the strains tested. Kill-curve in the presence of Ea 6.3 at 4MIC resulted in total killing of the cells at 20 h for reference strains and 24h for MRSA while fraction Ea 9.0 reduced the inoculum size by 7 log cycle.

Conclusion: Both fractions were very effective against all food isolated MRSA as well as enterotoxin-producing strains. These semi-purified fractions are being investigated in our laboratory to provide alternate treatment against MRSA.

Fund (BRG 4880021, fiscal year 2005–2008).

P581 Approach to identify novel antimicrobials against staphylococci

I. Abaev, O. Korobova, E. Pecherskikh, P. Kopylov, N. Kiseleva, D. Donovan (Obolensk, RU; Beltsville, US)

Objectives: Bacteriophage endolysins degrade the host cell wall peptidoglycan with near-specie specificity, and thus are of interest as

antimicrobials against *Staphylococcus aureus*. Previous *S. aureus* phage endolysin studies have been based on organisms from Western Europe and North America. Our study extends this to phages from Russia. We have developed a screening system to identify novel phage endolysin proteins of *S. aureus*.
Methods and Results: Lytic bacteriophages have been selected from clinical and environmental samples, or by induction of prophages from a population of temperate bacteriophages from MRSA and MSSA strains. High titer phage lysates of lytic bacteriophage have been tested by nine PCRs to screen for *S. aureus* phages carrying endolysin genes from either five homologous groups (>90%) or four stand alone endolysin genes. This strategy should rule out known endolysin genes and thus identify putative novel genes that are not homologous to previously reported genes. Crude phage lysates harboring candidate novel endolysins are tested for their ability to kill live pathogenic staphylococci in both zymogram analysis and turbidity assays. In the zymogram analysis, selected phage lysates demonstrate two bands (53 kDa and 27 kDa) that are not present in control lysates. Eight phage-associated lysates from candidate novel endolysin harboring phages have demonstrated the ability to kill exponentially growing MRSA and MSSA. Positive isolates are subjected to shotgun cloning of phage DNA and some cloned inserts have been sequenced. Currently, the subcloned phage DNA fragments have no similarity to data deposited in public databases.
Conclusions: The proposed approach is showing promise for identifying novel endolysin genes. Our next focus will be to perform MALDI-TOF analysis on purified phage proteins known to harbor lytic activity in zymogram analysis.
Acknowledgements. This research is supported by ARS-ISTC #499/3571 Project Grant.

P582 Photodynamic therapy against resistant bacteria from cystic fibrosis patients

O. Torun, S. Ak, B. Sener (Ankara, TR)

Objectives: Photodynamic therapy (PDT) combines a photosensitizer dye with visible light to generate reactive oxygen radicals toxic to cells. High rate of antibiotic resistance in cystic fibrosis (CF) isolates highlights the need for new treatment strategies. This study is aimed to evaluate the in-vitro effect of PDT alone and in the presence of antibiotics on MRSA, *Pseudomonas aeruginosa* (PA), *Stenotrophomonas maltophilia* (SM) and *Burkholderia cepacia* complex (BCc) isolated from CF patients.
Methods: Four MRSA, 4 PA, 8 SM and 2 BCc isolates were initially tested for susceptibility by microdilution method. PDT was applied by using toluidine blue at a light dose of 54 J/cm^2 with a light emitting diode on microtiter plates and killing was determined by viable cell counts. PDT was also applied on antibiotic containing MIC trays and effect on MIC values were tested. MBC values were determined by direct plate count for MIC and MIC+PDT trays.
Results: All PA, Sm and Bcc strains were resistant to ceftazidim (CAZ), meropenem (MEM), ciprofloxacin (CIP) and amikacin (AK), except for two PA strains susceptible to AK and CIP. All MRSA strains were also resistant to AK and CIP. Overall PDT alone exhibited 4 log killing in 8, 2 log in 4, 1 log in 5 and no effect in one strain. PDT application in presence of antibiotics lowered the MIC values in all bacteria except for two PA strains, at least for 4 folds for all the antibiotics tested to susceptible levels. PDT application in the presence of antibiotics decreased viable cell counts at least 3 logs for all the MRSA, SM, BCc strains. PDT+CAZ and PDT+MEM achieved no bactericidal activity in 3 PA strains while AK and CIP exhibited bactericidal activity in the presence of PDT for all PA strains.
Conclusions: Although PDT alone was not able to achieve bactericidal activity for all the tested strains, a significant bactericidal effect was detected when PDT was applied in the presence of antibiotics for all bacteria except for PA. Resistance to antibiotics in CF isolates may be overcome by the synergistic activity of PDT which should further be improved for in-vivo application.

In vitro actibacterial susceptibility studies

P583 Enhanced activity of daptomycin and vancomycin combined with imipenem or oxacillin against community-acquired MRSA isolates

R. Jones, P. Rhomberg, R. Fritsche, H. Sader (North Liberty, US)

Objectives: To study glycopeptides and lipopeptides in combination with potent antistaphylococcal β-lactams against community-acquired MRSA (CA-MRSA). CA-MRSA has emerged as a serious clinical therapeutic problem because of limited orally administered treatment options, recognised virulence (Panton-Valentine leukocidin) and ubiquitous presentations in outpatient practice in the USA and worldwide. Serious invasive cases needing hospitalisation require prompt selection of bactericidal, parenteral agents. We report drug combinations with enhanced killing activity.
Methods: Following CLSI susceptibility (S) test screening of >100 CA-MRSA, vancomycin (MIC50, 1 mg/L), daptomycin (MIC50, 0.25 mg/L) and imipenem (IPM; MIC50, 0.5 mg/L) each had potential treatment utility as well as oxacillin (OXA; MIC50, 16 mg/L) in combination. Ten strains with USA300 PFGE patterns (three USA300–0114) or variations were selected for checkerboard synergy/interaction tests. Interpretations used FICA calculations. The control β-lactam was OXA and internal organism control was *S. aureus* ATCC 29213 (MSSA).
Results: All drugs tested alone were consistent with expected results for a MRSA except IPM where contemporary USA300 CA-MRSA MIC values ranged from only 0.03 to 2 mg/L (S levels by CLSI and US-FDA breakpoints). Combinations of IPM with daptomycin and vancomycin clearly indicated enhanced inhibition (and killing; data not shown) for 9–10 of 10 strains (synergy [SYN] or partial SYN [PSYN]). Similarly, OXA with daptomycin or vancomycin demonstrated SYN or PSYN at concentrations easily achievable in vivo. The control MSSA strain interaction results varied from indifference (daptomycin or vancomycin) to PSYN (daptomycin/OXA).

Combination[a]	Interaction category (occurrences):				
	Synergy	Partial synergy	Additive	Indifferent	Antagonism
DAP/OXA	6	4	0	0	0
DAP/IPM	4	6	0	0	0
VAN/OXA	1	9	0	0	0
VAN/IPM	9	0	0	1	0

[a]DAP = daptomycin, OXA = oxacillin, IPM = imipenem and VAN = vancomycin.

Conclusions: Carbapenem (IPM) MIC results for CA-MRSA strains endemic in USA remain low (0.03–2 mg/L; MIC50, 0.5 mg/L) and combinations with either daptomycin or vancomycin demonstrate enhanced inhibition (SYN or PSYN) and bactericidal activity. No antagonism was observed and these combinations should be considered for severe cases of CA-MRSA infections and studies should be expanded to endemic hospital-acquired MRSA.

P584 Activity of oritavancin against *Staphylococcus aureus* isolates that show heterogeneous resistance to vancomycin

F.F. Arhin, I. Sarmiento, T.R. Parr Jr., G. Moeck (Ville Saint Laurent, CA)

Objectives: Oritavancin is a semi-synthetic glycopeptide that is currently under investigation for use in therapy for severe Gram-positive infections. Its spectrum includes *Staphylococcus aureus* isolates with different vancomycin susceptibility profiles. *S. aureus* isolates heteroresistant to vancomycin (hVISA) are increasingly being reported and have been linked to clinical failure of vancomycin. This study determined the activity of oritavancin against hVISA.
Methods: Clinical isolates that fit the hVISA profile (n = 11) were obtained from the Network on Antimicrobial Resistance in *Staphylococcus aureus* (NARSA) repository and hVISA designations were verified

using (i) teicoplanin screening agar as recommended by the European Antimicrobial Resistance Surveillance System, (ii) the conventional vancomycin and teicoplanin Etest, and (iii) a modified vancomycin and teicoplanin Etest using a higher inoculum and brain heart infusion (BHI) agar plates. MICs were determined by broth microdilution against oritavancin, vancomycin, and teicoplanin according to CLSI guidelines. When testing oritavancin, the procedure was modified to include polysorbate-80 (0.002% throughout test). Plates were read after 24 and 48 h incubation. Reference or quality control strains of different vancomycin susceptibilities (sensitive, intermediate and resistant) were included in all tests as controls.
Results: The hVISA phenotype was confirmed for all isolates. Oritavancin showed potent activity against the hVISAs with an MIC range of 0.25–1 mg/L and an MIC90 of 1 mg/L when the plates are read after 24 h incubation. Oritavancin and comparator MICs read after 48 h of incubation were identical or within one doubling dilution of those read after 24 h of incubation. From the MIC90 values, oritavancin was 2- to 4-fold more potent than vancomycin or teicoplanin.

Agent	MIC range (mg/L)	MIC_{90} (mg/L)
Oritavancin (read after 24 h)	0.25–1	1
Oritavancin (read after 48 h)	0.25–2	2
Vancomycin (read after 24 h)	2–4	4
Vancomycin (read after 48 h)	2–8	8
Teicoplanin (read after 24 h)	2–8	8
Telcoplanin (read after 48 h)	2–16	16

Conclusions: Oritavancin was 4- to 8-fold more potent than the comparator drugs vancomycin and teicoplanin against hVISA strains in broth microdilution assays. This finding supports further development for oritavancin against challenging infections.

P585 Detection of oxacillin resistance in staphylococci: comparison of MicroScan and cefoxitin disc diffusion test

P. Lanzafame, M. Zoppelletto (Trento, IT)

Objectives: Recently Clinical and Laboratory Standards Institute (CLSI) has recommended the use of the cefoxitin disc diffusion (DD) test for detecting meticillin resistance in Staphylococci. The ability of MicroScan panels PBC 21 (Dade Behring, West Sacramento, California, USA) to detect oxacillin resistance in 786 clinical isolates of Staphylococci was evaluated by comparing results with cefoxitin DD test.
Methods: 425 *S. aureus* and 361 coagulase-negative Staphlylococci (CNS) isolates from all body sites were tested. Microdilution susceptibility testing by MicroScan panel PBC 21 was performed according to manufacturer's instructions. From an 18–24-h blood agar plate, isolated colonies were emulsified in 0.85% sterile saline to yield a turbidity of 0.5 McFarland. The suspension was vortexed, and 0.5 ml was added to 25 ml of sterile distilled water containing 0.02% Tween 80. Panels were inoculated by using the MicroScan inoculator set and incubated for 24 h in MicroScan WA 96.
Cefoxitin DD testing was performed according to CLSI M100-S17 guidelines. The inoculum was prepared directly from 18-h agar plates, and MHA plates (Kima, Italy) were incubated at 35ºC for 24 h. Controls included *S. aureus* ATCC 29213 and ATCC 25923. PBP2a agglutination was performed, as a gold standard, when results of the phenotypic methods were not in agreement. PBP2a agglutination (Oxoid, Cambridge, UK) was performed according to manufacturer's instructions.
Results: 112 (26.3%) strains of *S. aureus* and 231 (64.0%) of CNS isolates were resistant by MicroScan, whereas 114 (26.8%) strains of *S. aureus* and 231 (64.0%) of CNS isolates, respectively, were resistant by cefoxitin DD test. The two strains giving discrepant results between MicroScan and the cefoxitin DD test were examined by PBP2a agglutination and they were confirmed as resistent. The inhibition zone diameters of the discrepant *S. aureus* strains were 22 mm, closed to break-point of resistance.
Conclusion: When coagulase-negative Staphlylococci (CNS) were tested, MicroScan showed an excellent performance to detect oxacillin-resistant Staphylococci, in comparison with the cefoxitin DD test (100% sensitivity). Considering *S. aureus* strains, the sensitivity of Microscan was 98.2%, compared to the cefoxitin DD test.

P586 Tigecycline activity against *Staphylococcus aureus* exhibiting multidrug-resistant phenotypes in Europe

D. Sahm, D. Draghi, C. Pillar, C. Thornsberry, M. Dowzicky (Herndon, Collegeville, US)

Objective: *Staphylococcus aureus* (SA) can cause complicated skin and skin structure infections and complicated intra-abdominal infections. Recently in 2006, tigecycline (TIG) was approved in Europe (EU) to treat these infections. SA worldwide are becoming resistant to the most commonly prescribed antimicrobial treatments. TIG is used in healthcare settings where resistance (R), including multidrug resistance (MDR) has become prevalent. Recent outbreaks of this organism have shown clearly that resistance can develop to several different agents. Careful monitoring of new agents such as TIG has become imperative.
Methods: In total, 686 SA isolates were obtained from 28 hospitals in ten countries across EU during 2006 to 2007. Isolates were tested centrally by broth microdilution (CLSI M7-A7). TIG activity was analysed by oxacillin (OX) and MDR status defined as resistance to $\geqslant$3 agents which included OX, minocycline, erythromycin (ERY), clindamycin (CLI), gentamicin, and levofloxacin (LEV). EUCAST breakpoints were used to interpret TIG MIC results and CLSI (M100-S17) breakpoints were used to interpret all other agents, where applicable.
Results: The susceptibility rate overall for SA tested against TIG was 99.4%, with MICs ranging from 0.03 to 1 mg/L. Regardless of OX or MDR status, the TIG modal MIC and MIC90 (mg/L), remained consistent at 0.12 and 0.25, respectively. TIG maintained the lowest MIC90 of all comparators tested. The most common MDR phenotype was 3-drug R with concurrent R to ERY, LEV, and OX (18.1% of all isolates surveyed) followed by 4-drug R with concurrent R to CLI, ERY, LEV, and OX (17.3% of all isolates surveyed). Among MDR populations, TIG maintained >99% susceptibility rate.
Conclusion: TIG has exhibited exceptional in vitro activity against SA including MDR populations. The potential for R to emerge and spread is increasing among SA according to recent CDC reports, therefore continuous monitoring provided by this surveillance initiative is essential to guide clinicians for new therapeutic options.

P587 Analysis of tigecycline activity against *Staphylococcus aureus* based on patient location and clinical specimen source in Europe

N. Brown, D. Draghi, C. Thornsberry, C. Pillar, D. Sahm, M. Dowzicky (Herndon, Collegeville, US)

Objective: Profiling novel agents such as tigecycline TIG for changing resistance trends is important to determine differences among specific patient populations and sites of infection. TIG, a glycylcycline, was approved in 2006 in Europe (EU) for treatment of complicated skin and skin structure infections and complicated intra-abdominal infections. *Staphylococcus aureus* (SA) has the propensity to develop resistance, which can vary with patient locations (PL) and type of infection (as reflected by varied specimen source [SS]). Therefore, analysis of anti-SA TIG activity was stratified according to PL and SS using data collected during 2006 to 2007.
Methods: SA isolates were collected from locations broadly dispersed across EU (including ten countries) and tested centrally using broth microdilution according to current CLSI standards. TIG activity was analysed by PL (outpatient [OP], intensive-care unit [ICU], and inpatient non-ICU [IP]) and SS (blood [BL], respiratory [RP], skin and skin

structure [SST], and urine [UR]). EUCAST breakpoints were used to interpret all TIG MIC results.
Results: See Table.

Org	Category	TIG			
		Total n	MIC range	MIC_{90}	% Susceptible
SA	OP	109	0.06–1	0.5	99.1
	IP	391	0.03–1	0.25	99.2
	ICU	174	0.03–0.5	0.25	100
	BL	162	0.06–0.5	0.5	100
	RP	242	0.03–0.5	0.25	100
	SST	262	0.03–1	0.25	98.5
	UR	16	0.06–0.5	0.5	100

MIC in mg/L.

Conclusion: Based on susceptibility rates and MIC90s, TIG consistently maintained a high level of activity, regardless of PL or SS. Due to the propensity for SA to develop resistance, continued monitoring of the activity of novel agents against this species is imperative.

P588 Bactericidal activity of iclaprim against meticillin-sensitive and -resistant *Staphylococcus aureus*

L. Weiss, M. Bihr, K. Islam, S. Lociuro, S. Hawser (Reinach, CH)

Objectives: Iclaprim is a novel diaminopyrimidine antibiotic that exhibits potent bactericidal activity against major Gram-positive pathogens, notably including MSSA and MRSA. Iclaprim exerts its antibacterial activity by specifically and selectively inhibiting microbial dihydrofolate reductase (DHFR). Intravenous iclaprim recently completed two phase III trials of complicated skin and skin structure infections. This study aimed to determine the bactericidal activity of iclaprim against 16 *S. aureus*, including MSSA and MRSA. Several of these isolates were resistant to the related diaminopyrimidine trimethoprim (TMP).
Methods: MICs were performed against a selection of 16 isolates representative of the MIC range, including MSSA and MRSA, using the CLSI microbroth dilution method. MBCs and time-kill studies were performed under CLSI guidelines.
Results: The MIC range for iclaprim for the 16 isolates of *S. aureus* was 0.015 to 2 ug/ml. The MBC range for all isolates was 0.015–2 ug/ml with MBC / MIC ranging from 1–2. For trimethoprim the MIC range was 0.25–128 ug/ml and the MBC range 0.25–>128 ug/ml. Nine isolates were run in time kill kinetic studies. Iclaprim demonstrated a rapid bactericidal kill with the majority of isolates exhibiting a ⩾ 99.9% reduction in colony forming units following 4.2–7.5 hours exposure to iclaprim. Vancomycin MICs for all isolates ranged from 1–2 ug/ml and MBCs from 1 to >8 ug/ml. The MBC / MIC range was 1–>8. Vancomycin was characteristically slowly bactericidal in time-kill studies.
Conclusions: Iclaprim exhibited rapid bactericidal activity against both MSSA and MRSA, including isolates that were resistant to TMP.

P589 In vitro activity of retapamulin against *Staphylococcus aureus* isolates resistant to fusidic acid and mupirocin

N. Woodford, M. Afzal-Shah, M. Warner, D. Livermore (London, UK)

Objectives: Retapamulin is a novel pleuromutilin antibiotic licensed in the USA in 2007 for the topical treatment of impetigo caused by *S. aureus* and *Streptococcus pyogenes*; It is also licensed in Europe for treatment of impetigo and secondarily infected open wounds caused by the same organisms. We determined its activity in vitro against current *S. aureus* isolates from the UK, including many resistant to fusidic acid and/or highly resistant to mupirocin.
Methods: Six-hundred and sixty four isolates of *S. aureus* were recovered from storage. These had been submitted for reference investigation from laboratories throughout the United Kingdom. MICs were determined on Mueller-Hinton agar in accordance with CLSI guidelines. Susceptibility was categorised using CLSI criteria, where available; otherwise BSAC criteria were used (for mupirocin and fusidic acid).
Results: Susceptibilities of the 664 isolates are summarised below:

Antibiotic	MICs (mg/L)		
	Range	MIC_{50}	MIC_{90}
Retapamulin	⩽0.008–2	0.06	0.125
Mupirocin	⩽0.06–>1024	0.5	1024
Fusidic acid	⩽0.015–>256	2	32
Oxacillin	0.06–>128	128	128
Erythromycin	⩽0.125–>128	128	128
Clindamycin	⩽0.03–>128	0.125	128
Gentamicin	0.015–64	0.5	64

The *S. aureus* included 488 (74%) MRSA (oxacillin MICs >2 mg/L), 336 isolates (51%) resistant to fusidic acid (MICs >1 mg/L), and 254 (38%) with high-level mupirocin resistance (MICs >256 mg/L); 103 (16%) isolates were resistant to both to fusidic acid and to high levels of mupirocin. Retapamulin inhibited 663 (99.9%) isolates at ⩽0.25 mg/L; a single MRSA isolate, also with high level mupirocin resistance required a retapamulin MIC of 2 mg/L.
Conclusions: As a reflection of its unique mode of action, retapamulin has demonstrated excellent activity in vitro vs. *S. aureus*, irrespective of their level of resistance to other antibacterials.

P590 Susceptibility of *Staphylococcus aureus* among skin and wound specimen sources in the United States: laboratory-based surveillance study 2005–2007

G. Tillotson, D. Draghi, D. Sahm, T. del Fabro, K. Tomfohrde, I. Critchley (Louisville, Herndon, US)

Objectives: As meticillin-resistant *Staphylococcus aureus* (SA) infections increase, current data are needed to assess the susceptibility (S) of SA in the US. In this study rates of antimicrobial S for SA were reported from US laboratories from 2005 to 2007 with regional trends of resistance (R) identified.
Methods: The Surveillance Network (TSN®) comprises 296 laboratories from the 9 census regions of the US. TSN laboratories reported S data for antimicrobials by isolate with specimen source description, region, year of isolation, and patient location (PL including outpatient [OP]; inpatient [IN]; intensive-care unit [ICU]). Commonly prescribed agents were studied, these included ciprofloxacin (CIP), levofloxacin (LEV), clindamycin (CLI), daptomycin (DAP), erythromycin (ERY), gentamicin (GEN), oxacillin (OX), linezolid (LIN), and trimethoprim-sulfamethoxazole (SXT). S data from skin and wound specimen sources were studied during 2005 to 2007. Specific phenotypes were further investigated for associated R and multidrug R (MDR) patterns. Data was interpreted using current CLSI standard criteria.
Results: There were >380,000 isolates of SA tested and reported for the period 2005 to 2007. OX R was observed for 57.0% of SA in 2007 with little change from 2005. There was little difference in rates of OX R between OP and IN cohorts. Among all PL in 2007, R rates (%) were 18.6 for CLI; 64.8 ERY; 37 CIP; 39.5 LEV. Generally as expected, isolates from the ICU tended to be slightly more resistant among the agents studied. Regional variation in R rates was noted with the highest rates in the central regions and lowest in New England and Mid Atlantic regions among the agents studied. There was high activity observed for SXT and GEN. LIN R was extremely rare and DAP R was not observed. MDR rates (%) varied among patient location: 28.5 OP; 39.3 IN; and 51.5 ICU.

Conclusions: SA has become OX-resistant in both the community and hospital setting; however, little change was observed in the past 3 years. MDR strains are now common in all settings and empiric therapy should be guided by local susceptibility patterns due to the regional variation. Currently, SXT, GEN, DAP, and LIN exhibited S rates >95%; however, continued monitoring is warranted due to the propensity of this organism to become resistant.

P591 In vitro effect of fusidic acid on staphylococcus strains with macrolide-lincosamid-streptogramin B resistance

E. Sesli Cetin, H. Gunes, A. Aynali, S. Kaya, B. Cicioglu Aridogan, M. Demirci (Isparta, TR)

Objectives: Antimicrobial resistance of staphylococcal isolates continues to be a problem for clinicians worldwide. A major problem in the treatment of *S. aureus* infections is the ability of this pathogen to be resistant to a number of antibiotics. Relationship between meticillin resistance and resistance to other antibiotics has been reported in previous investigations. Fusidic acid displays its antibacterial activity via inhibiting protein synthesis without binding to bacterial ribosomes. This unique mechanism of action prevents cross-resistance between fusidic acid and other antibiotics. This study was carried out in order to determine the in-vitro effect of fusidic acid on stapyhlococcal isolates with macrolid-lincosamide-streptogramine B resistance.
Methods: The study included 532 staphylococcus isolates consisting of 59 MRSA, 101 MSSA, 200 MRCNS and 172 MSCNS. Testing for MLSB and was accomplished by the 'D-zone' test in accordance with the recommendations of the CLSI. Fusidic acid resistance was investigated by agar disk diffusion method according to the criteria of 'Comité de L'antibiogramme de la Société Française de Microbiologie'.
Results: Of 532 staphylococcal isolates, 62.4% were susceptible and 37.6% were resistant to MLSB antibiotics. 62.5% of the resistant isolates exhibited a constitutive resistance phenotype, whereas 37.5% were inducibly resistant. All of 101 MSSA isolates were susceptible to fusidic acid. Susceptibility rate to fusidic acid was higher among strains without MLSB resistance (82.8%) and strains with iMLSB (82.7%) resistance than that observed among isolates with cMLSB (58.4%) resistance. We have also determined that susceptibility to fusidic acid was significantly lower among MRCNS isolates with cMLSB resistance phenotype.
Conclusion: The relatively low susceptibility to fusidic acid detected in our study among strains with MLSB resistance accompanying to meticillin resistance, may be explained with the reports suggesting that multidrug-resistant phenotype can develop as a consequence of continuous exposure of an organism to an antibiotic to which the organism is chromosomally highly resistant. These results indicated that, although fusidic acid can stil be considered as an alternative agent for the treatment of infections caused by meticillin resistant staphylococcal strains, it should be kept in mind that susceptibility rates may be lower than expected if the isolate is also resistant to MLSB antibiotics.

P592 In vitro activity of tigecycline against MRSA, vancomycin-resistant enterococci, and extended-spectrum β-lactamase-producing *Escherichia coli* and *Klebsiella pneumoniae* clinical isolates collected in the Czech Republic

H. Zemlickova, P. Urbaskova (Prague, CZ)

Objectives: To describe the antimicrobial susceptibility to tigecycline in the Czech Republic among isolates of meticillin-resistant *Staphylococcus aureus* (MRSA), extended spectrum β-lactamases (ESBL) producing *Escherichia coli* (n = 90) and *Klebsiella pneumoniae* (n = 100) and vancomycin-resistant enterococci (VRE) (n = 111).
Methods: The isolates were collected in 36 microbiological laboratories partipating in the European Antimicrobial Resistance Surveillance System (EARSS) in the Czech Republic in 2000–2007. The isolates of MRSA (n = 105) and ESBL-producing *K. pneumoniae* (n = 100) were collected from blood. The isolates of ESBL-producing *E. coli* originated from blood (n = 19), urine (11), and wound infections (5). VRE isolates were collected from blood (25), sputum (9), wound (39), urine (34), and stool (5) specimens. A single isolate per patient was accepted. In vitro MICs were determined according to the CLSI (formerly NCCLS) guidelines. The criteria of the European Committee on Antimicrobial Susceptibility Testing (EUCAST) were used to interpret MIC results.
Results: All VRE, MRSA, and ESBL-producing *E. coli* strains were susceptible to tigecycline using EUCAST breakpoints, i.e. ⩽ 0. 25 mg/l, ⩽ 0.5 mg/l and ⩽ 1 mg/l, respectively. As many as 93% of ESBL-producing *K. pneumoniae* strains were inhibited by 1mg/l of tigecycline and five such strains were inhibited by 2 mg/l. Two *K. pneumoniae* strains were resistant to tigecycline with MICs of 4 mg/l.
Conclusion: In the Czech Republic, tigecycline has a good activity against MRSA, VRE, and ESBL-producing isolates of *E. coli*. Strains intermediately resistant (5%) and resistant (2%) to tigecycline were found among ESBL-producing *K. pneumoniae* isolates.

P593 Comparison of daptomycin Etest MICs on Mueller-Hinton, Iso-Sensitest and brain-heart infusion agars with and without calcium supplementation to broth micro-dilution MICs against 20 *Staphylococcus aureus* isolates

L.M. Koeth, J.M. DiFranco (Westlake, US)

Objectives: The effect of calcium concentration on Etest daptomycin minimum inhibitory concentrations (MICs) using three different types of agar was studied.
Methods: The Etest manufacturer (AB Biodisk) recommends BBL Mueller–Hinton agar (MHA) for daptomycin testing, which historically has calcium levels at 25–30 mg/L. MHA (Mast), Iso-Sensitest agar (ISA, Oxoid) and Brain–Heart Infusion agar (BHIA, Difco) with free calcium concentrations of 8.5–52.9 mg/L were used in this study. Twenty clinical isolates of *Staphylococcus aureus* with daptomycin MICs of 0.25–2 mg/L were selected: these were retested in triplicate using CLSI broth microdilution (BMD; calcium concentration of 52.5 mg/L) and tested once with two lots of Etest on each of the study agars. The quality-control strain, *S. aureus* ATCC 29213, was included with each day's testing. The calcium concentration of each agar and broth was determined using ion selective electrode methodology.
Results: As expected, daptomycin MICs decreased with increasing amounts of calcium (Table). Etest MICs using MHA (calcium 28 mg/L) averaged 1.32-, 1.75- and 1.16-fold higher, whereas unsupplemented ISA averaged 3.3-, 2.9- and 2.3-fold higher than those for strains with BMD MICs of 0.5, 1 and 2 mg/L, respectively. The best correlation of Etest and BMD MICs was with MHA (calcium 42.8 mg/L) and ISA (calcium 52.9 mg/L). Etest MICs on BHIA were significantly higher than BMD MICs, and even with a BHIA calcium concentration of 52.6 mg/L, were approximately one doubling dilution higher than BMD gold standard. There was little lot-to-lot variation noted between Etest MICs.

Media	$[Ca^{2+}]$ mg/L	Mean daptomycin Etest MIC (mg/L) for strains with BMD MICs of:		
		0.5 mg/L (n = 8)	1 mg/L (n = 14)	2 mg/L (n = 14)
MHA[a]	28	0.66	1.75	2.32
MHA	42.8	0.53	1.37	2.06
MHA	51.9	0.31	1.36	1.83
ISA (unsupplemented)	8.5	1.63	2.93	4.67
ISA	30.5	0.85	1.74	2.58
ISA	41.9	0.72	1.42	2.32
ISA	52.9	0.53	1.24	1.98
BHIA (unsupplemented)	21.9	2.17	3.73	5.60
BHIA	30.8	1.93	3.21	4.98
BHIA	42.5	1.38	2.83	4.02
BHIA	52.6	1.07	2.23	3.55

[a]Calcium concentration equivalent to BBL unsupplemented MHA.

Conclusion: This study supports the Etest manufacturer's recommendation that MHA is the best choice for susceptibility testing of daptomycin by Etest. However, there was a large percentage (85.7%) of strains with BMD MICs of 1 mg/L that had Etest MICs of 1.5 or 2 mg/L on MHA (calcium 28 mg/L). The daptomycin susceptible breakpoint is 1 mg/L and there is currently no intermediate or resistant breakpoint. Because of the methodology shift in MIC at the daptomycin breakpoint using Etests on MHA containing 28 mg/L Ca^2+, it is suggested that Etest MICs of 1.5 or 2 mg/L are to be considered indeterminate and retested by BMD. ISA or BHIA media are not recommended for use with the daptomycin Etest strip because falsely resistant interpretation could result.

P594 Confirmation of high-level mupirocin resistance in *S. aureus* isolates using the mupA Evigene™ kit

R.L. Skov, L. Hansen (Copenhagen, DK)

Objectives: Mupirocin is the only anti *Staphylococcus aureus* topical antibiotic licensed for eradication treatment of nasal carriage of *S. aureus*. Mupirocin resistance occurs both as "high level" or "low level." Since application of mupirocin ointment into the external nares results in concentrations >20,000 mg/L, only high-level resistance (MIC of >256 mg/L) is significant in this setting. High-level resistance is caused by the expression of the mupA (or ileS-2) gene that encodes an additional isoleucyl tRNA-synthetase that is not bound by mupirocin. In this study we investigated the mupA Evigene™ kit for confirmation of mupA high-level resistance in isolates screened positive using a 5 µg mupirocin disc.
Material and Methods: A total 39 out of 4692 clinical *S. aureus* isolates (1223 were MRSA) with an inhibition zone <20 mm against a 5 µg mupirocin disc were investigated. The 39 isolates were tested by mupA Evigene™ hybridisation assay with capture and detection probes for the mupA gene producing a red colour, assay time of 3.5 hours. Wells were read both visually and using an ELISA reader at 490nm, using an OD of 0.50 as cut off. The isolates were further MIC tested by E-test (using the manufacturer's instructions) and a 200 µg mupirocin disc using confluent inoculum on Mueller Hinton agar. *S. aureus* ATCC 29213 (mupA negative) and AIS2006–079 (mupA positive) were included in all runs.
Results: Six isolates, all MRSA, were found positive for mupA by the mupA Evigene™ both visually and using Elisa reader (OD 2.0–2.7 for positive compared to <0.16 for mupA negative isolates). All 6 mupA positive isolates had MIC >1024 mg/L and inhibition zones <13mm using a 200 mu;g disc, whereas mupA negative isolates had MICs between 0.064 and 8 mg/L and inhibition zones between 20 and 37mm by disk diffusion.
Conclusion: In summary, the mupA Evigene™ identify isolates with high-level resistance to mupirocin fast (3.5 hours) from isolates with low resistance. This investigation supports the use of mupA Evigene™ in clinical settings for the confirmation of high-level resistance in mupirocin resistant *S. aureus*.

P595 Evaluation of the Vitek AST-GP66™ panel and Vitek Two™ for susceptibility testing of selected antibiotics with coagulase negative staphylococci

M. John, J. Daniel, D. Diagre, S. Milburn, B. Wilson, Z. Hussain (London, CA)

Objective: To compare the AST-GP66™ panel and Vitek Two™ with agar dilution for determination of susceptibility of antibiotics commonly used to treat coagulase negative staphylococci (CoNS) infections (clindamycin, erythromycin, linezolid, oxacillin and vancomycin).
Method: Susceptibility was performed on 693 CoNS isolates, comprising 14 species. Panels were set up and tested as per the manufacturer's instructions. Agar dilution was performed using CSLI methods. The Mec A status of isolates was determined using PCR. Agar dilutions covered all the MIC values obtained from the Vitek panels. Differences of ⩾ 2 dilutions were noted. In addition, MIC's were converted to qualitative categories (sensitive or resistant) according to CSLI guidelines. Category errors were then assessed as very major (resistant by Vitek™, sensitive by agar dilution), major (sensitive by Vitek™, resistant by agar dilution) or minor (change from sensitive to intermediate).
Results: In total 3,485 MIC values were generated by each method. 3,443 MIC values were evaluated, out of which 126 had ⩾ 2 dilution differences (3.6%). The remaining pairs differed by ⩽ 1 dilution. Altogether there were 6 very major errors, 22 major errors and 13 minor category errors. For clindamycin there were no very major errors, 7 major and 10 minor category errors. For erythromycin there were 5 very major, 11 major and 2 minor errors. For linezolid there was 1 major error (no very major or minor) and for vancomycin 1 minor (no very major or major). For oxacillin there was 1 very major and 3 major (no minor) category errors (only calculated for *S. epidermidis* and *S. scheifleri*). For other species the MIC did not necessarily correlate with the presence of the MecA gene. The cefoxitin screen (6 µg) did not correlate well with the presence of the Mec A gene.
Conclusion: Vitek Two™ and Vitek AST-GP66™ panels were reliable for determination of susceptibility of CoNS to clindamycin, erythromycin, linezolid, oxacillin and vancomycin. Our results also confirm that CLSI guidelines (presence/absence of MecA)should be followed for interpretation of MIC's between ⩾ 0.5 and 4.0 for oxacillin. The cefoxitin screen was not useful in identifying MecA positive isolates.

P596 Validation of agar dilution for susceptibility testing of coagulase-negative staphylococci to tigecycline

M. John, J. Daniel, D. Diagre, B. Wilson, S. Milburn, Z. Hussain (London, CA)

Objectives: To compare in vitro susceptibilities of a large series of speciated coagulase negative staphylococci (CoNS) to tigecycline using the E-test™ and agar dilution. A secondary objective was to determine whether tigecycline agar dilution plates were stable over a two week period.
Methods: Susceptibility was performed on 693 CoNS isolates, comprising 14 species. E-test has been validated as a method for determining susceptibility to tigecycline and was performed according to the manufacturer's instructions and read in a blinded fashion by two examiners. Agar dilution was performed using methodology described by the CLSI. In addition, a proportion of isolates were re-tested by agar dilution for a period of two weeks to ascertain the stability of tigecycline plates. MIC's were converted to qualitative categories (sensitive or resistant) according to CSLI guidelines. Category errors were then assessed as very major (resistant by E-test™, sensitive by agar dilution) or major (sensitive by E-test™, resistant by agar dilution).
Results: Tigecycline is bacteriostatic against CoNS, which made the determination of MIC's by E-test™ at times difficult to read. Overall, MIC's determined by agar dilution were one dilution higher than those determined by the E-test™. When converted to qualitative categories (sensitive or resistant) this did not result in category changes in most cases when interpreting susceptibility. Overall there were 3 very major category errors (resistant by E-test™, sensitive by agar dilution) and 30 major errors (sensitive by E-test™, resistant by agar dilution). Almost all category errors occurred with *S. haemolyticus* (34%) and *S. epidermidis* (11%). MIC's by agar dilution did not change when the testing was repeated over a two week period.
Conclusion: Apart from for *S. haemolyticus*, agar dilution appears to be a valid method for determining susceptibility of CoNS to tygecycline. In addition, once agar dilution plates have been prepared the tigecycline remains stable for at least 2 weeks at 2–8ºC.

P597 Oritavancin sterilises in vitro biofilms of *Staphylococcus epidermidis* and vancomycin-susceptible and -resistant enterococci

A. Belley, E. Neesham-Grenon, T. Parr Jr., G. Moeck (St-Laurent, CA)

Objectives: Oritavancin (ORI) is a semi-synthetic lipoglycopeptide that is currently in clinical development for serious Gram-positive

infections. We sought to determine whether ORI can eradicate biofilms of *Staphylococcus epidermidis* and vancomycin-susceptible and -resistant enterococci, which are prominent in infections of indwelling devices and infective endocarditis, respectively.

Methods: The following strains were used for in vitro biofilm studies: vancomycin (VAN)-susceptible *Enterococcus faecalis* ATCC 29212 (VSE), VAN-resistant *E. faecalis* ATCC 51299 (VanB VRE), *E. faecium* ATCC 51559 (VanA VRE), *S. epidermidis* ATCC 12228 and the slime-producing strain *S. epidermidis* ATCC 35984. Biofilms were established in MBEC^{TM} Physiology & Genetics Assay plates (Innovotech; Edmonton, Canada). Minimal biofilm eradication concentrations (MBEC) values for single antimicrobial agents (ORI, VAN, linezolid [LIN]) and for agents in combination (ORI with moxifloxacin [MOX] or rifabutin [RFB]) were determined in three independent experiments.

Results: Biofilms of VSE, VanB VRE and VanA VRE were sterilised by ORI at MBECs of 2 to 4 mg/L following 24 h of drug challenge. In contrast, the VSE and VRE biofilms were tolerant to VAN and LIN, exhibiting MBEC values >128 mg/L for both agents. Biofilms of *S. epidermidis* ATCC 12228 were sterilised by ORI at an MBEC of 2 to 4 mg/L but also exhibited tolerance to VAN and LIN with MBECs >128 mg/L. Sterilisation of *S. epidermidis* ATCC 35984 biofilms required combinations of ORI (MBEC of 4 mg/L) and MOX (MBEC of 4 mg/L), or ORI (MBEC of 4 mg/L) and RFB (MBEC of 0.125 mg/L).

Conclusion: Oritavancin shows promise as monotherapy or in combination against medically important biofilms derived from VSE, VRE and *S. epidermidis* strains.

P598 Prevalence of antimicrobial resistance of enterococcus species isolated from blood patients with haematological malignancies in Russia

A. Mironova, A. Brilliantova, E. Trushina, I. Phrolova, L. Speranskaya (Moscow, RU)

Objective: The aim of this study was to determine the prevalence of enterococcal species isolated from blood cultures and their antibiotic susceptibility in Hematological Centre throughout a 5-year period (January 2003 – November 2007).

Methods: Enterococci were identified by basic tests and by PCR amplification of ddl genes. Minimal Inhibitory Concentrations (MICs) were determined by broth microdilution method (CLSI). Resistance genes were detected by PCR.

Results: A total of 80 enterococcus species were collected from January 2003 to November 2007. Most were *Enterococcus faecium* (65), the rest were *E. faecalis* (14) and E. durans (1). The number of *E. faecium* cases per year increased from 63% (10/16) in 2003 to 86% (18/21) in 2007. *E. faecium* strains (vs. *E. faecalis*) were more resistant to the following antibiotics: levofloxacin (98 vs. 33%), erythromycin (94 vs. 64%), highly-level resistant to streptomycin (89 vs. 43%) and gentamicin (97 vs. 50%); except chloramphenicol (11 vs. 43%) and tetracycline (26 vs. 64%). Five (7.7%) *E. faecium* isolates were resistant to vancomycin (MIC ranged from 128 to 1024 mg/L) and teicoplanin (MIC from 16 to 32 mg/L) and carried vanA genes. *E. faecium* showed an increase in vancomycin resistance from 7% (1/15) in 2005 to 10% (1/10) in 2006 and 17% (3/18) in 2007 and a trend to decrease chloramphenicol resistance from 20% in 2003 to 0% in 2006 and 2007. After long treatment with linezolid, VREF strain reisolated from blood displayed low level linezolid-resistance with a MIC = 4 mg/L.

Conclusion: *E. faecium* was the predominant enterococcal specie isolated from blood cultures. The rate of vancomycin-resistant *E. faecium* bloodstream infections has increased since 2005 to 2007. *E. faecium* was found to be increasingly chloramphenicol sensitive. The occurrence of low level linezolid resistant is a threatening problem for Russian hematological patients.

P599 In vitro activity of tigecycline against enterococci

A. Lesenne, J. Aires, N. Bourgeois-Nicolaos, B. Couzon, F. Doucet-Populaire (Paris, Le Chesnay, FR)

Objectives: This study was undertaken to determine in vitro activity of tigecycline, the first representative of glycylcyclines, against 65 enterococci French isolates and to correlate this activity with their resistance gene content. Moreover, the activity of tigecycline was compared to that of other tetracyclines (tetracycline, minocycline, and doxycycline) and 4 main antibiotics used in the treatment of enterococci infections (amoxicillin, vancomycin, linezolide, quinupristine-dalfoppristine (QP)).

Methods: MICs were determined using the CLSI agar dilution method. We studied 55 clinical isolates of enterococcus of human origin and 10 isolates of animal origin (30 *Enterococcus faecalis* and 35 *Enterococcus faecium*) among which 11 strains resistant to glycopeptides (VRE) harbouring the vanA or vanB gene. The presence of the 2 main genes encoding tetracycline resistance in Enterococci: tet (M) (ribosomal protection) and tet (L) (efflux) was detected by PCR on all the strains.

Results: Among the 65 isolates studied, 22, all *E. faecium*, were resistant to amoxicillin (MIC range 0.125–64 mg/L). Only 49% of the strains were susceptible to QP. All the strains were susceptible to linezolide (MIC range 1–2 mg /L). Among tetracyclines antibiotics, tetracycline was the least active molecule with 41% (n = 27) of susceptible strains (MIC90: 64 mg/L); 46% (n = 30) strains were susceptible to doxycycline (MIC90: = 16 mg/L) and 54% (n = 36) to minocycline (CMI90: 64 mg/L). All the 43 tetracycline resistant strains ((MIC > 8 mg /L) possessed at least one of the 2 genes: tet (L) or tet (M). All the studied strains, whatever their phenotype and genotype of tetracyclines resistance, were highly susceptible to tigecycline with MIC90 equal to 0.125 mg/L (MIC range 0.03–0.125 mg/L). No difference of susceptibility was observed according to the species and to the phenotype of resistance.

Conclusion: Tigecycline presents a good in vitro activity against *E. faecalis* and *E. faecium* including VRE. This activity is not modified in the presence of genes tet (M) and tet (L) the most frequent in Enterococci encoding tetracyclines resistance.

P600 Impact of the new CLSI non-meningitis penicillin breakpoints on the reporting of antimicrobial susceptibility in pneumococcal infections

L-H. Su, C-H. Chiu, T-L. Wu, A-J. Kuo, C-F. Sun (Taoyuan, TW)

Objectives: The present breakpoints for defining the susceptibility of meningeal pneumococcal isolates to cefepime, cefotaxime, and ceftriaxone are different from those for nonmeningeal pneumococcal isolates due to the attainability of these agents in the cerebral spinal fluids. However, although the penicillin breakpoints were defined based upon measured penicillin concentrations in the cerebral spinal fluids after intravenous infusions and upon meningitis treatment failures, the breakpoints have been applied to nonmeningeal pneumococcal isolates since the definitions were developed in the late 1970s. In 2008, a new set of breakpoints will be published by the CLSI to be used for defining the penicillin susceptibility of nonmeningeal pneumococcal isolates. The present report aimed to assess the impact of the new breakpoints on the reporting of pneumococcal susceptibilities.

Methods: The MICs of penicillin to pneumococcal isolates were examined by the standard broth microdilution method as recommended by the CLSI. The results between 2000 and June 2007 were collected and analysed against both of the old (susceptible, $\leqslant$ 0.06 mg/L; intermediate, 0.12–1 mg/L; resistant, $\geqslant$ 2 mg/L) and new (susceptible, $\leqslant$ 2 mg/L; intermediate, 4 mg/L; resistant, $\geqslant$ 8 mg/L) definitions.

Results: Results from a total of 3156 pneumococcal isolates, including 1.1% of meningeal isolates, were available for analysis. With the old definition, the rate of penicillin nonsusceptibility increased from 88.6% in 2000 to 92.9% in 2007 (average, 91.2%). With the new definition, the rate of penicillin nonsusceptibility decreased from 34.5% in 2000 to 2.5% in 2007 (average, 20.4%). Notably, the proportion of isolates with

the MICs of 1–2 mg/L increased significantly from 41.4% in 2000 to 70.7% in 2007.
Conclusions: Application of the new breakpoints will result in a significantly lower rate of penicillin nonsusceptibility in nonmeningeal pneumococcal isolates. Clinicians may feel more confident in using penicillin for the treatment of pneumococcal infections, and thus the use of other advanced drug classes may be exempted. However, as the population of pneumococcal isolates with borderline penicillin susceptibility (MIC, 1–2 mg/L) is increasing, the regimen of penicillin treatment must be closely monitored to achieve a satisfied therapeutic outcome.

P601 A longitudinal perspective on *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* resistance trends in Europe: from GLOBAL surveillance studies

D. Sahm, N. Brown, C. Pillar, D. Draghi, M. Obot-Tucker, C. Thornsberry (Herndon, US)

Objective: *Streptococcus pneumoniae* (SP), *Haemophilus influenzae* (HI), and *Moraxella catarrhalis* (MC) are three of the most common pathogens associated with community-acquired pneumonia (CAP). Changes in the prevalence of resistance (R) and multi-drug R (MDR) among these pathogens can become problematic for clinicians treating infections. R rates can vary according to regional distributions. The GLOBAL Surveillance (SUR) initiative is a longitudinal study that benchmarks antimicrobial R among respiratory pathogens (RPs).
Methods: SP, HI, and MC isolates taken from patient specimens were collected from 6 countries in Europe (EU): Belgium (Bel), France (Fr), Germany (Gr), Italy (It), Spain (Sp), and the United Kingdom (UK). The years (Y) of collection were 03–04 (04), 05–06 (06) and 07 (respectively) for SP (N: 3213; 1542; 755); HI (N: 3183; 1578; 860) and MC (N: 722; 379; 163). All isolates were centrally tested by broth microdilution and interpreted according to CLSI standards (M7-A7 M100-S17). Data were analysed according to β-lactamase (BL) status [positive (+) and (−)] for HI and MC; for SP analysis included penicillin (PEN) and MDR phenotypes [R to ⩾ 2 drugs: PEN, cefuroxime, trimeth-sulfa, azithromycin (AZI), and tetracycline].
Results: Overall for SP, PEN-R (%) was 12.7 in 04, 12.8, in 06 and 11.8 in 07. The PEN-R rates (%) varied in 04, 05, and 07, respectively: Bel (7.4; no data; 6.8), Fr (32.9; 23.7; 19.4), Gr (3.5; 5.7; 1.3), It (6.8; 7.7; 21.2), Sp (25.4; 20.8; 7.9), and UK (2.2; 2.8; 3.9). The prevalence (%) of MDR-SP ranged from 3.4 (UK) to 44.2 (Bel) in 04, 4.3 (UK) to 33.2 (Fr) in 06, and 12.4 (UK) to 48.2 (It) in 07. >98% of MDR-SP were susceptible (S) to levofloxacin (LFX). For HI, BL + rates (%) varied by country from 8 (Bel) to 32.3 (Fr) in 04, 7.3 (Gr) to 23.4 (Fr) in 06, and 3 (It) to 18.9 (UK) in 07. Based on MIC90, LFX and ceftriaxone were the most active agents tested against HI, regardless of BL status with MIC90s of 0.015–0.03 mg/L all Y. For MC, overall BL + rates (%) increase by Y slightly: 96.4 (04), 96.6 (06), and 98.2 (07). Regardless of phenotype, LFX and AZI were the most potent agents against MC, based on MIC90s (⩽0.06 mg/L).
Conclusion: LFX showed potent activity against the RPs studied. LFX was active among PEN-R and MDR-SP and BL +/− HI and MC. %S among SP, HI, and MC remained high all Y for LFX. Continued SUR is warranted to monitor any changes that may occur among agents used to treat CAP pathogens.

P602 Antimicrobial resistance in *Streptococcus pneumoniae* and *Haemophilus influenzae* isolated from respiratory tract infections between 2001 and 2007

B. Altun, D. Gur (Ankara, TR)

Objectives: Local data on antimicrobial resistance is necessary in the empirical therapy of respiratory tract infections. The rate of antimicrobial resistance in respiratory isolates of *Haemophilus influenzae* and *Streptococcus pneumoniae* from children were determined and were compared by year.
Methods: Antimicrobial resistance in respiratory isolates of *H. influenzae*(n = 565) and *S. pneumoniae* (n = 736) were investigated. Susceptibility to penicillin and cefotaxime were determined by E-test (AB Biodisk, Solna, Sweden) in *S. pneumoniae*. In vitro activity of the remaining antimicrobials were evaluated by disk diffusion method according to CLSI criteria. for *H. influenzae*, strains β-lactamase production was detected using chromogenic nitrocefin disk method (BD, Sparks, USA).
Results: Resistance rates are given in the Table. β-lactamase production was detected in 3.4% of *H. influenzae*. Penicilin (intermediate and high-level) and trimethoprim-sulfamethoxazole (TMP/SMX) resistance rates were 34.7% and 44.4% in 2001 and were 55.2% and 60.9% respectively in 2007 for *S. pneumoniae*.

Table: Overall rates of resistance to antimicrobial agents in respiratory *H. influenzae* and *S. pneumoniae* isolates (2001–2007)

	H. influenzae			*S. pneumoniae*		
	n	I (%)	R (%)	n	I (%)	R (%)
Ampicillin	565	–	5.5	ND	ND	ND
Penicillin	ND	ND	ND	736	38.1	4.2
Ampicillin/sulbactam	565	–	0.7	ND	ND	ND
Cefaclor	518	2.9	2.5	ND	ND	ND
Cefotaxime	565	0.2	–	736	–	–
Meropenem	535	–	–	ND	ND	ND
Clarithromycin	557	0.9	2.5	ND	ND	ND
Erythromycin	ND	ND	ND	736	1.1	21.6
TMP/SMX	565	0.4	18.5	736	7.7	45.6
Ofloxacin	509	–	–	736	1.2	0.2
Levofloxacin	ND	ND	ND	460	0.7	–
Tetracycline	514	0.2	0.9	702	2.6	24.5
Chloramphenicol	ND	ND	ND	736		10.7

ND: not determined.

Conclusions: Highest rate of resistance has been observed for trimethoprim-sulfamethoxazole in both microorganisms. β-lactamase production in *H. influenzae* has not increased over the years. Penicillin resistance has increased in *S. pneumoniae*. Resistance to levofloxacin is very low at present. Monitoring of the resistance rates may help the clinicians in the empirical therapy of respiratory infections due to *S. pneumoniae* and *H. influenzae*

P603 Bactericidal activity of moxifloxacin and levofloxacin against *Streptococcus pneumoniae* with dual gyrA and parC mutations

R. Davidson, E. Campbell (Halifax, CA)

Objectives: *Streptococcus pneumoniae* (Sp) is the most common bacterial cause of respiratory tract infections (RTIs). RTIs are virtually always treated empirically without the benefit of susceptibility tests. Although fluoroquinolone-resistant Sp isolates are uncommon, these have been associated with clinical failure. Thus, we sought to determine the efficacy of moxifloxacin (MXF) and levofloxacin (LFX) against isolates with double-step parC/gyrA mutations.
Methods: Eight strains of Sp collected via an active surveillance programme were characterised for gyrA and parC QRDR mutations by PCR and DNA sequencing. MICs of MFX and LFX were evaluated using a microbroth dilution method and their bactericidal activity determined using Mueller–Hinton broth supplemented with 5% lysed horse blood in a pharmacodynamic model. Sp were inoculated at a density of 1 x 10^6 CFU/ml, incubated at 35ºC, and examined for viable growth at 0, 1, 2, 4, 6, 12, and 24 h after exposure to MXF or LFX. Drug concentrations approximated epithelial lining fluid (ELF) levels or Cmax of MXF (400 mg) and LFX (500 mg). Protein binding was accounted for and drug elimination over a 24-h dosing interval simulated.

Results: All eight strains in the study had documented gyrA and parC mutations consistent with fluoroquinolone resistance. MICs ranged between 1 and 4 mg/L for MXF and between 8 and 32 mg/L for LFX. At ELF concentrations, MXF was bactericidal against all eight isolates and LFX was bacteriostatic against four strains and had characteristics comparable with the growth control in four strains. At Cmax concentrations, MXF was bactericidal against five strains and bacteriostatic against three strains, LFX had characteristics comparable with controls for all eight strains.
Conclusions: Only MXF consistently achieved bactericidal activity against high level (parC/gyrA) fluoroquinolone-resistant *S. pneumoniae* at either ELF or Cmax concentrations. When treating patients without the benefit of susceptibility testing, MXF has the greatest likelihood of achieving bacterial eradication, even when challenged with fluoroquinolone resistant *S. pneumoniae*.

P604 In vitro activity of tigecycline against contemporary clinical isolates of *Streptococcus pneumoniae*

J. Blondeau, S. Borsos (Saskatoon, CA)

Objectives: *Streptococcus pneumoniae* (SP) remains amongst the most prevalent causes of community-acquired respiratory tract infections. Both penicillin and multidrug resistant strains may compromise drug use and ongoing interest in newer antimicrobial agents necessitates ongoing testing of clinical strains. We determined the in vitro activity of tigecycline against blood and respiratory SP isolates.
Methods: Minimum inhibitory concentration (MIC) testing was based on current Clinical and Laboratory Standards Institute procedure by microbroth dilution using 10^5 cfu/ml tested against doubling drug dilutions in appropriate media. Following incubation, the lowest drug concentration preventing growth was the MIC. For mutant prevention concentration (MPC) testing, $\geqslant 10^9$ CFUs were applied to solidified Todd-Hewitt broth containing doubling drug dilution and following incubation, the lowest concentration preventing growth was the MPC.
Results: A total of 174 isolates (47 blood, 127 respiratory) were tested. MIC values were not different for blood versus respiratory isolates. The MIC50/90/100 (mg/L) values were 0.031/0.063/0.063. The MIC range values were 0.008–0.063 mg/L. Against penicillin intermediate and resistant strains, tigecycline MIC values ranged from 0.008–0.063 mg/L. MPC values ranged from 0.063–0.5 mg/L.
Conclusions: Tigecycline was highly active in vitro against contemporary blood and respiratory SP isolates. No isolate had an MIC above 0.063 mg/L and MIC results were not different against penicillin susceptible or resistant strains. MPC values were 0.063–0.5 mg/L. This data suggests tigecycline to be highly active against SP isolates and also demonstrates a low propensity to select for resistance.

P605 The impact of blood in media on the determination of mutant prevention concentration testing of tigecycline against clinical isolates of *Streptococcus pneumoniae*

C. Hesje, S. Borsos, J. Blondeau (Saskatoon, CA)

Objectives: Tigecycline (Tig) is the first of a new class of compound – glycylcyclines – with potent in vitro activity against penicillin-susceptible and multi-drug resistant strains of *Streptococcus pneumoniae* (SP). The mutant prevention concentration (MPC) defines the drug concentration threshold blocking the growth of resistant bacterial sub-populations present in high density bacterial inocula. We measured the minimum inhibitory concentration (MIC) and MPC values for Tig against SP isolates and compared MPC results on solidified Todd-Hewitt broth (STHB) to those on STHB + 5% sheep red blood cells (SRBC) and to those on tryptic soy agar (TSA) + 5% SRBC.
Methods: For MIC testing, the recommended CLSI procedure was followed: 10^5 cfu/ml tested against doubling drug dilutions in THB with incubation at 35–37 degree C in 5% CO2 for 18–24 hours. For MPC testing, $\geqslant 10^9$ CFUs were added to drug containing agar plates: 1) TSA-5% SHRB, 2) STHB (1.5% agar) and 3) STHB + 5% SRBC incubated as described for 24–48 hours and screened for growth. The lowest concentration preventing growth was the MIC or MPC depending on method.
Results: For SP isolates (including ATCC 49416) MIC50, MIC90 and MIC range values (ug/ml) were 0.016, 0.031 and <0.008–0.31 respectively. MPC50, MPC90 and MPC range values (ug/ml) on STHB were 0.063 (75%), 0.5 and 0.063–0.5 as compared to 8, >8 and 4–>8 on STHB + 5% SRBC and 8, ⩾16, ⩽1–⩾16 on TSA + 5% SRBC. MPC values for SP ATCC 49416 were 0.125 ug/ml on STHB versus 8 ug/ml on STHB + 5% SRBC.
Conclusions: Tig was highly active in vitro against SP with MICs ⩽0.031 ug/ml. MPC values ranged from 0.063–0.5 ug/ml on STHB and were substantially higher when test media contained blood (>90% ⩾4 ug/ml; >37% ⩾8 ug/ml). This data suggests that SP testing of Tig on blood containing media yields falsely elevated values. STHB appears to be a more suitable media for SP MPC testing against Tig. Tig appears to have a low propensity to select for resistance.

P606 Regional trends in telithromycin and azithromycin resistance among *Streptococcus pneumoniae* isolates

V. Allizond, G. Banche, J. Roana, N. Li Vigni, N. Mandras, D. Scalas, V. Tullio, N. Carlone, D. Savoia, A. Barbui, A. Cuffini (Turin, Biella, IT)

Objectives: This study compared the in vitro activity of telithromycin, the first ketolide developed for clinical use, with that of azithromycin, one of the most commonly used macrolide for treatment of respiratory tract infections, against 198 *Streptococcus pneumoniae* isolates at some North West Italy's hospitals between 2005–2007. Erythromycin-resistance phenotypes were determined to correlate the different bacterial resistant pattern to antimicrobial susceptibility.
Methods: The determination of minimal inhibition concentration (MIC) was carried out using the microdilution broth method according to Clinical and Laboratory Standards Institute (CLSI) with an inoculum of 10^5 cfu/ml and antimicrobial concentrations ranged from 0.03 to 64 mg/L. Minimal bactericidal concentration (MBC) was determined by plating 0.1 ml from the wells showing no visible growth on agar plates and incubating for 18 h. The erythromycin-resistance phenotype was determined by the triple-disk test described by Giovanetti et al. Commercial disks of erythromycin, clindamycin and josamycin were used.

Table. In vitro antimicrobial activity of telithromycin and azithromycin against erythromycin-susceptible and erythromycin-resistant *S. pneumoniae* isolates

Isolates[a]	Drug	Number of strains having MIC (mg/L) equal to:											
		⩾64	32	16	8	4	2	1	0.5	0.25	0.12	0.06	⩽0.03
Erythromycin-susceptible (n = 137)													
	TEL									20		12	105
	AZM								31	51	31	12	12
Erythromycin-resistant (n = 61)													
$cMLS_B$ (n = 26)	TEL							2	4		6	12	2
	AZM	22	2	2									
M (n = 26)	TEL							14	10				2
	AZM	6	18		2								
$iMLS_B$ (n = 9)	TEL										4	1	4
	AZM	9											

[a] 198 *S. pneumoniae* isolates. $cMLS_B$ = constitutive resistance; M = M resistance; $iMLS_B$ = inducible resistance.
AZM = azithromycin; TEL = telithromycin.

Results: 69.2% of the *S. pneumoniae* isolates were erythromycin-susceptible (Ery-S). Among the 30.8% erythromycin-resistant (Ery-R) pneumococci, 42.6% expressed the constitutive MLSB phenotype, 42.6% the M phenotype and 14.8% the inducible MLSB phenotype. Azithromycin showed a high activity against *S. pneumoniae* Ery-S strains, with MIC values ranging from ⩽ 0.03 to 0.5 mg/L. The Ery-R isolates were all resistant to azithromycin (MICs ⩾ 8 mg/L). On the contrary, both Ery-S and Ery-R streptococci isolates were homogeneously susceptible to telithromycin, with MIC values ⩽ 1 mg/L, according to CLSI. Telithromycin and azithromycin MBC values were

generally higher than the corresponding MICs, reflecting the same trend observed for MIC values for all the strains.

Conclusion: The uniform activity of telithromycin against *S. pneumoniae*, including Ery-R isolates, suggests that this ketolide may offer a valuable alternative for treatment of streptococcal infections. Furthermore, in addition to several other reports, even the findings from this regional study, emphasize that an active surveillance of phenotype distribution and antibacterial resistance in pneumococci is essential to guide the effective use of empirical treatment option for streptococcal infections.

P607 Antimicrobial susceptibility of *Lactobacillus* strains used in probiotic products

G. Blandino, I. Milazzo, D. Nicolosi, S. Puglisi, D. Fazio (Catania, IT)

Objectives: Antimicrobial susceptibility testing of *Lactobacillus* spp. used in probiotics products is advisable for checking biosafety. In fact probiotics should not carry acquired resistance potentially transferable to endogenous bacteria; moreover, intrinsic resistance could prevent treatment of a infection due to *Lactobacillus* spp. However there is still a lack of agreement on the guidelines of the susceptibility testing of *Lactobacillus* spp. and of the interpretative breakpoints. The aim of this study was to test the susceptibility of *Lactobacillus* sp.using the guidelines of the new 2006 CLSI M45-A document for infrequently isolated or fastidious bacteria.

Methods: We tested the susceptibility to ampicillin, meropenem, vancomycin, gentamycin, erythromycin, clindamycin (recommended by CLSI, 2006) and, also, 2 cephaloporins and 2 fluoroquinolones of 19 *Lactobacillus* isolates from 5 fermented foods, 5 food supplements and 4 vaginal products available in Italy. The strains were isolated using different media under standardised cultivation conditions. The species designation was determined by standardised methods including API kits and PCR. MICs were obtained by broth microdilution according to 2006 CLSI document.

Results: The MIC results were evaluated using CLSI breakpoints to predict clinical success and microbiological breakpoints suggested by FEEDAP Committee (EFSA J., 2006) to distinguish probiotic strains with acquired resistance. All the *Lactobacillus* isolates were β-lactamase negative and susceptible to ampicillin and imipenem by both breakpoints. The isolates of *L. plantarum*, *L. salivarius* and *L. paracasei* confirmed intrinsic-resistance to vancomycin; the other isolates tested had MIC $\leqslant$ 4 mg/L (susceptibility breakpoint). Gentamycin had poor activity against *Lactobacillus* isolates. Atypical resistance to erythromycin occurred in 1 *L. salivarius* isolate. A wide range of MICs was observed for cephalosporins and fluoroquinolones.

Conclusion: The results showed that *Lactobacillus* isolates used in probiotics do not show particular risk of acquired and potentially transferable resistance. However, for *Lactobacillus* isolates involved in serious infections, the marginal susceptibility or resistance to some relevant drugs should be taken into account.

P608 Effects of tylosin and chlortetracycline on the proliferation of antibiotic-resistant bacteria in a simulated river water ecosystem

J. Muñoz-Aguayo, K. Lang, R. Singer (Saint Paul, US)

Objective: The objective of this study was to examine the effects of varied concentrations of chlortetracycline (CTC) and tylosin tartrate salt (TYL) on the selection of resistance in aerobic bacterial populations in a simulated river water ecosystem.

Methods: Six replicates of a 10-day experiment using river water in continuous flow chemostats were conducted. In each replicate, 1 chemostat served as the control to which no antibiotic was added. In the first two replicates, TYL was added at concentrations of 100 ng/L and 10 μg/L. In replicate 3, TYL was added at concentrations of 10 μg/L and 50,000 μg/L, and in replicates 4 through 6, TYL was added at concentrations of 10 μg/L, 1000 μg/L and 50,000 μg/L. The amount of TYL present in the chemostats from samples taken on days 0, 3, 7 and 10 was quantified with a commercially available competitive enzyme-linked immunosorbent assay. The viable bacterial count was determined by plate count from days 0 through 10 using 1/10-strength LB agars with and without 16 μg/ml of TYL and Columbia CNA agars with and without 16 μg/ml of TYL. The presence of the erm (B) gene in the bacteria within the chemostats was assessed on days 0 through 10 by extracting DNA from a chemostat sample followed by PCR using previously published primers. Results of the TYL replicates were compared to the CTC replicates that were conducted previously.

Results: There was no significant difference among treatment groups in the total bacterial load within the chemostats when assessed on LB agar plates (8–9 log10 CFU/ml). Although the chemostats with higher levels of TYL had lower bacterial loads on Columbia CNA agar and Columbia CNA agar with 16 μg/ml of TYL, there was no difference among chemostats in the proportion of the total bacterial load that grew on CNA agar with 16 μg/ml of TYL. No differences among chemostats were observed when bacteria were grown on LB agar with 16 μg/ml of TYL. The gene erm (B) was detected on many days of the replicates, mainly in the high TYL concentration chemostats.

Conclusions: Low concentrations of TYL in this in vitro experiment did not select for increased levels of resistant bacteria. This is identical to the observation in the CTC experiment. Whereas high doses of CTC did select for tetracycline-resistant bacterial populations, high doses of TYL did not appear to have this effect. These results question the biological significance of low tylosin concentrations observed in the environment.

P609 Establishment of reference substances for the microbiological assay of antibiotics and MIC values determination

S. Tyski, W. Grzybowska (Warsaw, PL)

Objectives: In vitro bacterial susceptibility to antibiotics is tested in number of laboratories. However, quality of antimicrobial agents substances applied in Minimal Inhibitory Concentrations assays, especially – their biological activity, is often unknown. Since 2000 year, we have participated in several collaborative trials organised by European Directorate for the Quality of Medicines to assign potency values for candidate European Pharmacopoeia Chemical Reference Substances (CRS) and WHO International Standard used for the microbiological assays of antibiotics. These standards are also the best substances for MIC values determination.

Methods: The following antimicrobial agents were tested: erythromycin, nystatin, colistin, amphotericin B, spiramycin, bacitracin, and rifamycin. The assay was performed as described in Ph. Eur., using diffusion or turbidimetric methods and standard bacterial strains from ATCC recommended by Ph. Eur. for particular agent. Statistical analysis of results was performed with the usage of CombiStas programme.

Results: Erythromycin: 7 labs participated, obtained by us weighted combined estimate was 948 IU/mg (trial established potency = 960 IU/mg. Nystatin: three CRS batches were analysed, obtained by us results (6041, 5446, 5963 IU/mg), respectively corresponded to trials established potency (6030, 5600, 5710 IU/mg). Colistin: 6 labs participated, obtained by us weighted combined estimate was 584143 IU/vial (trial established potency = 580935 IU/vial. Amphotericin B: three CRS batches were analysed, obtained results (993, 987, 990 IU/mg), respectively corresponded to trials established potency (990, 960, 944 IU/mg). Spiramycin: 7 labs participated, obtained by us weighted combined estimate was 4540 IU/mg (trial established potency = 4530 IU/mg). Bacitracin: 7 labs participated, obtained by us weighted combined estimate was 63.1 IU/mg (trial established potency = 62.9 IU/mg). Rifamycin: diffusion method – 6 lab. participated, obtained by us weighted combined estimate was 857 IU/mg (trial established potency = 856 IU/mg; turbidimetric method – 4 labs participated, obtained by us weighted combined estimate was 849 IU/mg (trial established potency = 856 IU/mg).

Conclusions: Participation in collaborative trials showed, that results obtained in our lab – member of OMCL Network, are very good quality

and allowed to establish antimicrobial potency of several reference substances suitable for the MIC values determination.

P610 Tigecycline – in vitro susceptibility of anaerobic bacteria

R. Mutters, H. Bykow, C. Nonnenmacher (Marburg, DE)

Objectives: To determine the in vitro susceptibility of anaerobic and selected mircoaerophilic bacterial species for tigecycline a new glycylcycline anibiotic. Additionally it should be examined if the test results are biased by the medium or the incubation time used.
Methods: Minimal inhibitory concentration (MIC) testing was performed for tigecycline with the epsilon test (Etest®, AB Biodisk, Sweden) as recommended by the manufacturer. Tigecycline stripes with a concentration gradient from 0.016 μg/ml to 256 μg/ml were used. As test media Columbia blood agar at pH 6.8, Columbia blood agar at pH 7.3, Brucella agar and Schaedler agar were used. 297 isolates, representing 89 species were checked. Cultivation was conducted at 37ºC for 48 hrs and 72 hrs, respectively under anaerobic conditions or in the case of microaerophilic bacteria under mircroaerophilic conditions.
Results: All tested species exhibited low MIC values and could be identified as susceptible. But denpendency from the chosen media and growth conditions could be demonstrated. Comparable results were observed with Schaedler agar and Columbia blood agar at pH 7.3. Lowering the pH value of the Columbia blood agar to 6.8 led to different MIC values, Brucella agar again exhibited different MIC values compared with the other media. A reduction of the incubation time from 72hrs to 48hrs resulted in poor growth for several of the fastidioud species and in minor MIC values.
Conclusion: It could be shwon that the results of tigecycline susceptibility testing of anaerobic bacteria are dependent from the solid growth medium, the pH value and the incubation time. Because of the stability and comparibility of the results with Schaedler agar and Columbia blood agar at pH 7.3 it can be recommended to test tigecycline susceptibility on solid agar media at 37ºC with an incubation time of 72hrs, preferably on Schaedler agar. Because of the low MIC values determined for all isolates tigecycline appears to be a promising new agent for the treatment of infections caused by anaerobic bacteria.

P611 Activity of 5 antibiotics including tigecycline and meropenem against anaerobic bacteria: a French multicentre study

L. Dubreuil, L. Calvet, C. Soussy, C. Lascols, C. Muller-Serieys, H. Marchandin, H. Jean-Pierre (Lille, Créteil, Paris, Montpellier, FR)

Objectives: The study was deigned to evaluate the activity of tigecycline (TGC), meropenem (MPM), piperacillin–tazobactam (PTZ), metronidazole (MTZ) and clindamycin (CM) against 155 anaerobic bacteria during a survey carried out in 2007 in 4 French university hospitals.
Methods: MIC were determined using E test strips on Brucella blood agar (inoculum McFarland 1).
Results: See the table.

Microorganisms	N	TIG			MERO			PipTaz			METRO			CLIN		
		MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S
B. fragilis	62	0.19	0.5	98.3	0.25	0.75	98.3	0.38	2	98.3	0.125	0.25	100	0.75	>256	75.8
Other *Bacteroides*	35	0.19	0.5	100	0.19	0.5	100	0.75	8	97.1	0.25	0.5	100	2	>256	51.4
B. fragilis group	97	0.19	0.5	99	0.19	0.75	99	0.5	2	98	0.19	0.5	100	0.75	>256	61.8
Prevotella spp.	23	0.09	0.19	100	0.19	0.25	100	1	3	100	0.25	0.5	100	0.75	64	69.6

N: Number of tested isolates; TIG, tigecycline; MERO, meropenem; PipTaz, piperacillin + Tazobactam; METRO, metronidazole; CLIN, Clindamycin; %S: Percentage of susceptible strains; GPAC: Gram-positive anaerobic cocci.

Conclusions: TGC was the most potent agent against all Gram-positive anaerobes (MIC⩽ 0.5 mg/L). At least 97% of all anaerobic bacteria were inhibited by TGC, MPM, and PTZ. The clindamycin resistance rate remained high (>40%).

P612 Comparative activity of meropenem, imipenem and piperacillin / tazobactam against 1118 bacteria involved in hospital infections: a French multicentre study

M.L. Joly-Guillou, J.D. Cavallo, M. Chomarat, L. Dubreuil, J. Maugein, C. Muller-Serieys, M. Roussel-Delvallez, C. Soufflet (Angers, Saint Mande, Lyon, Lille, Bordeaux, Paris, FR)

Objective: This study was designed to evaluate the activity of meropenem (MPM), against 1118 non repetitive strains isolated from bacteraemia (55%), pneumonia (29%), peritonitis (12%) and wounds infections (3%), during a survey carried out in 15 French community and university hospitals, in 2006. Susceptibility tests and Minimum Inhibitory Concentrations (MICs) of meropenem (MPM), imipenem (IPM) and piperacillin plus tazobactam (PTZ) were determined by Etest® method (ET) in each centre. Disc diffusion test for MPM and MICs by the agar dilution method (AD) for MPM, IPM and PTZ were determined in specific centres for *E. coli* (EC), others enterobacteriaceae (EB), *Pseudomonas aeruginosa* (PA), aerobic Gram-negative bacilli (AE), *Acinetobacter* (AB), meticillin susceptible *Staphylococcus aureus* (MSSA) and coagulase-negative staphylococci (MSCNS) *Streptococcus pneumoniae* (SP) and anaerobes (AN).
Results: MICs obtained by AD are listed in the table.

	n	MPM			IPM			PTZ		
		%S	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}
EC	149	100	<0.016	<0.016	100	0.05	0.08	90	1.5	8
EB	149	99	0.019	0.05	99	0.11	0.87	85	1.64	14.8
PA	126	95	0.37	3.1	83	1.22	9.1	90	4.5	16
AB	79	98	0.46	1.35	97	0.33	0.96	42	1.41	123
AE	36	83	1	227	83	0.95	227	90	2.5	884
MSSA	145	100	0.09	0.12	100	0.032	0.046	100	0.96	1.84
MSCNS	137	100	0.06	1.1	100	0.013	0.09	100	0.43	0.85
SP	136	100	0.016	0.22	100	<0.016	0.1	100	0.14	3.3
AN	138	100	<0.015	0.5	99	0.048	0.5	92	0.5	16

MIC: Minimum inhibitory concentration; %S: percentage of susceptibility; n: number of tested isolates.

Conclusions: Compared to IPM, MPM displays lower MICs against EB, EC and PA. Except for AE, MICs90 of carbapenems are <4mg/l. Against AB, carbapenems display similar MICs; Compared to carbapenems, PTZ is less active against EB and AB but not PA. Some discrepancies were noted between MICs realised by ET in each centre and MICs realised by AD in specific centre. Especially for aerobics, MICs by ET were frequently higher than MICs by AD.

P613 In vitro activity of ceftobiprole against select Gram-positive and Gram-negative pathogens isolated from Europe in 2006–2007

M. Torres, D. Draghi, N. Brown, C. Thornsberry, D. Sahm, C. Pillar (Herndon, US)

Objective: Ceftobiprole (BPR) is a pyrrolidinone-3-ylidene-methyl cephalosporin with activity against a broad spectrum of clinically relevant pathogens, including meticillin-resistant *S. aureus* (MRSA). BPR is intended for use in hospitals against infections where resistant Gram-positive (GP) and Gram-negative (GN) bacteria, particularly MRSA, are suspected. As such, BPR is currently being developed to treat hospital-acquired pneumonia (HAP) and complicated skin and skin structure infections (cSSSI). The current surveillance initiative assessed the in vitro activity of BPR and comparator agents against GP and GN European (EU) clinical isolates from the past year.
Methods: During 2006 and 2007, GP (*S. aureus* [SA], coagulase-negative staphylococci [CoNS], and *S. pneumoniae* [SP]) and GN (Enterobacteriaceae [EN] and *P. aeruginosa* [PA]) clinical isolates were collected from 28 laboratories in 11 EU countries. All isolates were centrally tested by broth microdilution at Eurofins Medinet, Inc. (CLSI; M7–A7).

Results: Against the tested SA, the MICs of BPR were similar to those of vancomycin and linezolid by MIC90 of 1 mg/L and 2 mg/L, respectively. BPR MICs against MRSA were ⩽ 2 mg/L with the exception of 1.3% of MRSA isolates which had BPR MICs of 4 mg/L. Against EN and PA, BPR was similar to cefepime (FEP) by both MIC50/MIC90 (FEP: 0.06/4 mg/L for EN and 4/16 mg/L for PA).

Organism	Phenotype	Total n	BPR MIC (mg/L)			
			Range	Mode	MIC_{50}	MIC_{90}
SA	All	1,010	⩽0.12–4	1	0.5	2
	MSSA	272	⩽0.12–2	0.25	0.25	0.5
	MRSA	738	⩽0.12–4	1	1	2
CoNS	All	378	⩽0.12–4	1	0.5	2
	MS CoNS	114	⩽0.12–1	⩽0.12	⩽0.12	0.25
	MR CoNS	264	⩽0.12–4	1	1	2
SP	All	432	⩽0.002–0.5	0.008	0.008	0.25
	PEN S	335	⩽0.002–0.06	0.008	0.008	0.015
	PEN NS	97	0.004–0.5	0.25	0.25	0.5
EN	All	1,912	⩽0.015–>32	0.03	0.03	16
	CAZ S	1,656	⩽0.015–>32	0.03	0.03	0.12
	CAZ NS	256	0.03–>32	>32	32	>32
PA	All	533	0.06–>32	2	4	16
	CAZ S	421	0.06–>32	2	2	8
	CAZ NS	112	2–>32	>32	16	>32

PEN: penicillin; CAZ: ceftazidime; S: susceptible; NS: non-susceptible.

Conclusion: BPR had potent in vitro activity against the tested GP pathogens, regardless of resistance to meticillin or PEN. BPR was comparable to FEP against both CAZ S and CAZ NS of EN and PA, though MICs of both FEP and BPR were elevated against the CAZ NS isolates. These results show the potential of BPR for the treatment of HAP and cSSSIs. As BPR is intended for use in hospitals where resistance is common, continued surveillance of BPR activity against target pathogens is warranted.

P614 In vitro activity of a mixture of mustard oils (isothiocyanates) against antimicrobial and multidrug-resistant bacteria

A. Conrad, D. Bauer, T. Nobis, H. Richter, I. Engels, D. Jonas, U. Frank (Freiburg, DE)

Objectives: A herbal native preparation containing Tropaeoli majoris herba (nasturtium = N) and Armoraciae rusticanae radix (horseradish = H; Angocin® Anti-Infekt N, Repha GmbH, Germany) may be used for treatment of upper respiratory (URTI) and urinary tract infections (UTI). The preparation's antimicrobial efficacy is based on mustard oils (isothiocyanates = ITC), which are cleaved from glucosinolates after oral intake: benzyl-ITC from N, and allyl and phenylethyl-ITC from H. The objective was to assess the antimicrobial activity of a mixture of ITC against antimicrobial and multi-drug resistant bacteria.

Methods: Agar-dilution susceptibility testing was performed. ITC were mixed according to the proportion within the preparation by adding 50% (v/v) benzyl-ITC, 37.9% allyl-ITC, and 12.1% phenylethyl-ITC (all Fluka, Germany). The oil-mixture was dissolved in tryptic soy broth containing 8% Tween 80. Serial dilutions were performed and the mixture was added to Mueller Hinton agar just before casting in order to obtain concentrations ranging from 1% to 0.001%. Bacterial species were tested by use of a multi-point-inoculator (48 isolates in duplicates). Different bacterial species originated from a German surveillance project on antimicrobial resistance and included ESBL-producing *Escherichia coli* (n = 49), ciprofloxacin resistant *E. coli* (53), ESBL-producing *Klebsiella pneumoniae* (49), imipenem, ceftazidime and multi-drug resistant *Pseudomonas aeruginosa* (50), penicillin and macrolide resistant and intermediate resistant *Streptococcus pneumoniae* (43), meticillin resistant *Staphylococcus aureus* (48), vancomycin resistant *Enterococcus faecium* (50). After incubation for 24h at 37ºC, minimum inhibitory concentrations (MIC) were assessed, followed by subculturing to determine minimum bactericidal concentrations (MBC).

Results: MIC90 (% v/v) / MBC90 (% v/v): ESBL-producing *E. coli* 0.015/0.125, ciprofloxacin resistant *E. coli* 0.03/0.25, ESBL-producing *K. pneumoniae* 0.125/0.125, imipenem, ceftazidime and multi-drug resistant *P. aeruginosa* 0.03/0.06, penicillin and macrolide resistant and intermediate resistant *S. pneumoniae* 0.015/0.03, meticillin resistant *S. aureus* 0.004/0.5, vancomycin resistant *E. faecium* 0.015/>1.

Conclusion: The mixture of ITC displays broad activitiy against various antimicrobial and multi-drug resistant bacteria.

Extended-spectrum β-lactamases – Part 1

P615 Increasing number of ESBL-producing *Escherichia coli* during the last three years in Stockholm – A challenge for the clinical laboratory

A. Iversen, M. Andersson, M. Vondracek, C.G. Giske (Stockholm, SE)

Objectives: This study aimed at describing the epidemiologic situation of ESBL-producing *Escherichia coli* (ESBL-EC) in the Stockholm area during 2005 to 2007. The PhenePlate System (PhP) was validated as a screening method used for epidemiological typing of all ESBL-EC isolates and genotypic characterisation of the phylogenetic subgroups of the CTX-M β-lactamase was performed in parallel.

Methods: Clinical isolates of ESBL-EC for the years 2005 (n = 217), 2006 (n = 315) and 2007 (until September, n = 290) were epidemiological typed with the PhP biochemical typing system for *E. coli*. The global congruence between PhP-typing and pulsed-field gel electrophoretic (PFGE) patterns on XbaI digested DNA was examined for a subset of the isolates (n = 56) by the Comparing Partitions computer software. Unique PhP and PFGE-types were defined as isolates with similarity indices above 0.96 and 0.85 (Dice coefficient), respectively. Index of diversity was determined by Simpson index, while the Wallace coefficient was used to evaluate global agreement between the two typing methods.

Results: A steady increase in the prevalence of ESBL-EC for the years 2005–2007 was observed, while the total number of susceptibility tested isolates between the years was comparable. A tendency towards increased multi-resistance was noted. Using the PhP System 28 major clusters (⩾5 isolates of the same PhP-type) were found and two of these clusters have so far been confirmed with PFGE. In the subset of isolates subjected to parallel evaluation of PhP and PFGE greater discriminatory power was observed for PFGE, although not statistically significant. The Wallace coefficient showed that two strains belonging to the same cluster by PFGE had about 83% chance of having the same PhP-type, while conversely strains belonging to the same PhP-type had 74% chance of having the same PFGE-type.

Conclusion: Efficient epidemiological typing of ESBL isolates within a reasonable time-span is of great importance to clinical laboratories. For this purpose PhP, which is a less labour intensive method than PFGE was validated for epidemiological typing of ESBL-EC isolates. PhP-typing was found to be less discriminatory than PFGE, but can probably be used to exclude similarity by PFGE at the 85% cut-off level. Conversely, PhP-clusters should always be confirmed with PFGE. Genotyping revealed that CTX-M-15 and -14 are the most prevalent ESBL-variants in the Stockholm area.

P616 ESBL-producing Enterobacteriaceae in a County of Sweden during 2002–2007

Å. Östholm Balkhed, M. Tärnberg, A.V. Johansson, M. Nilsson, H-J. Monstein, L.E. Nilsson (Linköping, SE)

Objectives: To investigate the occurence of ESBL-producing Enterobacteriaceae in the County of Östergötland, Sweden.

Methods: From January 2002 until August 2007 ESBL-producing strains were collected in the county of Östergötland with 420 000 inhabitants. The ESBL phenotype was confirmed by Etest with ceftazidime, cefotaxime and cefepime, with and without clavulanic acid. PCR amplification was performed to screen for presence of CTX-M genes. CTX-M positive isolates were subjected to DNA sequencing.

Results: A total of 217 clinical isolates, 191 *Escherichia coli*, 24 *Klebsiella pneumoniae*, 1 *Shigella sonnei* and 1 *Citrobacter koseri*, with an ESBL phenotype was found. The isolates mainly came from the urinary tract but also from blood and other sources. Patients identified with ESBL-postive isolates were 6 in 2002 and increased to 39 in 2006. From January until the end of August 2007 32 patients were found. Onehundred ninety-three bacterial isolates were further investigated. The PCR revealed that among *E. coli* 66% belonged to CTX-M group 1, 32% consisted of CTX-M group 9 and more rare was CTX-M group 2. In *K. pneumoniae* 47% belonged to CTX-M group 1 and the other half was conferred to other enzymes. In *S. sonnei* CTX-M group 1 was found and in *C. koseri* CTX-M group 9 was detected. In 4 patients we found both ESBL-producing *E. coli* and *K. pneumoniae*. Eight patients had repeat isolates with ESBL-producing *E. coli* in urine specimens for more than 6 months.
Conclusions: Prevalence of ESBL in clinical specimens is still rare, less than 1%, in our region but the number of patients with ESBL positive isolates increases. CTX-M group 1 is the dominating enzyme group in both *E. coli* and *K. pneumoniae*.

P617 First clonal outbreak of a multi-resistant CTX-M-15 producing *Klebsiella pneumoniae* in Denmark

D.S. Hansen, D.S. Christiansen, E.M. Nielsen, F. Hansen, L. Nielsen, B. Bruun (Hillerød, Copenhagen, DK)

Objectives: Increasing frequency of extended spectrum bete-lactamases (ESBL) producing organisms have been reported worldwide, causing major problems in treatment of serious infections, limiting antibiotic therapy to broad-spectrum antibiotics such as carbapenems.
Until the mid-nineties TEM and SHV and their derivates were the predominant β-lactamases, but recently a new group, the CTX-M β-lactamases, have emerged and now seem to be the most widespread ESBLs in many countries. Since the first case reports in *E. coli* from Japan in 1986, the CTX-M enzymes have disseminated worldwide, especially among Enterobacteriaceae.
The rate of antibiotic resistance in the Nordic countries has generally been low; however, recently outbreaks of ESBL-producing organisms have been described from both Norway and Sweden. We here describe the first clonal outbreak of a multi-resistant CTX-M-15 producing *Klebsiella pneumoniae* in Denmark.
Methods: Antibiotic susceptibility testing was done by disc diffusion (Oxoid disc, Isosensitest agar, SRGA breakpoints). ESBL-production was screened for using a cefpodoxime disc; phenotypic confirmation was by the Combi-disc method using Rosco tablets (ceftazidime and cefotaxime +/− clavulanic acid). Identification of ESBL type was done by PCR and sequencing, typing by PFGE using XbaI.
Results: In April 2007 we became aware of two patients with a multi-resistant ESBL-producing *K. pneumoniae* in a medical ward. The isolates were resistant to gentamicin, ciprofloxacin, cephalosporins, trimethoprim/sulfamethoxazole and piperacillin/tazobactam, but susceptible to meropenem and colistin. Soon thereafter we found more isolates, and a systematic screening of patients on the four involved wards, as well as a retrospective search in archives and freezers, identified a total of 36 patients colonised/infected with the strain. Six isolates dating back before the index cases were found, the earliest from January 2006. All isolates had the same or minor variation of the PFGE pattern.
Conclusions: This is the first report of clonal outbreak of a multi-resistant CTX-M-15 producing *K. pneumoniae* in Denmark. The length of time this strain has been able to survive and spread in the hospital environment fully underscores the potential of this and similar CTX-M producing strains to disseminate worldwide.

P618 Predominantly clonal transmission of CTX-M-1 harbouring *K. pneumoniae* in two wards

M. Kaase, A. Anders, S. Friedrich, G. Schieren, T. Förster, F. Szabados, T. Sakinc, B. Kleine, S.G. Gatermann (Bochum, DE)

Objectives: Resistance against third generation cephalosporins in *K. pneumoniae* is an increasing problem and is mainly due to extended spectrum β-lactamases (ESBL). A worldwide increase of CTX-M-type β-lactamases has been described in recent years but epidemiologic data from Germany are scarce.
Methods: From January 2006 to April 2007 we collected 38 non-copy isolates of *K. pneumoniae* with an ESBL phenotype from ward A (N = 29) and B (N = 9), located in different hospitals and representing different patient populations. Typing was performed by PFGE after enzymatic DNA macrorestriction with XbaI. PCR for TEM, SHV and CTX-M was conducted in all isolates. In single representative isolates genes coding for CTX-M were sequenced. MICs of β-lactam-antibiotics were determined by Etest or microdilution, susceptibility testing for other antibiotic classes was done by agardiffusion.
Results: 15 and 3 isolates from ward A belonged to clone 1 and 2, respectively. 5 isolates from ward B (clone 3) had identical PFGE patterns. All isolates had an SHV β-lactamase as expected. TEM was found in 21 isolates, a CTX-M β-lactamase was found in 36 isolates. In 34 isolates, including all clone 1, clone 2 and clone 3 isolates, a CTX-M-1 group β-lactamase was found. A CTX-M-9 group β-lactamase was found in two isolates.
MIC50 was >256 mg/l for piperacillin, 8 mg/l for piperacillin/tazobactam, 6 mg/l for temocillin, >256 mg/l for cefotaxim and 128 mg/l for ceftazidim. Resistance rates against other antibiotic classes were 94.7% for ciprofloxacin, 78.9% for tobramycin, 34.2% for gentamicin, 26.3% for doxycyclin and 52.6% for sulfamethoxazol-trimethoprim.
Conclusion: Clonal transmission was the most important factor responsible for spread of CTX-M-1 group harbouring *K. pneumoniae* in both wards. Predominant clones were different in both locations highlighting the significance of local epidemiological studies. Temocillin and piperacillin/tazobactam retained good activity in vitro agains ESBL *K. pneumoniae* isolates in our area.

P619 Epidemiology and molecular screening of ESBL-producing Enterobacteriaceae in a Dutch hospital

E.J. van Hannen, C. van Oostveen, L. Kool, B.J.M. Vlaminckx (Nieuwegein, Utrecht, NL)

Objectives: Over the last five years, resistance against third-generation cephalosporins has increased exponentially in the Netherlands. Until 2002, ESBL-producing micro-organisms were virtually absent in our hospital. Nowadays approximately 6–7% of clinical *Escherichia coli*, *Enterobacter cloacae* and *Klebsiella pneumoniae* isolates carry plasmids encoding the ESBL phenotype.
In analogy to our MRSA policy, we actively search for ESBL positive micro-organisms to contain their further spread. To enable rapid screening, we developed a real time PCR test to detect the CTX-M gene in Enterobacteriaceae with an increased MIC to third-generation cephalosporins. Theoretically, the benefit of this molecular screening would be a two days shortening in the time needed to detect an ESBL.
Methods: We performed a retrospective analysis of the epidemiology of ESBL-producing *E. coli*, *E. cloacae* and *K. pneumoniae* strains in our hospital. Subsequently, all ESBL-producing strains were screened for the presence of TEM, SHV and CTX-M genes by a classic multiplex PCR. A real-time PCR, detecting all 5 CTX-M groups, was then developed and used to enable rapid, weekly screening for ESBLs on our intensive care unit (ICU).
Results: In 2002, less than 1% of our clinical *E. coli* isolates was ESBL positive. This number rose steadily to 6% in 2007. For *E. cloacae* and *K. pneumoniae*, these numbers were 1.3% in 2002 and 7% in 2007 and 1% in 2002 and 5.8% in 2002, respectively.

Molecular analyses showed that approximately 60% of the ESBL-producing strains in our hospital carried the CTX-M gene, with the relative contribution of CTX-M increasing over time. We therefore developed a real-time PCR to detect the presence of this gene. This PCR was then used in an ongoing weekly screening for ESBL-producing Enterobacteriaceae in our ICU.
Conclusion: The occurrence of ESBL-producing enterobacteriaceae in our hospital has increased from approximately 1% in 2002 to 7% in 2007. Sixty percent of these bacteria carried the CTX-M gene. Molecular screening for this gene in clinical isolates from the ICU speeds up the detection of more than 60% of ESBL-producing enterobacteriaceae in our hospital with two days. Parameters to evaluate the additional value of this newly developed strategy are the reduction of secundary cases and the time needed to control an ESBL outbreak.

P620 Extended-spectrum β-lactamases in the Czech Republic

J. Hrabak, J. Empel, T. Bergerova, P. Urbaskova, M. Gniadkowski (Plzen, CZ; Warsaw, PL; Prague, CZ)

Objectives: Extended-spectrum β-lactamases (ESBLs) are one of the most important mechanisms of resistance to newer generation β-lactams in Gram-negative bacteria. In the Czech Republic, there has not been done yet any molecular epidemiology study on ESBL-producing organisms. The objective of this analysis is to characterise ESBLs and ESBL producers in one of the biggest Czech hospitals, the University Hospital in Plzen.
Methods: In 2006, a 1-month survey of ESBL-producing bacteria was performed. Twenty-four non-repetitive isolates of *Klebsiella pneumoniae* (n = 10), *Escherichia coli* (n = 9), *Providencia stuartii* (n = 3), *Enterobacter cloacae* (n = 1) and *Proteus mirabilis* (n = 1) were collected. The isolates were typed by RAPD and used in conjugative transfer experiments for ESBL-mediated resistance. ESBLs were characterised by isoelectric focusing, bioassay, and PCR and sequencing of bla genes.
Results: At least seven different ESBL variants were identified in the isolates. SHV enzymes dominated in *K. pneumoniae* (SHV-5, SHV-12 and probably SHV-2), whereas CTX-M β-lactamases, mostly CTX-M-15, were predominant among *E. coli*. The CTX-M-15-encoding gene was preceded by the ISEcp1 element at a distance of 48 bp. TEM-type ESBLs were produced by the remaining strains; TEM-92 by all *P. stuartii* isolates, and TEM-132 – by *E. cloacae*. Genes coding for SHV-5, SHV-12, CTX-M-15 and TEM-132 were located on conjugative plasmids. A significant number of isolates (*K. pneumoniae* SHV-5, *E. coli* CTX-M-15 and *P. stuartii* TEM-92) appeared owing to clonal dissemination of producer strains.
Conclusions: This work showed a high diversity of ESBL variants in the Czech hospital, which included both globally-disseminated and more locale-specific enzymes.
This work was partially supported by a research project MSM 0021620819.

P621 Monitoring, epidemiology and molecular analysis of extended-spectrum β-lactamase producing *Klebsiella pneumoniae* strains isolated at a large hospital in Budapest during a four-month period

T. Tirczka, Á. Tóth, I. Damjanova, E. Szilágyi, J. Korom, F. Bukovszki (Budapest, HU)

Objectives: Comprehensive multilevel investigation of outbreaks caused by extended-spectrum β-lactamase producing *Klebsiella pneumoniae* (ESBL-KP) in a large tertiary hospital in Budapest during period of four months.
Methods: During the study period ESBL-KP strains were recovered from 18 different hospital wards. Altogether 270 samples were examined, of these 48 environmental and 163 patient and staff samples, respectively. Antimicrobial susceptibility testing was performed by disk diffusion method according to the recommendations of the CLSI. On the basis of preliminary phage typing results ESBL-KP isolates were tested by PFGE. Molecular typing was performed by SHV, CTX-M and TEM PCRs, plasmid profile analysis, transfer of resistance determinants and sequencing of resistance genes.
Results: 132 ESBL-producing clinical isolates of Gram-negative pathogens (GNPs) were collected from October 2006 to January 2007 from 82 patients and hospital staff as follow: *Klebsiella pneumoniae* (n = 86), *Escherichia coli* (EC) (n = 35) and other species (n = 11). One of 48 enviromental samples was positive for ESBL-KP.
70% of samples recovered from the Neonatal Intensive Care Unit (NICU), 50% of samples from the Neurosurgery and the Chronic Internal Medicine Ward (CIMW), respectively, and 30% of samples from the Intensive Care Unit (ICU) proved ESBL-producers.
The molecular characterisation of ESBL-KP strains isolated from the NICU showed that all of them belonged to the same pulsotype (X clone) and harboured blaSHV-5 gene on plasmid of app. 90 kb.
PFGE analysis of ESBL-KP strains isolated from 9 adult wards revealed parallel existence of three different genetic clones: the Hungarian Epidemic Clone (HEC, pulsotype N), the Epidemic clone III (EC III, pulsotype S) and the clone L. All of them harboured blaCTX-M-15 on large plasmids ranged from 50 to 90 kb.
Conclusion: Three parallel outbreaks caused by ESBL-KP were detected in the NICU, the ICU and the Neurosurgery from October to December of 2006. Additionally high colonisation rate (32%) with ESBL-KP was found in the CIMW.

P622 Outbreak of CTX-M extended-spectrum β-lactamase-producing *Klebsiella pneumoniae* in a large general hospital Trust in the UK

L. Xu, S. Shabir, K. Hardy, K. Nye, P. Hawkey, J. Stone (Birmingham, Cheltenham, UK)

Objectives: The aim of this study was to investigate the molecular epidemiology of an outbreak of ESBL-producing *K. pneumoniae* in a large general hospital Trust in the UK.
Methods: Isolation of ESBL-producing Enterobacteriaceae mainly from catheter urines increased from approximately 5 to 40 isolates per month at a large general NHS Trust Hospital. All isolates recovered over a three month period were screened for susceptibility to cefpodoxime by the BSAC disc diffusion method and ESBL production confirmed using cefpodoxime, cefpirome and ceftazidime with and without clavulanate. Eighty-one of these outbreak isolates were subjected to multiplex PCR to detect all blaCTX-M genes. Clonal relationship was studied by PFGE.
Results: The eighty-one ESBL-producing isolates included 62 *K. pneumoniae* and 19 *E. coli*; 60 isolates (74.1%) from the hospital and 21 isolates (25.9%) from the community. More than 95% of these clinical isolates were recovered from urinary specimens. Multiplex PCR screening identified a blaCTX-M gene in 55/62 *K. pneumoniae* isolates (88.7%) and all of them harboured a blaCTX-M group 1. Characterisation of the regions surrounding the blaCTX-M showed that all isolates carried ISEcp1 upstream from the blaCTX-M and 35 had a IS26 element inserted into ISEcp1. PFGE analysis confirmed that all 55 blaCTX-M positive *K. pneumoniae* isolates belonged to a single epidemic clone (>87% similarity), designated strain GK.
Conclusion: This is the first well documented report of a large outbreak of CTX-M-producing *K. pneumoniae* in a major hospital Trust in the UK. We demonstrated that the dissemination of CTX-M-producing strains of *K. pneumoniae* both in the hospital and the community is due mainly to the diffusion of a single epidemic clone. The outbreak highlights the epidemic potential of CTX-M-producing *K. pneumoniae* and the importance of strengthening infection control measures. Further genotyping of CTX-M producing isolates by DHPLC and sequencing will be undertaken and extensive investigations to determine the source of the outbreak are continuing.

P623 **Trends in extendeds-spectrum β-lactamase *Klebsiella pneumoniae* in a tertiary Spanish hospital (1993–2006)**

C. Ardanuy, M. Dominguez, L. Calatayud, F. Tubau, J. Ayats, C. Peña, M. Pujol, R. Martín, J. Liñares (L'Hospitalet de Llobregat, ES)

Objective: The objective of this study was to characterise the ESBL-*K. pneumoniae* strains isolated in a tertiary hospital during a 14-year period (1993–2006).

Methods: Screening of ESBL was performed by double disk synergy test. All available *K. pneumoniae* strains were typed by PFGE (XbaI). The ESBL characterisation was performed by isoelectric focusing of betalactamases and by PCR of ESBL family. All ESBLs genes of strains causing nosocomial outbreaks were sequenced.

Results: During the study period, *K. pneumoniae* was isolated from clinical samples of 4925 patients admitted to our hospital. Three hundred and seventy three (7.6%) *K. pneumoniae* carried an ESBL, and the majority of them (197/373, 53%) were isolated from ICU patients. Isolates from 290 patients were available for further studies. Sixty-seven different PFGE patterns were found among the 290 isolates studied. Two major outbreaks were observed throughout the study period. The first of them, involving 150 patients, occurred between 1993–1995 and was due to the spread of strains of Kp1 clone. The majority (85%) of Kp1 isolates produced one ESBL and 15% two ESBLs. By sequencing 34% of ESBL-Kp1 were identified as SHV-2 (pI 7.6), 51% as SHV-5 (pI 8.2) and 15% as SHV-2 plus SHV-5 (pIs 7.6 and 8.2 respectively). The second outbreak was due to Kp29 clone and accounted for 53 patients. This epidemic Kp29 strain produced an SHV-2 betalactamase (pI 7.6). The majority (66%) of Kp29 isolates were detected between September 1999 and November 2000. Another eight clusters of ESBL-*K. pneumoniae* (SHV-family) involving 2 to 7 patients each were detected throughout the study period. During 1999–2006 period, 8 unrelated *K. pneumoniae* producing CTX-M-9 family were detected. Only 2 unrelated strains harbouring a TEM-family ESBLs were detected in 1995 and 2003, respectively.

Conclusion: Although the global prevalence of ESBL-*K. pneumoniae* infections in our institution was 7.6%, the annual frequency ranged from 3% to 18%. Two major outbreaks were associated with the dissemination of epidemic strains producing SHV-2 and/or SHV-5 ESBLs. Isolation of strains producing CTX-M-9 or TEM families of ESBLs is infrequent among *K. pneumoniae*.

P624 **Extended- and broad-spectrum β-lactamase-producing *Klebsiella pneumoniae* isolates in 17 clinical health institutions in Portugal participating in the ARSIP Program**

N. Mendonça, E. Ferreira, D. Louro, M. Caniça for the Antibiotic Resistance Surveillance Programme in Portugal

Objectives: We report phenotypic and genotypic analysis of clinical isolates of *K. pneumoniae* of both community and nosocomial origin recovered in various hospitals and public health institutions of Portugal.

Methods: A total of 212 *K. pneumoniae* strains isolated over six consecutive months of 1999 in 14 hospitals and 3 other public health institutions were tested for susceptibility to 23 antibiotics by using CLSI guidelines. New enzymes and respective transconjugants were also tested for susceptibility. PCR and sequencing were used to screen and identify blaTEM, blaSHV, blaOXA, ampC and blaCTX-M genes. Biochemical characterisation was performed by isoelectric focusing. Genetic relatedness of 131 isolates was studied by PFGE analysis.

Results: Mostly strains were from women, patients >60 years-old and urinary tract infections; 86% were resistant to ampicillin, 29% to trimetoprim-sulphametoxazole, 16% to aminoglycosides and 2% to fluoroquinolones; 16% were multidrugresistant and 15% expressed an ESBL phenotype, although only 13% (27/212) of these were confirmed by genotyping. Indeed, molecular methods identified 11 strains possessing blaESBL-SHV genes (blaSHV-2A, blaSHV-5, blaSHV-12 and blaSHV-55), 9 with blaESBL-TEM (blaTEM-3, blaTEM-10 and blaTEM-24) and 7 with blaGES-1, encoding ESBL enzymes; 9 with blaLEN, 8 with blaOKP, and 160 with blaSHV-1 and blaSHV-type encoding non-ESBL enzymes; and 4 strains hyperexpressing blaSHV-1 genes, that expressed an ESBL phenotype. Only IEF method identified the expression of the blaSHV-type gene in 4 strains. Overall, we detected 26 new enzymes: SHV-60 to SHV-62, SHV-73 to SHV-83, LEN-18 to LEN-21, LEN-23, OKP-A-12 and OKP-B-15 to OKP-B-20. Twenty additional strains isolated during a second period, between March and November 2006, in three of the 14 participating hospitals, contained ESBL-encoding genes whereas none of the strains isolated in the same hospitals in 1999 carried such genes: blaSHV-5, blaSHV12, blaTEM-10, blaTEM-52, blaCTX-M-15, blaCTX-M-32 and blaCTX-M-61. The PFGE analysis showed that strains were diverse, and 25 clusters were defined, the largest including 14 strains of different biological origins, 6 of which expressed GES-1 enzymes. No dominant epidemic clone was detected.

Conclusion: We described the expansion of β-lactamases produced by *K. pneumoniae* in 3 large regions in Portugal, providing evidence that the genotypes of *K. pneumoniae* strains in community and hospital environments is changing.

P625 **Spread of CTX-M extended-spectrum β-lactamases among *Escherichia coli* and *Klebsiella pneumoniae* isolates in Italian long-term care facilities: results of the first nationwide prevalence study**

L. Pagani, R. Migliavacca, M. Spalla, D. Saviane, L. Regattin, V. Botti, C. De Luca, A. Raglio, A. Goglio, S. Brusaferro (Pavia, Udine, Bergamo, IT)

Objectives: In the present century CTX-M Extended-Spectrum Beta-Lactamases (ESBLs) have become predominant mainly in *E. coli*, and the producers are increasingly isolated from community patients. Over 60 different CTX-M-type enzymes have been identified from around the world. Reports of Italian isolates with CTX-M ESBLs only began to appear in 2003. The objective of this study was to evaluate the diffusion of CTX-M type β-lactamases among *E. coli* and *K. pneumoniae* clinical isolates recovered from Long-Term Care Facilities (LTCFs) residents across Italy.

Methods: All catheterised inpatients at the 37 facilities involved in the study were surveyed in the same day between Sept. 2006 and Jan. 2007. Susceptibility testing of urinary isolates was performed with VITEK 2 System (Bio-Mérieux). All isolates identified as ESBL producers according to CLSI criteria were tested at first for blaCTX-M alleles by PCR with universal primers. ESBL-CTX-M producers detected by phenotypic and genotypic methods were then investigated by using specific primers for various blaCTX-M groups. The clonal relationships between epidemiologically relevant *E. coli* and *K. pneumoniae* strains were evaluated by PFGE.

Results: A total of 496 Enterobacteriaceae isolates were recovered. The overall ESBL producers rate was 39.7%. All isolates were characterised by co-resistances but all retained susceptibility to carbapenems.

The prevalence rates of *E. coli*, the most frequent uropathogen, and of *K. pneumoniae* were 40.5% and 8.5% respectively. Seventy-two *E. coli* (35.8%) and ten *K. pneumoniae* (23.8%) produced ESBLs, with 75% and 60% respectively producing CTX-M enzymes. CTX-M-1-group ESBLs were the most prevalent in *E. coli* (49/54 strains) but CTX-M-9-group variants were also identified (5/54 strains). *K. pneumoniae* isolates produced CTX-M-1 group enzymes exclusively. The five *E. coli* CTX-M-9-type producers were from 4 LTCFs: two located in Southern Italy and the others in Northern Italy. *E. coli* CTX-M-9-type producers were clustered in three clonal lineages, one of which responsible for an epidemic in a LTCF in Catania.

Conclusions: Our data confirm that LTCFs are reservoirs of MDR pathogens and that CTX-M-type ESBLs are widespread also in these settings. The overall CTX-M producers rate in LTCFs is higher than that reported in the second Italian nationwide survey (2003) for isolates from acute-care hospitals. Our results document the dissemination of CTX-M-9-type genes also in Italian area.

P626 Molecular types of extended-spectrum β-lactamases in *Escherichia coli* strains isolated from community-acquired urinary tract infections in Turkey

H. Arslan, O. Kurt Azap, S. Serin Senger, F. Timurkaynak (Ankara, TR)

Background: Extended-spectrum β-lactamase (ESBL)-producing *Escherichia coli* have been increasingly recognised in the community. The aim of this study was to determine the prevalence of CTX-M, SHV, and TEM types of ESBLs for community-onset ESBL-producing *E. coli* in urinary tract infections (UTIs).

Methods: ESBL-producing *E. coli* strains isolated from adults with community-onset UTIs during two distinct periods in 2004 and 2006 were collected from four centres in different cities of Turkey. The presence of ESBL was established on the basis of CLSI criteria and confirmatory tests. Polymerase chain reaction and DNA sequencing were used to characterise the blaTEM, blaCTX-M and blaSHV genes.

Results: We analysed 54 *E. coli* isolates (18 isolates from 2004 and 36 from 2006–2007). The prevalence of CTX-M, SHV, and TEM were 94.4% (51), 9.3% (5), and 42.6% (23) respectively. Sequence analysis of the blaCTX-M containing isolates revealed that these isolates contained two different blaCTX-M, 2 (3.9%) with blaCTX-M-3, and 49 (96.1%) with blaCTX-M-15. We found 3 different ESBL blaSHV types: blaSHV-12, blaSHV-5, and blaSHV-2. There were 2 blaTEM-116 carrying isolates.

The two isolates carrying TEM-116 had also CTX-M-15, and they belonged to the 2006–2007 period. There were no other significant differences in the two periods regarding the ESBL types. In the table the distribution of the CTX-M, SHV, and TEM ESBL types is shown.

Table: The distribution of ESBL types among the isolates

ESBL types			Number of isolates		
TEM	SHV	CTX-M	2004	2006–07	Total
–	–	CTX-M-15	16	31	47
–	–	CTX-M-3	0	2	2
TEM-116	–	CTX-M-15	0	2	2
–	SHV-5	–	1	0	1
–	SHV-2	–	1	0	1
–	SHV-12	–	0	1	1
2	**3**	**51**	**18**	**36**	**54**

Conclusions: ESBL-producing *E. coli* in non-hospitalised patients seem to be emerging with various types and prevalence in different countries. Our study revealed dissemination of CTX-M type ESBL in *E. coli* strains isolated from community-acquired UTIs in Turkey. CTX-M-15 was the most common enzyme.

In this study in only two of the isolates we found ESBL-type TEM, and they were isolated in 2006. This may indicate that a novel ESBL type (TEM-116) has emerged. A close follow up whether this novel ESBL type disseminates would be appropriate. The coexistence of CTX-M-15 with ESBL-type TEM genes has been observed in two isolates, compatible with similar findings in recent studies.

P627 Rapid emergence and dissemination of blaCTX-M among Enterobacteriaceae in USA medical centres: report from the MYSTIC Program (2007)

M. Castanheira, R. Mendes, P. Rhomberg, L. Deshpande, R. Jones (North Liberty, US)

Objective: To characterise extended-spectrum β-lactamase (ESBL) and plasmid-mediated AmpC (pAmpC)-encoding genes among Enterobacteriaceae (ENT) isolates collected from USA medical centres, and to identify plasmid-mediated fluoroquinolone resistance (pFQ-R) encoding genes among ESBL-producing isolates.

Methods: 1,392 ENT isolates were collected from 15 USA medical centres through the MYSTIC Program during 2007 and tested by the CLSI broth microdilution method. ESBL-positive (clavulanate inhibited) strains were tested for the presence of PER, GES, VEB, CTX-M and OXA enzymes with a multiplex PCR approach. ESBL screen positive but not confirmed were screened for pAmpC genes. Isolates were also tested for qnr-type, qepA and aac(6′)-Ib-cr. Primers annealing on genetic structures flanking the resistance encoding genes were used to obtain complete DNA sequences. Amplicons were sequenced in both strands and results analysed.

Results: Among 70 (5.0% of the total) ENT isolates with an ESBL phenotype, blaCTX-M was detected in 28 (40.0%; 24 *E. coli*, 2 *K. pneumoniae*, 1 *P. vulgaris* and 1 *K. oxytoca*). CTX-M-15 (18 strains, 64.3%) and CTX-M-14 (9, 32.1%) were most prevalent; CTX-M-3 was observed in one strain (3.6%). These isolates were collected in 12 centres (80.0% of the participating sites). OXA-encoding genes with ESBL spectrums were identified in 10 isolates, one co-producing CTX-M. Five isolates harbored blaCMY-2 (4 *E. coli* and 1 *K. pneumoniae*), while 4 isolates carried blaFOX-5 (3 *K. pneumoniae* and 1 *K. oxytoca*). Nine ESBL-positive (12.9%) isolates carried qnr genes (2 qnrA, 6 qnrB and 1 qnrS). The qnr genes were found in one isolate carrying each of the β-lactamases: blaFOX-5, blaCMY-2, blaCTX-M-15, blaOXA-2 and blaOXA-10. Only one (3.6%) CTX-M-producing strain carried aac(6′)-Ib-cr. This isolate harbored blaOXA-10 and blaCTX-M-14. Meropenem was active against all blaCTX-M and ESBL-producing strains.

Conclusions: For over a decade CTX-M-producing isolates have been reported as the highly prevalent ESBL resistance mechanism in Europe and Asia. In contrast, these enzymes were considered unusual in the USA. In this 2007 collection of ENT from USA medical centres, at least 2 distinct CTX-M-type enzymes have disseminated among different species and institutions. In addition, the prevalence of pFQ-R encoding genes among β-lactamase-producing isolates was higher than that observed in ENT not carrying these resistance determinants.

P628 Occurrence of blaCTX-M genes in quinolone resistance Enterobacteriaceae isolates from Brazil

L.A.R. Minarini, N.A.C. Trevisani, A.L.C. Darini (Ribeirão Preto, BR)

Objectives: To determine the prevalence of plasmid-encoded extended-spectrum β-lactamases (ESBL) among a collection of quinolone resistance Enterobacteriaceae isolates recovered in a community setting from Brazil.

Methods: Two hundred fifty seven non-repetitive nalidixic-acid resistant enterobacterial isolates were collected in a private laboratory from January 2000 to May 2005. The production of ESBL was detected according to Clinical and Laboratory Standards Institute (CLSI) criteria. Beta-lactamase-encoding genes were detected by PCR using universal primers for the TEM, SHV, and CTX-M families. The ESBL isolates were tested for qnrA, qnrB, qnrS and aac(6′)-Ib-cr genes by PCR technique. Conjugation experiments were performed to determine whether the ESBL genes carrying plasmids were self-transferable. Hybridisation experiments were performed with a Southern transfer from recombinant and original plasmids harboring blaCTX-M. Genetic structures surrounding the blaCTX-M genes were analysed by PCR and the genetic relatedness of the isolates determined by pulsed-field gel electrophoresis.

Results: Twenty four (9.3%) ESBL-producing Enterobacteriaceae strains were isolated during the study period, 9 were *Escherichia coli*, 6 *K. pneumoniae*, 5 *Enterobacter cloacae*, 2 *Providencia stuartii*, 1 *Morganella morganii* and 1 *Citrobacter freundii*. PCR and DNA sequencing detected isolates harboring blaCTX-M-2 (n = 13), blaCTX-M-9 (n = 3), blaCTX-M-8 (n = 2), and blaSHV-5 (n = 6). The ESBL-positive isolates were also positive for the blaTEM-1 gene, except one *M. morganii* isolate. Plasmids harboring blaCTX-M were not transferable and ranged from 40 to 180 kb in size. One *K. pneumoniae* isolate co-harbored blaCTX-M-2 and qnrB2 gene and an *E. cloacae* isolate that was qnrA positive harbored blaSHV-5. However, ESBL and qnr genes were found in different plasmids. No aac(6′)-Ib-cr gene was found in ESBL isolates

studied. ISEcp1 was identified upstream of the blaCTX-M-9 and ISCR1 was found in isolates harboring blaCTX-M-2.

Conclusion: The results presented in this study provided additional data about the molecular epidemiology of plasmid-encoded ESBL determinants among enterobacterial isolates recovered in a Brazilian community setting. A large diversity of genotypes was circulating in the community, with a predominance of blaCTX-M-encoding non-conjugative plasmids. A low prevalence of Qnr determinants was found in ESBL-producing isolates recovered from Brazilian community.

P629 Phylogenetic groups of non-clonally related *Klebsiella pneumoniae* clinical isolates with and without extended-spectrum β-lactamases

A. Valverde, T.M. Coque, F. Baquero, R. Cantón (Madrid, ES)

Objectives: Phylogenetic groups of *Klebsiella pneumoniae* isolates have been associated with the presence of specific chromosomal β-lactamases and the environmental compartment origin. In this study the population structure and phylogenetic groups of different *K. pneumoniae* isolates with and without extended spectrum β-lactamases (ESBL) recovered from hospitalised and non-hospitalised patients were characterised.

Methods: A total of 102 non-clonally related *K. pneumoniae* strains recovered from 26 outpatients and 76 hospitalised patients were analysed. Isolates distribution was as follows: 66 ESBL-producing isolates (1989–2004) (10 blood, 28 urine, and 28 other samples) and 36 non-ESBL-producing isolates (2005–2007) (14 blood, and 22 urine). Clonal typing was established by XbaI-PFGE. Phylogenetic groups (KpI, KpII, and KpIII) were determined by PCR amplification of the gyrA gene and further analysis of the RFLP pattern obtained with HaeIII and TaqI (Brisse et al. CMI 2004; 10:942–5). Amplification of the chromosomal blaSHV, blaOKP and blaLEN genes was also performed. ESBL characterisation was established by PCR and further sequencing.

Results: Distribution of isolates between different phylogenetic groups was as follows: KpI (81/102), KpII (3/102) and KpIII (18/102). This distribution was not substantially affected when considered different sources and resistance patterns. Most of the susceptible isolates obtained from blood cultures belonged to KpI group (13/14) as well as those obtained from urine samples (18/22). The corresponding values for ESBL producers were as follows: (6/10) and (24/28), respectively. Nevertheless, a clear association was observed with CTX-M-10 producing isolates and KpIII-group ($p < 0.001$, Chi squared test), irrespective of clinical source and patients' origin. KpIII non-ESBL-producing isolates were recovered from outpatients. Most of the KpIII-isolates (15/18) were also positive for blaLEN.

Conclusions: KpI is the most prevalent phylogenetic group in *K. pneumoniae* isolates from clinical origin in both ESBL and non-ESBL producers. However, KpIII phylogenetic group, previously associated with environmental sources, was consistently linked with blaCTX-M-10 and chromosomal blaLEN gene. This association might reinforce the potential environmental origin of these ESBL-producing isolates.

P630 Prevalence of faecal carriage of ESBL-producing Enterobacteriaceae in patients with severe abdominal infections

M. Tärnberg, Å. Östholm Balkhed, H. Hanberger, A.V. Johansson, H.J. Monstein, M. Nilsson, L. Påhlman, L.E. Nilsson (Linköping, Uppsala, SE)

Objectives: A Swedish multi-centre study was carried out to determine the aerobic enteric faecal flora in patients with severe abdominal infections during hospitalisation, with a special emphasis on carriage of Enterobacteriaceae producing extended spectrum β-lactamases (ESBL).

Method: Rectal swabs were obtained at admission to hospital, during antibiotic treatment and at least 48h after end of antibiotic treatment. Samples were also obtained during operation and at clinical indications. Cultures were performed on chromogenic agar with antibiotic discs. Antibiotic susceptibility testing was performed using the disk diffusion method according to the Swedish Reference Group for Antibiotics. ESBL-phenotype was confirmed by Etest with cefotaxime, ceftazidime and cefepime, with and without clavulanic acid. The isolates were subjected to PCR for screening of CTX-M genes, using universal CTX-M primers, followed by DNA-sequencing.

Results: Of 129 analysed patients, 14 had isolates of Enterobacteriaceae with an ESBL-phenotype. Twelve patients were colonised by only one species with ESBL-phenotype, one patient had two (*Escherichia coli* and *Klebsiella oxytoca*), and one was colonised by three different species (*E. coli*, *Klebsiella pneumoniae* and *Proteus vulgaris*). Many patients had repeat isolates and several subpopulations were detected during the study period. *E. coli* (n = 8) was the most frequently found species, followed by *K. oxytoca* (n = 4), *Citrobacter* spp. (n = 2), *K. pneumoniae* (n = 2) and *P. vulgaris* (n = 1).

Four of eight patients with *E. coli* had findings of CTX-M genes, belonging to CTX-M group 1 or 9. Multi drug resistance was seen among two of these CTX-M producing isolates. One of two *K. pneumoniae* had a CTX-M enzyme belonging to group 1.

K. oxytoca and *Citrobacter* spp. were found to harbour the chromosomally encoded β-lactamases K1 and Sed1, respectively. In *P. vulgaris* no CTX-M or K1 enzyme was detected.

Conclusions: The prevalence of faecal carriage of isolates with ESBL-phenotype among patients with severe abdominal infections was 10.9%. At admission to hospital 5.4% and 0.8% of the patients had ESBL-producing *E. coli* and *K. pneumoniae*, respectively, in their faecal flora. These data may have implications for antibiotic treatment in abdominal infections.

P631 Presence of extended-spectrum β-lactamase-producing Enterobacteriaceae in the faecal flora of patients from general practice

C. Meex, P. Melin, J.D. Docquier, T. Kabasele, P. Huynen, P.M. Tulkens, D. Giet, P. De Mol (Liège, Brussels, BE)

Objectives: The aim of this study was to determine the extended-spectrum β-lactamase-producing Enterobacteriaceae (ESBL-E) carriage in community patients' faecal flora and to characterise the detected ESBLs.

Methods: This study was performed at the University Hospital of Liège (Belgium). From March 2007 to June 2007, a total of 284 faecal specimens were collected from 284 patients who consulted their general practitioner. Each sample was homogenised in 1 ml of sterile saline and aliquots were inoculated on three different selective culture media: ChromID ESBL agar (bioMérieux) and MacConkey agar + ceftazidime (2 mg/L) and Drigalski agar + cefotaxime (1.5 mg/L). All the Enterobacteriaceae growing on these media were identified and tested for susceptibility by the VITEK 2 (bioMerieux). The detection of ESBL production was performed by combined double disks (ceftazidime, cefotaxime and cefepime disks alone and a disk containing clavulanic acid). Characterisation of these ESBLs was performed by PCR assays targetting blaTEM, blaSHV, blaCTX-M, the most frequent ESBL genes, followed by amplicon sequencing.

Results: Overall, 53 Enterobacteriaceae were recovered on the selective media from 284 samples (18.7%). Among these, 25 were identified as ESBL producers: 20 *Escherichia coli*, 3 *Proteus mirabilis*, 1 *Serratia fonticola* and 1 *Enterobacter aerogenes*. These 25 ESBLE originated from 20 patients (7.04%). Among the ESBL-*E. coli*, the following ESBLs were found: TEM 19 (n = 1), TEM 52 (n = 4), CTX-M 1 (n = 5) and CTX-M 15/28 (n = 2); 2 amplicons of TEM genes were not correctly sequenced. The ESBL from the *E. aerogenes* was TEM 52 and those from the 3 *P. mirabilis* were TEM 24. For 6 isolates, 5 *E. coli* and 1 *S. fonticola*, PCR did not demonstrate any ESBL gene of type TEM, SHV or CTX-M.

Conclusions: (1) Out of all screened community patients, 7% were found to be colonised in their faecal flora with ESBL-E strains. (2) *E. coli* accounted for the majority of ESBL-E isolates, while *P. mirabilis* and *E. aerogenes* were in a minor proportion. No ESBL-*Klebsiella* sp. was recovered. (3) Various ESBL genes were identified. (4) TEM- and CTX-M-derived enzymes were the most frequently encountered

ESBLs. No SHV-derived enzyme was found. (5) The study shows that antimicrobial resistance among Enterobacteriaceae in the community becomes a reality which should probably be taken into account in treatment recommendations.

P632 High prevalence and diversity of extended-spectrum β-lactamases in faecal *Escherichia coli* isolates of healthy humans

L. Vinué, S. Martínez, J.P. del Pozo, Y. Sáenz, C. Torres, M. Zarazaga (Logroño, ES)

Objectives: To study the prevalence and genetic characterisation of extended-spectrum beta lactamases (ESBLs) in faecal *Escherichia coli* isolates of healthy humans and to analyse the surrounding regions of ESBL genes and its possible inclusion in integrons.
Methods: 105 faecal samples recovered from healthy humans were seeded on Levine agar plates supplemented with cefotaxime (2 mg/L) and were incubated at 37ºC for 24 h. One colony per sample with *E. coli* morphology were identified and screened for ESBL production by double-disk test. All ESBL-positive *E. coli* isolates were included in this study. Susceptibility testing to 17 antimicrobials was performed by disk-diffusion test and genes encoding CTX-M, SHV and TEM type β-lactamases were analysed by specific PCRs and sequencing. The genetic environment of blaCTX-M genes as well as the presence of integrons and their gene cassette compositions were characterised by PCR and sequencing. The phylogenetic group of ESBL-positive isolates was determined by PCR.
Results: ESBL-producing *E. coli* isolates were detected in 7 of 105 analysed samples (6.6%). The ESBL genes found were the following ones (number of isolates): blaCTX-M-14a (1), blaCTX-M-14b (1), blaCTX-M-1 (2), blaCTX-M-32 (1), blaCTX-M-8 (1), and blaTEM-52 (1). The genetic environment of blaCTX-M genes were as follows: i) ISEcp1 and IS903 surrounding blaCTX-M-14a gene; ii) IS26/ISEcp1 and orf477 surrounding blaCTX-M-1 gene; iii) ISEcp1 and orf477 surrounding blaCTX-M-32 gene; iv) blaCTX-M-14b included into the integron In60 with dfrA16 plus aadA2 gene cassette arrangement in their variable region; v) the surrounding region of blaCTX-M-8 gene could not be identified. The blaCTX-M-32-positive isolate harboured a class 1 integron which included a variable region of 2000 bp. The phylogenetic groups A, B1 and B2/D were detected in 2, 1 and 4 of our ESBL-positive isolates, respectively.
Conclusions: A high prevalence and diversity of ESBLs are detected in faecal samples of healthy humans, mainly of the CTX-M class. The gene blaCTX-M-14 has been found in structures related with insertion sequences or integrons.

P633 Characteristics of clinical extended-spectrum β-lactamase-producing isolates from companion animals in Finland

S.D. Nyberg, K. Thomson, A. Myllyniemi, K. Pelkola, J. Jalava, M. Rantala (Turku, Helsinki, FI)

Objective: Characterisation of ESBL-producing isolates of animal origin in Finland.
Methods: During a 4-year period 2004–2007, clinical isolates from animals yielded 16 *Escherichia coli*, seven *Enterobacter* sp., two *Acinetobacter* sp., one *Aeromonas* sp. and one *Klebsiella pneumoniae* non-susceptible to cefuroxime or cefotaxime. Bacterial identification was done with conventional biochemical methods and susceptibility testing with microdilution or disk diffusion method. Detection of TEM, SHV, CTX-M, and OXA genes, was performed by PCR and pyrosequencing. Pulsed Field Gel Electrophoresis (PFGE) was used for studying the clonal relationship of the isolates.
Results: Isolates were derived from twelve dogs, nine horses and five cats. For one isolate the animal species was not mentioned. Seventeen isolates were from urine, seven from wound discharge, two from vaginal discharge and one from faeces. Nine isolates carried an ESBL-gene. A CTX-M-1 gene was present in five isolates (4 *E. coli*, 1 *Aeromonas* spp.), while one isolate carried a CTX-M-9 gene (*E. coli*). Two isolates had an SHV-type gene (1 *K. pneumoniae*, 1 *Enterobacter* sp.), and one *Acinetobacter* sp an OXA-51 gene. The PFGE-profile was identical for two ESBL *E. coli* isolates from two different animals, although no regional or temporal relationship was apparent. ESBL genes were not detected in 18 isolates, but non-susceptibilty to 3rd generation cephalosporins suggests the presence of other mechanisms. Some of these isolates were resistant to cefoxitin which may indicate presence of AmpC.
Conclusion: Since isolates resistant to 3rd generation cephalosporins have emerged in companion animals, clinical laboratories should routinely screen bacterial isolates for resistance to these agents. Broad spectrum cephalosporins should be used judiciously in veterinary medicine.

P634 Prevailing occurrence of SHV-12-producing *E. coli* isolates in retail raw meat samples in southern Spain

P. Egea, L. López-Cerero, J. Rodríguez-Baño, M.D. Navarro, Y. Doi, A. O'Keefe, D.L. Paterson, A. Pascual (Seville, ES; Pittsburgh, US)

Introduction: Potential transfer of antimicrobial resistance from enteric zoonotic bacteria of food animals to humans is a cause of concern. Monitoring resistance is essential especially for important human therapeutic antibiotics as narrow spectrum cephalosporins. Currently, sick and healthy food animals are increasingly recognised as reservoir of extended spectrum β-lactamases-(ESBLs)-producing *E. coli*. Previous reports have focused on faecal samples from farm animals and abattoirs, but few data are available from commercial food supply.
Objective: a study was conducted to examine ESBL-producing *E. coli* (ESBLEC) in raw meat samples from Seville and to characterise their antibiotic resistance.
Material and Methods: A total of 94 prepackaged raw meat samples, including chicken, turkey, beef and pork, were purchased from retail stores (large chain, wholesale and deli grocery) in Seville from September through December 2006. After an overnight incubation in broth medium, homogenised were subcultured on McConkey agar supplemented with 1 mg/l cefotaxime or 1 mg/l ceftazidime. Lactose-positive colonies were identified by standard biochemical tests. Screening of ESBL production was done using the double disk diffusion method. ESBL characterisation was carried out by PCR assays with group-specific primers and sequencing. Strain relationship was studied by REP-PCR.
Results: Twenty five samples (27%) yielded 51 unrelated ESBLEC strains. ESBLEC was detected in chicken (13/15, 87%), turkey (7/12, 58%) and beef (1/12, 8%) and pork (4/55) (Chi^2, $p<0.001$). Twelve (37%) samples from the deli grocery were positives, 9 (26%) from the large chain and 4 (14%) from the wholesale store (Chi^2, $p=0.127$). Forty three (84%) strains produced SHV-12 and they came mainly from poultry (93%).
Conclusions: In our study a very high ESBLEC contamination was exhibited in raw poultry for human consumption. In contrast with previous studies, where CTX-M both M-1 and M-9 groups were the main enzymes associated with animals and food samples, the ESBL type predominantly detected in our area was SHV-12.

P635 Multidrug-resistant *Salmonella enterica* serovar Virchow encoding blaCTX-M3 located on an IncN plasmid isolated from Turkish food of avian origin

M.D. Avsaroglu, E. Junker, A. Schroeter, R. Helmuth, M. Akcelik, F. Bozoglu, B. Guerra (Ankara, TR; Berlin, DE)

Objectives: Characterisation of plasmid mediated extended spectrum cephalosporins resistance by a blaCTX-M3 in S. Virchow isolated from Turkish Food of avian origin.
Methods: 76 chicken meat samples were collected from different markets in Ankara, Turkey (2005–2006). All isolates were tested for their susceptibility to 17 antimicrobial agents, and ampicillin resistant

isolates were tested for an extra panel of 11 β-lactams. One S. Virchow PT26 (DMC19) isolate showed a resistance phenotype typical for ESBLs. The presence of blaCTX-M3 was detected by PCR/sequencing. The complete resistance repertoire (resistance genes, class 1 integron and mutations in the quinolone resistance determining regions) of this strain was characterised by molecular methods. The strain was typed by XbaI-PFGE and plasmid profile analysis. Location of ESBLs was determined by hybridisation assay. The plasmid was analysed by RFLP. The incompatibility group of the plasmid was investigated according to replicon typing by PCR. Conjugative properties were examined by bacterial matings.
Results: The S. Virchow isolate had a multi-drug resistance pattern of [AMP–EFT–CTX-CRO-CPD-ATM]–STR–SUL–TMP–SXT-NAL. Together with blaCTX-M3, the strain also carried blaTEM-1-strA/B-sul2-dfrA14 genes. A gyrATyr-87 mutation was responsible for the NAL resistance. No qnrA, B or S genes were detected. The strain did not possess any class 1 integron. The strain showed a common PFGE pattern like other S. Virchow isolates. It had only one plasmid of about 45 kb, named pBD2006. The blaCTX-M3 gene was located on this plasmid. After several intents the pBD2006 could not be transferred by conjugation. The plasmid belongs to the IncN incompatibility group.
Conclusions: blaCTX-M3 genes located in very big plasmids (300 kb) are wide spread among humans isolates in Mediterranean Regions. In the present study, the gene, located on a smaller plasmid, could be associated to food products of avian origin.

Molecular bacterial epidemiology

P636 Molecular identification and clonal dissemination of *Haemophilus haemolyticus* in acute pharyngotonsillitis

N. Yamanaka, M. Hotomi, D. Billal, J. Shimada, K. Yamauchi, K. Fujihara (Wakayama, JP)

Objectives: Bacterial infection plays an important role in the course and pathogenesis of acute pharyngotonsillitis. Although nontypeable *Haemophilus influenzae* (*H. influenzae*) is a human respiratory pathogen, *Haemophilus haemolyticus* (*H. haemolyticus*), the closest relative of *H. influenzae*, is considered to be a pharyngeal commensal. This study was designed to identify *H. haemolyticus* separate from *H. influenzae* by polymerase chain reaction (PCR). Clonal diversity of this pathogen was also evaluated by pulsed field gel electrophoresis (PFGE) in this study.
Materials and Methods: Clinical isolates from acute pharyngotonsillitis were studied to distinguish *H. influenzae* (38 strains) from *H. haemolyticus* (28 strains). *H. influenzae* and non-haemolytic *H. haemolyticus* were originally defined by typical colony morphology on chocolate agar, X and V growth factor dependency, and no reaction in the porphyrin test. Hemolysis was assessed as zones of beta-hemolysis surrounding individual colonies grown on horse blood agar to differentiate hemolytic *H. haemolyticus*. PCR primers were designed to amplify 16S rDNA, 7F3 epitope of outer membrane protein P6 and IgA protease gene (iga) to distinguish *H. haemolyticus* from *H. influenzae*. Clonal diversity of H. hemolyticus was also evaluated by PFGE.
Results: *H. haemolyticus* was distinguished from *H. influenzae* by three independent PCR sets. All strains of *H. influenzae* expressed the 7F3 epitope but lacked the 7F3 epitope in *H. haemolyticus*. The iga gene was also identified in only *H. influenzae*. PCR for 16S rDNA also could distinguish *H. influenzae* from *H. haemolyticus*. There was no clone identified in H. hemolyticus while nontypeable *H. influenzae* showed three clones.
Conclusion: *H. haemolyticus* is considered to be a pharyngeal commensal. It is important to distinguish the microorganism from causative pathogens. However, the standard methods can not reliably distinguish *H. haemolyticus* from *H. influenzae*. The recognition that some strains of apparent *H. influenzae* are *H. haemolyticus* is essential to understand association of true *H. influenzae* with respiratory tract infections.

P637 CagA variants in Iranian *Helicobacter pylori* isolates recovered from patients with different gastroduodenal diseases

M. Douraghi, Z. Karimi, M. Bababeik, M. Esmaeili, M.A. Mohagheghi, M. Eshagh Hosseini, M. Mohammadi (Tehran, IR)

Objectives: The biological activity of CagA protein is related to the variable region of CagA containing variable numbers of EPIYA motifs. Binding of phosphorylated CagA to SHP-2 occurs with varying affinity. CagA is subdivided to the East Asian and Western subtypes based on its binding to SHP-2. The East Asian-type CagA binds to SHP-2 more strongly than the Western-type CagA. Due to the high prevalence of cagA-positive *Helicobacter pylori* (Hp) strains in East-Asian countries as demonstrated in our country, assessment of the presence or absence of cagA alone is not very informative. Consequently, CagA variants typing in term of the subtype and number of EPIYA motifs may be important in determination of the binding affinity of CagA to SHP-2 and the clinical relevance of cagA. The aim of this study was to characterise the CagA variants of Iranian Hp strains.
Methods: Genomic DNA was isolated from 142 Hp strain isolated from infected patients, followed by PCR amplification of the variable region of the cagA gene using cag2 and cag4 primers. Purified PCR products were sequenced. The sequence of each resulting subtype was deposited in the GenBank.
Results: One hundred and twenty four (87.3%) of examined isolates were cagA positive. Six CagA variants differing in length of PCR products were identified. Two to six EPIYA motifs were detected among the sequenced strains. The most prevalent (59.7%) PCR amplicon was 550bp designated as A-B-C type. All of the sequenced CagA variable region were identified as the "Western" type. Although there was no statistical association between any of the CagA subtypes and gastroduodenal disease, a specific CagA subtype yielded longer PCR product (750 bp), designated as A-B-B-B-C-C and was found exclusively in GC patients.
Conclusion: Evaluation of the variations in the cagA variable region seems as an effective method of screening for highly virulent cagA-positive strains. The primary finding of our study showed that Iranian stains have a lower binding affinity to SHP-2 than other East Asian strains. It is not unlikely that circulating of A-B-C type as the most prevalent type in Iranian dyspeptic patients and lower binding affinity of our strains to SHP-2 result in lower frequency of gastric cancer and peptic ulcer diseases in our population compared to other East Asian countries.

P638 cagA/vacA genotyping of *Helicobacter pylori* strains isolated from Cuban and Venezuelan patients

V. Guariglia, D. Ortiz, M. Cavazza, M. Correnti, M. Avila, B. Gutiererz, M. Perrone, F. Megraud (Caracas, VE; Habana, CU; Bordeaux, FR)

Among the different genetic determinants involved in *H. pylori* virulence we find the citotoxin associated gene (cagA) and the vacuolating citotoxin gene (vacA). Different studies have shown the importance of the presence of these genes in the strain affecting a patient and the development of a gastric disease.
Objective: The aim of the study was to determine the presence of different *H. pylori* cagA/vacA genotypes among patients with gastritis in Cuba and Venezuela.
Methods: Biopsies were taken from 61 patients from Venezuela and from 71 patients from Cuba. Biopsies were cultured on selective media. DNA from the biopsies was obtained using a proteinase K protocol. A region of 349 pb of the cagA gene was amplified by PCR using the primers F1/B1, VA1-F/VA1-R set of primers to amplify the 259 bp (s1) or the 286 bp (s2) regions of the conserved portion of the vacA gene and VAG-R/VAG-F set of primers to amplify the 567bp (m1) or the 642bp (m2) regions of the conserved portion of the vacA gene. All the amplified regions were resolved on a 1% agarose gel electrophoresis at 80 volts for approximately 2 hours.

Results: The 349pb region of the cagA gene was amplified in 34 of the 61 Venezuelan patients (56%) and in 20 of the 71 Cuban patients (28%). We found a significant difference (p = 0.0015) between the presence of the cagA gene in both countries. When we analysed the prevalence of cagA related to the allelic variants we found a significant difference between both countries: in Venezuela we observed a significant higher percentage of the genotype cagA positive/m1s1, in comparison with Cuba (p = 0.0025). The percentage of cagA negative/m1s1 strains in Cuba was significantly higher than in Venezuela (p = 0.04). Out of the 71 patients from Cuba we found that in 8 of them there was co infection with a least two different strains since we detected both m1 and m2 alleles on them.

Conclusion: We found significant differences between the genotypes of the strains from both countries. Since the cagA and vacA genes are some of the virulence factors of *H. pylori* related to its pathogenesis and the severity of the gastric disease, these results are of great importance to the regional health systems of each country for the control, tracking and prevention of gastric cancer.

Grants: FONACIT G-2005000371 / LOCTI-IBA-02–2007 and IBA-03–2007. Inalum-Alumnware

P639 Qualitative and quantitative composition of gut microbiota from cystic fibrosis patients

J.M. Sánchez-Calvo, M. Garcia-Castillo, A. Lamas, M. Rodriguez-Baños, F. Baquero, L. Suárez, R. Cantón, R. del Campo (Madrid, ES)

Objective: To analysed the gut microbiota of cystic fibrosis (CF) patients by classical culture-based methods and also by non-culture molecular approaches.

Methods: Faecal samples from 18 CF-patients and also from 20 healthy volunteers (HV) were seeded in selective agar plates including: M-*Enterococcus*, manitol-salt, MacConkey, MRS, and ESBL. An additional blood-Columbia agar plate was including in order to estimate the aerobic bacterial concentration in faeces, and also the organims not recovered on selective plates. Five different colonies per morphology was subculture in the corresponding plates, and their clonal relationship was assessed by PFGE. Antimicrobial susceptibility was tested in the different PFGE pattern clones by agar dilution method. Total DNA was obtained from the faeces (QuiAmp minikit, Quiagen) and quantitative-PCR experiments were conducted in order to know the bacterial density for the *Bacteroides–Prevotella–Porphyromonas*, *Fusobacterium*, and Lactic Acid Bacteria (LAB) groups. PCR-DGGE was performed with universal primers sets (V2-V3 region of 16S) and also with the described bacterial groups.

Results: Considering the blood-Columbia agar plate, lower bacterial charge was found in the CF faecal samples than in the HV. Curiously, Gram-negative bacteria were not detected in CF samples, neither in the selective mediums (MacConkey and ESBL) nor in the blood-Columbia agar. Enterococcal and staphylococcal clones were detected only in 10 and 9 CF patients, respectively, whereas for HV these genera were represented in all subjects. Several LAB genera as *Lactococcus*, *Lactobacillus*, and Pediococcus were detected in almost 50% of the CF samples. Multirresistance to four or more antibiotic families were corroborated in all CF isolates. Quantitative-PCR results showed statistical differences among the density proportions of the bacterial groups in the CF-patients versus the HV: *Bacteroides–Prevotella–Porphyromonas* (6:1), *Fusobacterium* (1.8:1), and LAB (2:1) groups. DGGE-experiments showed particular bands associated only to CF-patients.

Conclusion: Qualitative and Quantitative significant differences were detected in the CF gut microbiota when comparing with that of HV, being relevant the higher amounts of anaerobes in the CF faces and the absence of Gram-negative cultivable organism. These differences can be related with antimicrobial selective pressure and particular gut mucosal conditions in CF patients.

P640 Serotype distributions and molecular characteristics of *Vibrio parahaemolyticus* isolates in Malaysia

F. Shamsuddin, V. Nadarajah, N. Ahmad, R. Md Yasin, M. Nishibuchi, M. Ishibashi, K.H. Ong (Kuala Lumpur, MY; Kyoto, JP)

Objectives: To determine the serotype distributions of *Vibrio parahaemolyticus* isolates in Malaysian clinical isolates and to identify the genotypic characteristics of the strains.

Methods: A collection of fourteen *V. parahaemolyticus* clinical isolates from various hospitals and National Public Health Laboratory in Malaysia from year 1997 to 2000 and 2005 to 2007 were serotyped using commercial O and K antisera. The isolates were subjected to PCR analysis to detect species-specific toxR gene of *V. parahaemolyticus*, tdh and trh toxin genes, presence of orf8 gene and confirmation of pandemic strain by group-specific PCR (GS-PCR).

Results: From the fourteen clinical isolates, eight were serotyped as O3:K6 making it the dominant serotype (57.14%), followed by O4:K68 representing three isolates (21.43%) and one strain each representing serotype O1:KUT, O3:K5 and O4:K8 respectively. All of these isolates were positive for the toxR gene and were confirmed as *V. parahaemolyticus*. All the isolates were also positive for the tdh toxin gene except for one strain of serotype O1:KUT. None of the isolates were positive for the trh gene. Only those of serotype O3:K6 and O4:K68 possessed all genotypic characteristics of the pandemic strain, being positive for the tdh gene and negative for trh gene, positive for the orf8 structural gene and were also GS-PCR positive. However, the three other serotypes were negative for orf8 gene and were GS-PCR negative.

Conclusion: This study showed that pandemic serotypes are present in Malaysia and are represented by serotype O3:K6 and O4:K68. In this limited number of isolates, O3:K6 and O4:K68 were shown to be the dominant serotypes. These particular strains possessed all structural genes of the pandemic strain which were further confirmed by GS-PCR method.

P641 Faecal prevalence and strain diversity of *Listeria monocytogenes* in healthy cattle, sheep and swine herds in northern Spain

J. Esteban, B. Oporto, G. Aduriz, R. Juste, A. Hurtado (Derio, ES)

Objectives: Although the incidence of human listeriosis is low compared to salmonellosis or campylobacteriosis (0.88 cases per 100,000 inhabitants per annum in the last 5 years in the Basque Country), *Listeria monocytogenes* is among the most important foodborne bacterial pathogens due to the high mortality rate (20–30%) and severity of the disease. *L. monocytogenes* is a ubiquitous organism that inhabits the intestinal tract of various livestock species that act as major reservoirs and source of human infection via faecal contamination of food products. The aim of this study was to determine the prevalence and strain diversity of *L. monocytogenes* in healthy ruminants and swine farms.

Methods: Faecal samples from 30 animals per farm were collected from 343 farms (120 ovine, 124 beef cattle, 82 dairy cattle and 17 porcine) and screened in pools by an automated enzyme-linked fluorescent immunoassay (VIDAS® LMO2, bioMérieux). Positive samples were subcultured onto the selective and differential agar ALOA and biochemically confirmed. Within-herd prevalence of *L. monocytogenes* was investigated by individually analysing 50 animals from a selection of pool-positive herds. Isolates were characterised by serotyping and ApaI PFGE analysis.

Results: *L. monocytogenes* was isolated from 46.3% of dairy cattle, 30.6% beef cattle and 14.2% ovine farms, but not from swine. Within-herd prevalences established by individual testing of 197 sheep (4 herds) and 221 cattle (5 herds was 1.5% (0.0–4.1%) and 21.3% (5.1–72.3%), respectively. Serotyping of 114 isolates (20 ovine and 94 bovine) identified complex 4b the most prevalent (81.7%), followed by 1/2a (14.0%), 1/2b (2.1%) and 4c and 4e (1.1% each). Distribution of serotypes varied slightly among the different host species. PFGE analysis performed on 67 isolates indicated that the *L. monocytogenes* population

in Basque farms is genetically highly diverse and identified the presence of different strains within each farm.

Conclusion: Prevalence values observed in ruminants indicate that good management practices and control strategies at the production level are crucial to reduce *L. monocytogenes* contamination in the live animal at the primary production level before entry to the slaughterhouse to reduce risk of human infection.

P642 Phylogenetic grouping of *Escherichia coli* isolates from patients' stool samples with diarrhoea

M. Trkov, D. Dovecar, M. Paragi, M. Grabnar, J. Ambrožic Avguštin (Ljubljana, SI)

Objectives: *Escherichia coli* is a normal inhabitant of the gut flora but is also frequently isolated in cases of infections. The population structure of extraintestinal strains has been studied during the last decade through the assignment of *E. coli* isolates to one of the four main phylogenetics groups (A, B1, B2 and D). Since less data are available for *E. coli* causing intestinal infections, the aim of our study was to assess the implication of the genetic background of selected intestinal *E. coli* isolates.

Methods: 66 *E. coli* isolates from patients' stool samples with diarrhoea of unknown origin, were assigned to one of the phylogenetic groups using the method described by Clermont et al..Virulence genes vtx1, vtx2, eae, ipaH, eltA, and estA were detected by PCR using the "DEC Primer Mix" produced by Statens Serum Institut, Denmark. EHEC-hlyA was determined on enterohemolysin agar plates, Oxoid, England and by PCR using primer pair hlyen1/hlyen2 (5′-GGT GCA GCA GAA AAA GTT GTA G-3′/5′-TCT CGC CTG ATA GTG TTT GGT A-3′). The O antigens were determined by using antisera produced by the Institute of Immunology, Croatia and Sifin, Germany.

Results: 10, 17, 25 and 14 isolates were placed into the phylogenetic groups A, B1, B2 and D, respectively. Serological groups found within group A isolates were O5, O6, O15, O75 and O86. Only one of the two O157 isolates within this group carried an eae gene. In none of the other nine isolates vtx1, vtx2, eae, ipaH, eltA, or estA genes were detected. To our surprise all of the 12 determined O26 isolates were placed into group B1. All 12 isolates carried an eae gene, nine were EHEC-hlyA positive and two carried additional the vtx1 or vtx2 gene. The most prevalent O serological groups found within B2 phylogenetic group were O1, O2, O4, O6, O18 and O142. One of the isolates was O157 with a detected eae gene. 14 isolates were placed into group D. In all of the six determined O157 isolates the eae gene was detected. Additionally the O157 isolates carried either the EHEC-hlyA and/or the vtx2 gene. The eae and EHEC-hlyA genes were also found in the two O145 isolates from phylogenetic group D.

Conclusions: The majority of the O26 and O157 isolates associated either with eae, vtx1, vtx2, or EHEC-hlyA genes were placed into the B1 or D phylogenetic group. Thus, phylogenetic grouping could be partially used in screening projects for a rapid assessment of potentially pathogenic *E. coli* strains (EPEC and VTEC associated) in Slovenia.

P643 Ciprofloxacin resistance, virulence determinants and phylogenetic background of uropathogenic *Escherichia coli* isolates from general practice patients in Slovenia

J. Ambrožiè Avguštin, A. Palandacic, M. Trkov, M. Grabnar (Ljubljana, SI)

Objectives: Urinary tract infections are mainly caused by uropathogenic strains of *Escherichia coli*. Knowledge on virulence traits and phylogenetic background of extraintestinal (ExPEC) *E. coli* has increased tremendously over the last years. Results of several studies revealed, that human ExPEC strains mostly belong to phylogenetic group B2 followed by group D, and that quinolone-resistant ExPEC strains have less virulence factors (VFs) than quinolone susceptible strains. The aim of our study was to gain insight into the genetic difference between ciprofloxacin susceptible and resistant strains recovered from urinary tract infections of a random population of patients subjected to empirical antimicrobial treatment in general pratices in the Ljubljana region.

Methods: *E. coli* isolates recovered from patients with symptoms of urinary tract infections were collected and identified at the Institute of Public Health of the Republic of Slovenia. A random sample of 44 ciprofloxacin resistant and 53 ciprofloxacin susceptible isolates, as determined by the disk diffusion method according to the CLSI standards, were included in the study. All isolates were placed into phylogenetic group A, B1, B2 or D as described by Clermont et al.. The isolates were screened by PCR for 23 virulence genes, including adhesins, serum resistance genes, toxins, invasins, and genes involved in iron aquisition.

Results: Alltogether, 16.5%, 5.1%, 45.4% and 33% of the isolates were placed into phylogenetic group A, B1, B2 and D, respectively. Among the ciprofloxacin susceptible isolates the most prevalent group was B2 (56.6%), followed by group D (30.3%), whereas the resistant isolates were almost equally distributed within groups D, B2 and A (36.2%, 32% and 27.3%). Virulence genes were found in both resistance groups. However, there was an obvious difference in the distribution of kpsMTII, usp and iroN genes, being detected in 71.7%, 30%, 67.9%, and in 43.1%, 13.6% 38.6% of the ciprofloxacin susceptible and resistant isolates, respectively. The prevalence of virulence genes varied significantly between isolates from different phylogentic groups and also within each group if the isolates were divided into subgroups according to the ciprofloxacin resistance profile.

Conclusions: Since non-B2 ciprofloxacin resistant *E. coli* isolates with less VFs, are frequently isolated from general practice patients, they have to be considered as important uropathogens.

P644 M serotyping of group A beta haemolytic streptococci isolated from throat infection by emm-gene sequence analysis from Turkey

G. Akca, N. Sultan, D. Engin, M. Yalinay Cirak, R. Olguntürk (Ankara, TR)

Objective: Following group A beta haemolytic streptoccoci related throat infections, invasive diseases may occur due to several virulence factors such as M protein. The purpose of this study is to determine emm types of Turkish people suffering throat infections and investigate the relation between M-types, sex, age and type of diseases.

Methods: 114 *S. pyogenes* strains were isolated from throat cultures and identified with conventional microbiological methods (culture, serotyping, API Strep®). emm specific PCR products of these strains were obtained using emmP1, emmP2 primers recommended by Centers of Disease Control. emm types of the strains were sequenced by DNA cycle-sequencing analyse. Local and global alignments were performed by Clustal W v1.7 software and Blast server. Phylogenetic dendrogram was drawn. The correlation between "emm" types and sex of the patients have been evaluated by Chi-square test statistically. The distribution of age and "emm" types of the patients were analysed by Mann-Whitney U test.

Results: Of the 114 strains (85%), 97 strains' emm types were identified as 1, 3, 4, 6, 9, 11, 12, 14, 18, 22, 24, 29, 33, 43, 48, 75, 77, 78, 89, 90, 102, 112, 118. The other 17 types could not have been identified and accepted as nontypeable. The most frequently seen types were emm 12, 3, 1, 75, 29 respectively which were isolated from school age children under 10-years-old. The patients' age distribution was found variable but mostly accordant to emm types which were identified from invasive streptococcal infections. It was found that there's no statistically significant difference between the emm types and the sex of the patients. Besides, 15 of emm/M types which were determined in this study, including the most frequently seen types (emm 1, 3 and 12) were found that they were also in the contents of M types of 26 VV vaccine (suggested to be effective as 76.9%) developed for Group A streptococci (GAS)

Conclusion: This preliminary study is the first emm-gene sequence analysis presented from Turkey which determines the M types of GAS strains in our country. If the research can be generalised to all different regions we will get more exactly and comprehensive results about the M types of Turkish people.

P645 Molecular epidemiology and pathogenesis of pneumococcal cerebral abscesses in Scotland

D.J. Inverarity, J. Hinds, M. Diggle, G. Edwards, T.J. Mitchell (Glasgow, London, UK)

Objectives:
- To document the molecular epidemiology of pneumococcal cerebral abscesses in Scotland.
- To perform microarray DNA comparative genomic hybridisation (CGH) using isolates from the commonest multi locus sequence type (MLST) and serotype to document regions of diversity in their genomes.
- To assess in vitro expression of virulence-associated genes from these isolates.

Methods:
- The Scottish Meningococcal and Pneumococcal Reference Laboratory database of invasive pneumococcal cases was searched for cases of cerebral abscess where pneumococci had been grown from pus.
- DNA was extracted from overnight cultures at 37ºC using a phenol chloroform extraction method. RNA was extracted from cultures in brain heart infusion broth at 37ºC grown to an optical density at 600nm of 0.6 using an RNeasy Mini kit (Qiagen). Fluorochrome Cy^{TM}3 or Cy^{TM}5 dCTP (GE Healthcare) was incorporated into DNA or cDNA as part of a randomly primed polymerisation reaction. Competitive hybridisation against reference DNA or cDNA extracted from TIGR4 (a fully sequenced serotype 4 isolate) was performed on prehybridised glass slide microarrays constructed by robotic spotting of PCR amplicons. Slides were scanned (ScanArray®, Packard Biosciences) and data analysed using Bluefuse (BlueGnome) and Genespring GX 7.3.1 (Agilent Technologies) software.

Results:
- Of 8 identified cases, 5 were male and 5 died from their disease within 30 days of culture (overall case fatality 62%). The serotypes seen (n = 8) were serotype 3 (37%), 4 (24%), 10A (13%), 12F (13%) and 19F (13%). MLST data was available for 6 isolates – ST180 (50%), ST162 (16.7%), ST218 (16.7%), ST246 (16.7%).
- DNA CGH of two serotype 3 ST180 isolates suggested that gene deletions were present in several previously recognised regions of diversity.
- RNA expression microarray analysis identified several up-regulated, virulence associated genes. The functions of relatively few of these genes were known but included an iron ATP transporter – ATP binding protein (SP0242), hyaluronidase (SP0314) and a serine protease (SP2239).

Conclusions:
- Most cases of pneumococcal cerebral abscess in Scotland are not preventable using existing formulations of pneumococcal conjugate vaccine.
- A microarray approach to identify which genes are present and expressed by pneumococci causing this condition can identify virulence associated genes and their products which could be targeted by alternative prevention strategies or novel vaccines.

P646 A case of cutaneous listeriosis in a man

I. Zdovc, K. Zelenik, M. Pate, J. Avbersek, M. Lusicky, B. Krt, M. Ocepek (Ljubljana, Maribor, SI)

Objectives: In humans, listeriosis caused by *Listeria monocytogenes* usually occurs in certain high-risk groups (neonates, pregnant women, immunocompromised adults) but rarely in persons without predisposing factors. Sepsis, meningitis and meningoencephalitis are common features of listeriosis in humans; rare cutaneous form of the disease is linked mainly to occupational hazards (veterinarians, laboratory workers).

A case of *L. monocytogenes* skin infection in a man is presented. A 54-year-old male veterinary practitioner developed pustular changes on the skin of arms and hands after assisting the delivery of stillborn calf. During the parturition one of his gloves tore and he continued with exposed hands. He suspected the bacterial infection to be the cause for stillbirth therefore he took a sample of placenta and sent it to the laboratory for bacteriological examination. Later, pustular changes developed on his skin; the swabs were taken for bacteriology and *L. monocytogenes* was isolated. The patient was treated successfully with amoxicillin and clavulanic acid.

Methods: Cultivation, identification, serotyping and genotyping of the strains from pustulae and placenta were performed. As a genotyping method, pulsed-field gel electrophoresis (PFGE) was used and performed following the CDC standardised PulseNet protocol for *L. monocytogenes* using restriction endonucleases AscI and ApaI. The genotyping results were analysed using BioNumerics software (Applied Maths).

Results: Pure cultures of small haemolytic colonies suspicious of *Listeria* spp. were grown after 24h incubation on sheep blood agar from all specimens. The colonies were identified as *L. monocytogenes* with biochemical kit API *Listeria* (BioMerieux). Serotyping resulted in serotype 4b in all isolates. The cleavage of the DNA with both AscI and ApaI exhibited identical PFGE restriction patterns of all strains suggesting the zoonotic transmission of the infection with *L. monocytogenes*.

Conclusion: To the best of our knowledge, this is the first case of cutaneous listeriosis where the evidence for zoonotic transmission of *L. monocytogenes* was supported by genotyping methods.

P647 Phylogenetic analysis of genus salmonella based on polyphasic and numerical taxonomy

M. Tajbakhsh, K. Motavaze, B. Noori nayer, M. Chiani, M. Zali (Tehran, IR)

Objective: The genus *Salmonella* is a member of the family Enterobacteriaceae. There are over 2500 serotypes of this genus based on antigenic differences associated with gasteroenteritidis and enteric fever (typhoid) in human. The division of *Salmonella* into seven major groups has been confirmed by sequence analysis of house keeping, 16S rRNA and invasion genes.

In this study two method of phylogenetic relationship were used. Sequencing method of 16S rRNA and gyrB used to polyphasic taxonomy and RAPD-PCR were used to numerical taxonomy.

Method: Fourty and thirty six strain which isolated from clinical samples were used to sequence and RAPD-PCR analysis respectively. After serotyping their DNA were extracted by phenol chloroform method and PCR amplification and RAPD-PCR were done by universal, sequencing and random primers.

At last PCR products run on agarose gel 1.2% and staining with Ethidium Bromide.

Sequencing results analysed by Clustal X, DNA Star, BioEdit, MEGA4 and RAPD-PCR results was analysed by NTSYS 2 softwares.

Result: The similarity with 16S rRNA gene sequence99.7%, 23S rRNA 98.4–100%, gyrB 97.2–99.8% and amino acid sequence of gyrB 99.8–100% were obtained.

According to the results, 16S rRNA sequences showed poor separation at or below species level. 23S rRNA gene sequence data was better than 16S rRNA to analyse differentiation at the species, subspecies level. The gyrBgene (topisomerase type II) is useful to analyse closely related species at subspecies and serovar level. It was observed that gyrB separation is better than 23S rRNA sequences.

The results of RAPD-PCR were defferent. Based on the primer similarity patterns were different, but the average of them observed between 70–89%.

Conclusion: RAPD-PCR results showed that this method is useful to analyse similarity between several serotypes of *Salmonella*. It is not suitable to Identify unknown isolates according to the genetic pattern of RAPD-PCR.

In contrast of sequencing method this technique is cheap and easy, but it's resolution and sharpness less than sequencing method.

So sequencing method is the best for characterisation and identification of *Salmonella*'s strains for epidemiology and phylogenetic study. A large

number of groups within Bacteria can define and distinguished from each other by this method.

Carriage of MRSA and MSSA

P648 The carriage population of *Staphylococcus aureus* from Mali is composed of a combination of pandemic clones and the divergent genotype ST 152

R. Ruimy, A. Maiga, L. Arman-lefevre, I. Maiga, A. Diallo, A. Koumare, S. Koumare, K. Wattara, A. Andremont, E.J. Feil (Paris, FR; Bamako, ML; Bath, UK)

Objectives: To characterise a sample of *Staphylococcus aureus* isolates from asymptomatic carriage in Mali, Africa, and to compare the results to the known diversity of the carriage population in order to evaluate the role of microepidemic and pandemic clonal spread in shaping *S. aureus* population structure.

Methods: Nasal swab was performed in 448 patients admitted for emergency surgery to a single hospital point G in Bamako. *S. aureus* isolates were characterised by multilocus sequence typing and the results compared against the entire MLST data set and a previous study of carriage isolates from the UK. We used a combination of eBURST and phylogenetic approaches to analyse the data.

Results: Prevalence of nasal *S. aureus* carriage was 19.6% (n = 88). Carriers differed from non carriers for gender (51% vs 35%) and for mean age (41 vs 51.6) ($p < 0.05$) but not for chronic health status and previous hospitalisation. Only one isolate was meticillin resistant. Of the 87 meticillin susceptible isolate, 97% were resistant to penicillin, 6% to erythromycin and 74% to tetracycline. The 88 isolates characterised by MLST were found to correspond to 20 STs. Eighteen of these STs were present in the MLST database and two STs were new. No new alleles were detected. Seven of the 20 STs (ST5, ST8, ST15, ST30, ST88, ST152, ST291) were found in at least 4 strains, 4 of the STs (ST1, ST101, ST120, ST852) were found in 2 or 3 strains, and 9 of the STs corresponded to only a single isolate. We note the presence of many of the commonly recorded *S. aureus* clonal complexes in the Malian carriage population (CC15 (28%), CC8 (8%), CC5 (7%), CC30 (4.5%), CC88 (4.5%), CC45 (3%), CC121 (2%)) but also a high frequency (~24%) of the previously rare genotype ST 152.

Conclusion: Our results confirm the pandemic spread of many *S. aureus* clonal complexes, an observation which challenges purely neutral hypotheses regarding their origin and maintenance. In contrast, the high prevalence of ST 152 demonstrates that microepidemic transmission may also be important, and that much of the diversity of *S. aureus* population remains to be uncovered.

P649 Frequency, molecular typing and association with clinical disease of *Staphylococcus aureus* Panton-Valentine leucocidin positive isolates in a tertiary hospital

E. Vagiakou, G. Ganteris, S. Vourli, M. Orfanidou, A. Vatopoulos, H. Malamou-Lada (Athens, GR)

Objectives: To evaluate the frequency, the molecular typing and the association with clinical disease of *S. aureus* carrying Panton-Valentine leucocidin (PVL) from hospitalised and outpatients during 22 months (1/2006–11/2007)

Methods: During the study period 405 *S. aureus* strains were isolated from soft tissue abscesses, purulent skin infections and nasal swabs obtained from hospitalised and outpatients. *S. aureus* strains were identified by conventional methods and automated system VITEK 2 (bioMerieux). The antibiotic susceptibility testing was performed by disk diffusion agar method and the determination of MICs by VITEK 2. PVL genes (lukF-PV, lukS-PV) and SCCmec types were determined by PCR, while the genotypes of the isolates were investigated by pulsed field gel electrophoresis (PFGE)

Results: A total of 405 *S. aureus* strains were isolated from different patients (312 from hospitalised and 93 from outpatients). MRSA strains were 228 out of 405 (56.3%). Especially 61.5% (192/312) MRSA strains were recovered from different wards of the hospital and 39.8% (37/93) from outpatients. PVL+ strains represented 9.6% (39/405) of the isolated *S. aureus* strains (38 community acquired (CA) and only one hospital acquired) while PVL+ strains represented 16.7% (38/228) of the isolated MRSA. All of the CA MRSA strains were PVL+ (37/37, 100%) and one MRSA PVL+ strain was isolated from nosocomial infection (1/192, 0.5%). One MSSA PVL+ was isolated from an outpatient. The origin of PVL+ strains was: abscesses (25), nasal carriage (7), furunculosis (3), cerebrospinal fluid (CSF) (1), cellulites (1), pyomyocitis (1), peritoneal catheter (1). All of the MRSA and MSSA PVL+ strains were SCCmec type IV by PCR, while 13 PVL+ strains were also investigated by PFGE and showed only one clone ST80. All the MRSA PVL+ isolates were resistant to oxacillin (OXA), kanamycin (KA), tetracycline (TE) and intermediate susceptible to fucidic acid (FA).

Conclusions:

1. In our hospital the prevalence of *S. aureus* PVL+ strains was approximately 10%, while the prevalence of the MRSA PVL+ strains was approximately 17%
2. All CA MRSA and one CA MSSA strain were PVL+ SCCmec type IV and 13 of them were genotyped as ST80
3. One MRSA PVL+ strain was isolated from CSF of a hospitalised patient with clinical signs of meningitis
4. The MRSA PVL+ strains had the same unique resistance pattern to antibiotics (resistance to KA, OXA, TE and intermediate resistance to FA)

P650 PVL(+) MRSA causing infections in hospitalised patients

A. Wong-Beringer, M. Lee, J. Yamaki, K. Shriner (Los Angeles, Pasadena, US)

Objectives: Concerns for Panton-Valentine leukocidin (PVL) producing community-associated (CA) MRSA strains overtaking healthcare-associated (HA) infections and the potential for severe infections in association with PVL expression level have led us to determine 1) molecular epidemiology, 2) disease spectrum, and 3) correlation of disease severity with PVL gene expression level in hospitalised patients infected with PVL(+) MRSA strains.

Methods: 186 MRSA isolates obtained from patients during 7/05–6/07 were saved for molecular characterisation while medical charts of patients were reviewed for relevant demographic, laboratory, and clinical data. We screened all isolates for the presence of lukS-F gene by PVL Evigene® test (AdvanDx, Woburn, MA: a qualitative nucleic acid hybridisation assay for research use only). Using published protocols, PCR typing for SCCmec types (I-IV), USA300;ST8 and PVL transcripts by reverse transcriptase-PCR using SYBR green with primer specific for lukF gene were performed on a subset of strains. MRSA NRS384 (PVL(+) USA300;ST8, SCCmec IVa) and NRS22 (PVL(–), USA600;ST45, SCCmec II) strains served as positive and negative controls respectively.

Results: PVL(+) strains caused 45% (83/186) of MRSA infections in hospitalised adults; 54% were HA per clinical criteria. 96% of PVL(+) strains (52/54) belong to USA300 and 85% (46/54) carried SCCmec type IV cassette. CA-infections were 92% cellulitis +/– abscess plus 1 necrotising fasciitis. HA-infections were more likely to be invasive (pneumonia, bacteraemia) than CA (53% vs 5%, $p < 0.05$), with 60% from nursing home residents. Patients with HA compared to CA infections were older (mean age: 68 vs 48y, $p < 0.0001$) with higher APACHE II score (12.3 vs 3.4, $p < 0.0001$). Of the PVL(+) isolates tested (n = 61), pvl transcript levels ranged from 0 to 8.9 fold higher than control strain. When grouped based on level of pvl gene expression, strains with 2-fold higher mRNA levels vs 0–2 fold relative to control strain were more frequently CA (57% vs 43%) and less likely to cause invasive infections (43% vs 55%) such as pneumonia (7% vs 32%).

Conclusion: Over half of the USA300, SCCmec IV, PVL(+) strains caused healthcare rather than community-associated MRSA infections in adults, with the predominant place of acquisition in the nursing home.

PVL expression levels vary widely among clinical isolates; high PVL expression levels do not predict invasive disease.

P651 Gastro-intestinal carriage of MRSA in patients with community-acquired diarrhoea

N.K. Cope, J. Smullen, K.G. Kerr, A.M. Snelling (Harrogate, Bradford, UK)

Objectives: There is increasing concern about cases of infection with meticillin resistant *Staphylococcus aureus* (MRSA) in the community, but comparatively little work has been done on reservoirs for MRSA outside the hospital. Since *S. aureus* has the potential to colonise the gut and may be enterotoxigenic, we sought to determine the prevalence of MRSA in diarrhoeal samples originating from the community.
Methods: During a year-long survey, faecal samples from non-hospitalised patients submitted for standard investigation of diarrhoeal symptoms were also screened for *S. aureus* by the diagnostic laboratory. Samples were cultured on mannitol salt agar at 37ºC in aerobic conditions for 48 hours. *S. aureus* isolates were identified by latex agglutination and DNAse activity, and MRSA were confirmed by resistance to cefoxitin.
Results: Of 2624 faecal samples investigated, 405 (15.4%) tested positive for the presence of *S. aureus*. Of these, 384 (14.6% of all samples) yielded meticillin sensitive *S. aureus* (MSSA) and just 21 (0.8%) yielded MRSA. The latter originated from patients aged 3 months to 95 years and 15 (71%) of these had no previous history of colonisation or infection with MRSA. However, the majority, (16/21 or 76%) of the MRSA isolates came from patients aged over 75 years. The overall carriage rate of MRSA in stool samples from non-hospitalised individuals aged over 75 years, with diarrhoea was 11% (16 of 144 specimens). This compares to an MRSA gastrointestinal prevalence of 7.6% amongst elderly patients with nosocomial diarrhoea in our hospital over the same time period.
Conclusion: MRSA colonisation is a risk factor for subsequent infection. This study has demonstrated that the gastrointestinal tract can be a significant reservoir of MRSA in the over 75s living in the community, and it is possible that strains are being disseminated via diarrhoeal episodes. This has consequences for control of MRSA in the community, where emphasis is often placed on controlling just nasal and skin colonisation. Further studies of faecal MRSA are warranted, including their enterotoxin status and risk factors for gastrointestinal colonisation.

P652 Prevalence of and risk factors for colonisation with meticillin-resistant *Staphylococcus aureus* at the time of hospital admission

A. Antoniadou, F. Pliarchopoulou, D. Plachouras, E. Karaiskos, S. Atmatzidou, K. Protopapas, S. Tsikrika, K. Kouvelas, E. Moschona, S. Athanasia, A. Zafiraki, E. Papadomichelakis, H. Giamarellou (Athens, GR)

Objective: To determine the prevalence of MRSA colonisation among patients presenting for hospital admission, its correlation with community-acquired MRSA (CA-MRSA) prevalence and to identify risk factors for MRSA colonisation
Methods: In a tertiary teaching hospital, surveillance cultures from the nares, axilla and inguinal areas were performed at the time of admission for all patients except those admitted in the oncology and hematology unit. Demographic information and possible risk factors for colonisation were also recorded.
Results: Swab samples were collected from 937 patients presenting for admission in a year. Patients lived in urban areas in 87%, had a mean age of 57years (median 63) and a female to male ratio of 1.1:1. *Staphylococcus aureus* was isolated from 142 (15.1%) patients and MRSA from 30 (3.2%) of the patients (20% of colonising isolates). Detection of colonisation was 88.7% in the nares, 40.8% in the axilla and 51.4% in the inguinal area. In 3 (2.7.%) and 7 (4.9%) colonisation was only evident in the axilla and inguinal area respectively.
All colonising MRSA isolates exhibited in their sensitivity tests the pattern expected for CA-MRSA with the majority of them sensitive to cotrimoxazole, clindamycin, minocycline, rifampin and quinolones. Interestingly tetracycline and fucidic acid were inactive in the majority of strains. In the multivariate analysis comparing MRSA-colonised to MSSA-colonised patients, independent predictors of MRSA colonisation were: age <50 ($p=0.017$), the presence of an indwelling urinary catheter ($p=0.036$), the absence of hospitalisation the preceding year ($p=0.02$) and the presence of skin disease ($p=0.009$).
Conclusion: Colonisation with MRSA of patients admitted to the hospital is low and probably reflects the prevalence of colonisation with CA-MRSA in the community. Risk factors for MRSA acquisition do not correlate with previous contact with healthcare facilities but with younger age, skin diseases (affecting skin integrity) and debilitating conditions (as expressed by the presence of an indwelling urinary catheter). Larger sample of data may be required to further explore risk factors associated with MRSA colonisation in the community.

P653 Identification of the transmission vectors of *Staphylococcus aureus* circulating in a neonatal intensive care unit

T. Conceicao, M. Aires de Sousa, R. Barroso, E. Paulino, L. Sancho, M. Brito, J. Garrote, H. Carreiro, M. Machado, H. de Lencastre (Oeiras, Lisbon, PT; New York, US)

Objectives: The neonatal intensive care unit (NICU) of Hospital Fernando Fonseca, Lisbon, Portugal assists an average of 450 newborns/year and employs 100 healthcare workers (HCW).
Previous reports revealed that in 2002, 22% of the infections at the NICU were due to staphylococci. Identification of the reservoirs and routes of transmission of these microorganisms is a matter of major concern.
Methods: Between July 2005 and June 2007, 10 infection episodes occurred at the NICU. *Staphylococcus aureus* isolates were recovered during each episode from the infected babies, from nasal swabs of parents and HCW that had contact with the babies, and from the environment. The isolates were characterised by PFGE, spa typing and multilocus sequence typing. Virulence determinants were detected by multiplex PCR.
Results: All but one of the 10 infection episodes (chronologically designated I to X) included a single infected baby. None of the 30 *S. aureus* strains recovered was resistant to meticillin. Molecular characterisation distributed the 30 MSSA isolates into eight PFGE patterns (A to H). The majority of the isolates ($n=20$, 67%) belonged to two major clones: A (spa type t1228 and ST5, $n=11$) and B (t012 and ST30, $n=9$). Although none of the isolates was PVL positive, all except PFGE pattern B strains were positive for LukE-LukD and gama-hemolisin variant determinants.
In two episodes, isolates belonging to the same PFGE type, but a different subtype, were recovered from both a baby and a HCW (A1, A2 in episode II and B4, B5 in episode X, respectively). No identical isolates from babies and parents and/or environment were found in the same episode. Nevertheless, a HCW isolate from episode II showed the same PFGE subtype (B1) of the babies' isolates in episodes I and VII and a similar type with isolates from babies in episodes VI (B3) and X (B4). However, no direct contact was reported between the four infected babies and this HCW. In addition, in episode VIII the baby was infected with the same strain (PFGE A3) recovered from a HCW and the environment in two anterior episodes (III, VI).
Conclusions: Our data suggests that a *S. aureus* transmission route could be traced between a HCW and the babies in two infection episodes (II and X). Highly related isolates belonging to two major clones were periodically recovered during epidemiologically unrelated infection episodes, which might indicate that these strains are endemic at the NICU.

P654 **The search and destroy strategy does prevent spread and long-term carriage of MRSA; results from household screening following a ST22 (E-MRSA 15) outbreak**

S. Böcher, M. Knudsen, C. Reese, H. Høgsted, P. Schouenborg, R.L. Skov (Copenhagen, Vejle, DK)

Objectives: From November 1, 2002 to December 31, 2005 440 persons were infected/colonised with MRSA ST22 during a hospital outbreak in Vejle County, Denmark.
This study was made to define the carriage rate, treatment outcome and spread of MRSA in households of previous ST22 infected/colonised patients and hospital staff.
Methods: The household visits were carried out from December 2006 to March 2007 and included samplings from all household members and pets as well as from the environment. Household members were sampled from nose, tonsils, urine and skin lesions; pets were sampled from nose, anus and skin lesions; and the environment from telephone, favourite chair, toilet flush handle, TV remote control and skirting board by the bed. Swabs (Regular flocked swabs, Copan, Italy) from human and animal samples were incubated in TSB (SSI diagnostics, Denmark). PCR positive broths were sub-cultured on blood agar (SSI) for final ID and susceptibility testing.
Urine samples were cultured on Chromogenic MRSA agar (Oxoid, UK). Environmental sampling was performed with Biotrace Dipslides (Biotrace, UK). Isolates suspected to be MRSA were confirmed and typed using mecA, SCCmec and spa PCR.
Following household visits, MRSA positive households received cleaning instructions, MRSA eradication treatment and follow up according to local MRSA-guidelines.
Results: Samples were obtained from 102 out of 251 households; 88 (45%) patients, 15 (27%) hospital staff, plus 45 relatives of patients, 22 relatives of hospital staff and 31 pets. 20 MRSA positive persons were identified; 16 patients (15 ST22, 1 ST5) and 4 patient relatives (2 ST22, 2 ST5). All households of hospital staff were negative. The 31 pets from 23 households were also negative. MRSA was found in tonsils (80%), nose (74%), and in urine (16%); from catheterised patients only. MRSA was found in the environment of 4 presently positive, long-term MRSA ST22 carriers. 88% of the positive patients had previously received MRSA treatment. After re-treatment 4 patients were still positive: 2 with catheter, 1 with fistulas and 1 with alcohol abuse. The mean follow-up time was 11 months.
Conclusion: Follow-up on 103 previously MRSA ST22 positive patients/hospital staff showed that 20% of patients were positive; following re-treatment 95% were MRSA negative. The environment was a possible reservoir for re-colonisation in households of long-term and present carriers. No pets were found positive for MRSA.

P655 **Meticillin-resistant *Staphylococcus aureus* in young dogs and their owners**

M. Corrente, M. D'Abramo, F. Latronico, G. Greco, M. Marinaro, V. Martella, C. Buonavoglia (Valenzano, Rome, IT)

Objectives: An outbreak of neonatal mortality in dogs by a Meticillin-resistant *Staphylococcus aureus* (MRSA) is reported and the possible role of the owners as reservoirs of the infection is evaluated.
Case presentation and results: A female boxer at the first pregnancy gave birth to 12 pups without post-partum complications. As the dam developed agalactia, the pups were fed with artificial milk. The entire litter died within 10 days with signs of severe septicaemia. The bitch was living with a male boxer and both the dogs tested negative by seroagglutination for Brucella canis. One pup was sent to the laboratory for necropsy. Multifocal haemorrhagic lesions in various organs were observed. Tissue samples from the organs were subjected to investigations for viral and bacterial pathogens. By PCR, the samples tested negative to Canine Herpesvirus and Canine Parvovirus type 1. By bacteriological analysis, a strain of *S. aureus* was isolated in purity from heart, liver, spleen and kidney of the pup. The strain was found to be Meticillin resistant by a PCR assay specific for the mecA gene.
In order to investigate the source of the infection by MRSA, bacteriological analysis was extended to the dogs and persons living in the household. Swabs from several parts of the body were taken from the parents of the pups, from the 2 owners (a man and his wife), and from a relative, a woman who occasionally looked after the animals. The man and this woman worked as medical attendants of the same hospital. From all the samples MRSA was isolated, for a total of 17 strains.
The strains exhibited the same pattern of antimicrobial susceptibility, being resistant to more than 3 classes of non-β-lactams. All the strains possessed the staphylococcal chromosome cassette mec (SCCmec) II and lacked the Panton valentine leucocidin (PVL) genes. In addition, they displayed the same pulsotype, thus suggesting a clonal origin.
Conclusion: From dogs and humans living in the same household a single MRSA clone was isolated displaying typical pattern of HA-MRSA (multidrug resistant, SCCmec II type and PVL negative). Since two of the persons were medical attendants in a hospital, and the dogs had no contact with other animals or persons, we hypothesise that a MRSA clone spread from the hospital and got adapted to the household, causing a fatal infection in the pups.

P656 **Prevalence of meticillin-sensitive and resistant *S. aureus* nasal colonisation in healthcare workers in a tertiary hospital**

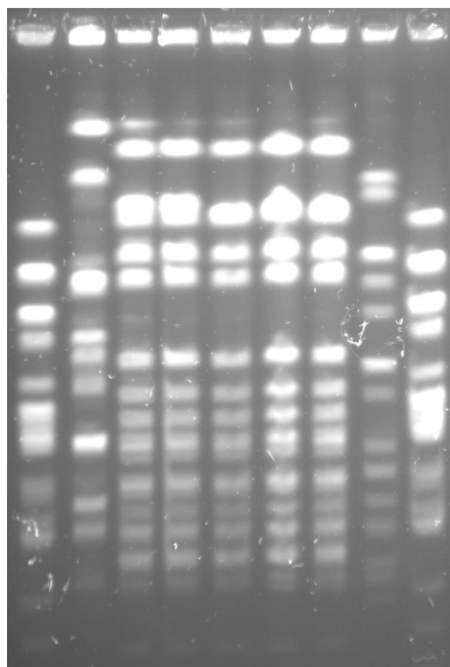
V. Spyropoulos, H. Moraitou, M. Makarona, F. Havouti, N. Tsagarakis, D. Kalikantzaros, N. Lolis, S. Kanavaki (Athens, GR)

Objectives: The aim of this study was to establish the rates of nasal carriage in medical and nursing personnel of a tertiary care Hospital for both meticillin-sensitive (MSSA) and resistant (MRSA) *S. aureus*, in order to perform infection control measures, if necessary. The MRSA strains isolated were further tested by PCR for the presence of mecA and pvl genes.
Methods: A total of 220 nasal swabs were taken from 111 healthcare workers participating in the study, of which 43 were medical (21 ICU clinicians and 22 medical microbiology doctors) and 68 non-medical staff (34 nursing and 34 laboratory personnel). All swabs were cultured onto Columbia Blood agar (Oxoid, UK) and ChromID MRSA agar (Biomerieux, France). All unique-patient *S. aureus* isolates were identified by VITEK 2 automated system and were further tested for antibiotic susceptibility by both VITEK 2 system as well as Kirby-Bauer disk diffusion method. All *S. aureus* isolates were further tested for the presence of mecA and pvl genes by PCR (Genotype *Staphylococcus*, Hain Germany).
Results: In total, the prevalence of *S. aureus* nasal carriage was 18.0%. MSSA carriage was 12.6% and MRSA 5.4%.
MSSA prevalence was 11.6% (5/43) among medical personnel and, in particular, 9.1% (2/22) for laboratory doctors and 13.6% (3/21) for ICU clinicians. MSSA prevalence among non-medical staff, was 13.2% (9/68) and in particular, 17.6% (6/34) for laboratory personnel and 8.8% (3/34) for ICU nursing personnel.
MRSA prevalence was 4.7% (2/43) among medical personnel, and in particular, 4.5% (1/22) for laboratory doctors and 4.7% (1/21) for ICU clinicians. MRSA prevalence among non-medical staff was 5.9% (4/68), 0% for laboratory personnel and 11.8% (11/34) for ICU nursing personnel.
All MRSA strains were found positive for mecA gene, by PCR, while only one strain was found to be pvl positive (5%, 1/20).
Conclusion: The prevalence of MSSA as well as MRSA nasal carriage is within the expected rates, as commonly mentioned in the literature. The highest MSSA rates were found among non-medical laboratory staff, while, the highest MRSA rates were found among ICU nursing personnel. Among medical personnel, the prevalence rates were similar, for both MSSA and MRSA. This study is a part of an ongoing epidemiological surveillance conduced in our Hospital, in order to eliminate MRSA carriage.

P657 Meticillin-resistant *Staphylococcus aureus* nasal carriage in an army recruits population: prevalence and genotyping

U. Demirpek, T. Haznedaroglu, M. Ozyurt, B. Bozdogan (Ankara, Istanbul, Aydin, TR)

Objective: Although MRSA strains are strictly related to hospital setting community-acquired meticillin-resistant *Staphylococcus aureus* (CA-MRSA) is emerging worldwide. MRSA carriage is important for dissemination of CA-MRSA infections. The aim of this study was to determine the prevalence of MRSA nasal carriage among army recruits who are from different geographic areas of the country.
Methods: A total of 4843 army recruits were examined by nasal cultures. *Staphylococcus aureus* strains were characterised and identified by conventional methods. Antimicrobial susceptibilities were tested by disk diffusion method and all MRSA strains were typed by SCCmec and PFGE. Potential risk factors for colonisation have been noted down using a questionnaire; such as admissions to hospital, antibiotics usage, hometown, educational level, annual salary, job.



Results: *Staphylococcus aureus* strains were isolated from 552 (12%) of 4843 participants. Seven out of 552 *S. aureus* were resistant to meticillin. Overall community-associated MRSA carriage rate was 1.3%. Presence of mecA gene was confirmed in all 7 strains by mecA PCR. SCCmec typing and PFGE typing showed that 5 isolates were type III and A pulse-type, and the remaining 2 strains were type II and B and C pulse-types. The cases are found out to be admitted to hospital and/or used antibiotics.
Conclusion: MRSA is emerging in community level. Army is one of the risk group for MRSA dissemination and infection. The carriage level was 1.3% similar to carriage rates in previous studies from Turkey. The major A clone obtained from 5 of 7 soldiers were related to a hospital clone in a military hospital in the same area. Large scale studies should be done to evaluate presence a CA-MRSA clone other than hospital clones.

P658 Genotypic characterisation of *Staphylococcus lugdunensis*

F. Laich, N. Batista, M. Lara-Pérez, E. Pérez-Roth, B. Rivero-Pérez, S. Méndez-Álvarez (S/C de Tenerife, ES)

Background: *Staphylococcus lugdunensis* is a coagulase-negative staphylococcal species. Until the 90s, association of these bacteria to human pathogenic processes was considered a rare clinical event but during last years infections by this agent have considerably increased and now it has to be considered as a possible cause of breast abscesses, peritonitis, infected joint prostheses, osteomyelitis, discitis, septic arthritis and pacemaker infections.
Objectives: The main goal of this study was to perform the genotypic characterisation of *S. lugdunensis* clinical isolates recovered by the Microbiology Service of the Hospital Universitario Ntra. Sra. de Candelaria (Tenerife, Spain) during an eight year surveillance period (1999–2007).
Methodology: Seventy-five isolates recovered from 70 patients were firstly identified by classic microbiology biochemical and phenotypic methods. Identification was then confirmed by sequencing 16S rDNA and rpoB genes encoding the beta-subunit of RNA polimerase. After identification, each isolate was analysed by the following methods: (i) Multiplex PCR (MPCR) detection of the genes mecA and ileS-2, encoding meticillin and high-level mupirocin resistance, respectively; (ii) PCR amplification of the ribosomal internal spacer transcript (ITS-PCR), and (iii) Pulsed-Field Gel Electrophoresis macrorestriction patterns (RFLP-PFGE).
Results: MPCR amplification of the genes mecA and ileS-2 was negative for all the 75 isolates. ITS-PCR patterns permitted to distinguish 18 different genotypes, being types D and E the two major ones constituting the 25.3 and 18.6% of the isolates, respectively. The RFLP-PFGE analysis showed higher discriminative power than ITS-PCR and allowed to distinguish 34 genotypes. PFGE type 11 was the one including the higher number of isolates (8, 10.6%).
Conclusions. This study permits to conclude the existence of a high genotypic diversity within the species *S. lugdunensis*. We may conclude that the heterogeneity observed is greater than previously reported.

P659 Non-invasive coagulase negative staphylococci: population variability and meticillin resistance

N.A. Faria, D.C. Oliveira, H. Lencastre, H. Westh (Oeiras, PT; New York, US; Copenhagen, DK)

Objectives: Staphylococcal chromosomal cassette mec (SCCmec) is a large heterologous mobile genetic element carrying the mecA gene. This gene is the central element of meticillin resistance (MR) in staphylococci and has largely been studied in *Staphylococcus aureus*. The origins, reservoirs and dissemination routes of SCCmec elements are not well understood, although their elucidation might improve infection control measures targeting reduction of β-lactam resistance. For that purpose, it is necessary to characterise SCCmec elements circulating in staphylococci other than *S. aureus*, both in the hospital and community settings.
Methods: Five-hundred and twenty eight non-invasive coagulase negative staphylococci (CNS) were collected among 67 Danish volunteers from three different patient groups: (i) children $\leqslant$ 2 years; (ii) patients from a Dermatology department; and (iii) patients previously identified as community-onset MR *S. aureus* (CO-MRSA) carriers. Susceptibility tests for a panel of eight antibiotics were performed using disc diffusion. Internal transcribed spacer PCR (ITS-PCR) was performed in order to confirm VITEK 2 identification and to clarify unspeciated isolates.
Results: MR-CNS was found associated to patients from the dermatology department and to children $\leqslant$ 2 years (50% resistant isolates in these groups versus 4% MR-CNS isolates in CO-MRSA carriers). Fifteen different species were identified among the 528 CNS, out of which 15 (3%) could not be identified by VITEK 2. ITS-PCR was useful for the speciation of more exotic CNS isolates.
Conclusion: Resistance patterns showed that reservoirs of MR-CNS were associated with patients with hospital contact rather than CO-MRSA patients. In addition, the reservoirs of SCCmec elements among CNS isolates were more diverse than expected, since MR was observed in 11 of the staphylococci species recovered: *S. epidermidis* (40%), *S. haemolyticus* (74%), *S. hominis* (42%), *S. saprophyticus* (44%), *S. simulans* (20%), *S. xylosus* (25%), *S. warneri* (4%), *S. capitis* (45%), *S. cohnii* (50%), *S. caprae* (14%), and *S. kloosii* (20%). The ongoing

characterisation of the SCCmec elements in this collection will help to elucidate the genetic relationships and dissemination routes of these mobile genetic elements between *S. aureus* and CNS isolates and among CNS isolates.

P660 MRSA carriage in healthcare personnel in contact with farm animals

M.W.H. Wulf, E. Tiemersma, J. Kluytmans, A.C.A.P. Leenders, J. Berkhout, A. Voss (Veldhoven, De Bilt, Breda, Den Bosch, Venlo, Nijmegen, NL)

Objective: In the Netherlands, veterinarians in contact with pigs and pig farmers were found to have a higher risk of meticillin resistant *S. aureus* (MRSA) carriage than the general population. Isolates of closely related spa-types, corresponding to MLST type ST398 were found in pig farmers, pig veterinarians and pigs. The objective of this study was to investigate if contact with pigs and veal calves or other livestock is a risk factor for MRSA carriage in Dutch healthcare workers (HCW).
Design: Healthcare workers in four general hospitals and one university hospital were asked to fill in questionnaires about contact with animals and take MRSA cultures of their throat and nares. Cultures of all HCW in contact with livestock were processed and for each HCW in contact with pigs or veal calves, screening cultures from a minimum of two HCW with no contact with livestock were processed.
Results: 77 of 1721 HCW (4.4%) reported direct or indirect contact with pigs and/or veal calves, 145 reported contact with other livestock animals. Two MRSA-positive HCWs were found; one in contact with veal calves and one in the control group. The MRSA carriage rate in the group in contact with pigs and veal calves was 1.7% (95% CI, 0.07%-8.0%) and in the control group (category 3) 0.15% (95% CI, 0.01–1.0%). No carriers were found among HCW in contact with other livestock (95% CI 0–3.2%).
Conclusions: An estimated 3% (CI 2.6–4.1%) of hospital staff working in Dutch hospitals with a rural adherence region belong to a high risk group for MRSA carriage according to the Dutch guidelines. While MRSA carriage in HCW in contact with livestock is higher (10-times) than in other HCW the difference is not statistically significant.

Networks for surveillance of antimicrobial resistance

P661 Five years of Belgian MIST (meropenem information on bacterial susceptibility testing) surveillance: 2001–2005

D. Govaerts, G. Coppens, D. Fameree, B. Masschelin, F. Meunier, C. Sion, P. Turner, G. Vandenhoven (Montigny-le-tilleul, Genk, Charleroi, Turnhout, La Louvière, Huy, BE; Macclesfield, UK; Brussels, BE)

Objectives: The activity of meropenem and 6 comparators was studied in the MIST trial, on a total of 2.553 isolates (706 Gram-positives and 1.847 Gram-negatives) from 6 general non teaching hospitals in Belgium, collected from 2001 to 2005.
Materials and Methods: Centres collected consecutively up to 50 and 75 unduplicated, aerobic Gram+ and Gram– isolates respectively from patients admitted in ICU, haematology and general wards. CLSI methods and E-tests were used for susceptibility testing. ESBL and AmpC production were confirmed by at least a ⩾3log2 reduction in ceftazidime MIC in the presence of clavulanate and a ceftazidime MIC > 8mg/l not lowered by the presence of clavulanate respectively.
Results: *S. aureus* (n = 237) was the most frequently isolated Gram+ bacteria with 98–100% susceptibility for the carbapenems. Among the Enterobacteriaceae (n = 1371), meropenem was the most active antibiotic (99.9%), followed by imipenem (98.5%), cefepime (98.3%) and amikacin (93.1%). Lower susceptibility rates were observed for piperacillin–tazobactam (83.1%), ceftazidime (80.2%) and ciprofloxacin (75.8%). More than 50% of *E. aerogenes* isolates (n = 232) were resistant to ceftazidime, piperacillin–tazobactam and ciprofloxacin, while the carbapenems and cefepime were extremely active (>95% susceptibility). Susceptibility rates among all Enterobacteriaceae remained stable for all antibiotics tested between 2001 and 2005. The prevalence of ESBL-producing isolates varied from 1.7 to 3.9% for all Enterobacteriaceae, from 0 to 4.3% for *E. coli* (n = 322), 0 to 9.5% for *K. pneumoniae* (n = 160) and 0 to 4.9% for *E. aerogenes*. The prevalence of AmpC producers among *E. aerogenes* isolates varied from 0 to 42%. Susceptibilities of ESBL and AmpC producers to carbapenems varied between 98–100%.
Against *P. aeruginosa* isolates (n = 273), the rank order of susceptibilities during the study period was: meropenem (88.3%), ceftazidime (87.9%), piperacillin–tazobactam (86.1%), amikacin (85.7%), imipenem (84.2%), cefepime (77.9%) and ciprofloxacin (76.9%). Susceptibility rates for *P. aeruginosa* remained stable for all antibiotics tested, excepted cefepime, which declined between 2001 and 2005.
Conclusions: During the study period, the carbapenems and cefepime were the most active agents against the Enterobacteriaceae, including ESBL and/or AmpC producers. Meropenem and ceftazidime were the most active agents against *P. aeruginosa*.During 5 years of Belgian MIST surveillance, susceptibility rates for meropenem remained stable.

P662 Bacterial resistance surveillance in China: a report from Mohnarin, 2004–2005

Y-H. Xiao, J. Wang, Y. Li (Beijing, CN)

Objective: To establish the nationwide antimicrobial resistant investigation network and get bacterial resistance information in China.
Methods: The clinical bacterial isolates were collected from 17 network hospitals around China, antibacterial minimal inhibitory concentration (MIC) were determined by standard agar dilution method recommended by CLSI.
Results: A total of 4075 isolates were collected from 17 hospitals in 15 cities. The results of MICs showed the followings: The detection rates of oxacillin-resistant *Staphylococcus aureus* and *Staphylococcus epidermidis* were 62.9% and 82.89% respectively. Penicillin non-sensitive *Streptococcus pneumoniae* were 40.7%, which included 10.5% penicillin-resistant strains and 30.2% penicillin-intermediate strains 40.7%. 5 strains of Enterococci were vancomycin-intermediate, but all the strains were sensitive to teicoplanin. All Staphylococci were susceptible to glycopeptides. Macrolide-resistance was a predominant phenomenon for Gram-positive cocci. Enterobacteriaceae were obviously resistant to the third generation cephalosporin except for ceftazidime, and the resistance rates were 20%-70%. Carbapenems still remained highly activity against all the target bacteria. In addition, latamoxef, piperacillin / tazobactam, cefoperazone / sulbactam and cefepime were all active against Enterobacteriaceae and the resistant rates of which was bellow 10%. 10.6% of *Pseudomonas aeruginosa* and 10.4% of *Acinetobacter baumannii* were resistant to imipenem, and most of them were multidrug resistant. Combinations of β-lactam/β-lactamase inhibitor and fluoroquinolones also had potent antibacterial activity against non-fermenters. Amikacin was active against Enterobacteriaceae and *P. aeruginosa*.
Conclusion: meticillin-resistant Staphylococci, penicillin non-sensitive *S. pneumoniae*, macrolides-resistant Gram-positive cocci, cephalosporin-resistant Enterobacteriaceae, multidrug resistant nonfermenters and fluoroquinolone-resistant *E. coli* were the predominant problems. No glycopeptides-resistant *Staphylococcus* was found and glycopeptides-resistant Enterococci remained seldom.

P663 Resistance surveillance of bacterial pathogens from North American patients hospitalised with pneumonia: a 10-year report from the SENTRY Program (1997–2006)

T. Fritsche, G. Moet, H. Sader, R. Jones (North Liberty, US)

Objectives: The emergence of resistance (R) among pneumonia pathogens has resulted in increasing reliance upon fluoroquinolones and

advanced-generation β-lactams, including carbapenems. We summarize the prevalence and susceptibility (S) profiles of bacterial pneumonia pathogens collected during ten years of the SENTRY Antimicrobial Surveillance Program (1997–2006).

Methods: Participating North American medical centres (⩾24/year) referred 50 consecutive, non-duplicate pathogens (19,406 isolates) from lower respiratory tract sites determined to be the probable cause of pneumonia in hospitalised patients (community and nosocomial in origin). Isolate identifications were confirmed and susceptibility testing was performed using CLSI reference methods at a central laboratory (JMI Laboratories, North Liberty, IA).

Species (no. tested)	Antimicrobial agent	%R 1997	2002	2006
SA (5774)	OXA	39.4	45.9	61.4
PSA (3764)	CAZ	19.0	12.6	17.4
	IMP	8.0	7.3	13.6
	CIP	15.3	23.8	23.0
KSP (1541)	CRO	1.2 (9.3)	6.9 (21.7)	5.3 (12.6)
	IMP	0.0	0.4	3.2
	CIP	3.2	5.8	9.5
SPN (1282)	PEN	9.2	16.4	11.8
	ERY	14.5	23.7	29.4
EBS (1222)	CRO	13.2	7.8	17.9
	CIP	3.4	3.9	7.7
EC (798)	CRO	1.6 (7.0)	1.0 (7.2)	7.7 (7.7)
	CIP	1.6	9.3	30.8
ASP (540)	CAZ	29.5	39.0	58.8
	IMP	3.3	5.1	14.7
	CIP	34.4	54.2	73.5

*Numbers in parentheses are ESBL-phenotype rates (% ⩾2 μg/ml).

Results: Selected pathogens with unique or emerging R characteristics are in the Table. The 10 ranked pathogens comprised 90.4% of all isolates and included: *S. aureus* (SA; 28.1%) > *P. aeruginosa* (PSA; 19.4%) > *Klebsiella* spp. (KSP; 7.9%) > *H. influenzae* (7.7%) > *S. pneumoniae* (SPN; 6.6%) > *Enterobacter* spp. (6.3%) > *E. coli* (EC; 4.1%) > *Serratia* spp. (3.8%) > *S. maltophilia* (3.6%) > *Acinetobacter* spp. (ASP; 2.8%). Among Gram-positive species, R emergence was notable for SA (oxacillin [OXA] -R currently 61.4%; ERY-non-susceptibility [NS], 69.2%) and SPN (ERY-R, 29.4%; PEN-R, 11.8%). Among enterics, CIP-R (30.8% for EC in 2006) and ESBL-phenotype rates (KSP and EC; ranges 6.7–23.9% and 3.8–11.7%, respectively) have increased considerably. An increase in IMP-R in KSP primarily results from a continued east coast epidemic of clonal strains expressing serine carbapenemase (primarily KPC-2) enzymes. While CAZ- and IMP-R among PSA has increased, R to CAZ and fluoroquinolones have become predominant among ASP; only polymyxins remain largely S (>97%).

Conclusions: Although temporary resistance declines were detected among some North American pneumonia pathogens, all showed increasing resistance to most class agents during the monitored period. Continued longitudinal comparisons of emerging pathogens and changing susceptibility profiles are critical elements in guiding empiric therapies and epidemiologic interventions.

P664 Escalating resistance among non-fermentative Gram-negative bacilli: Report from the North American SENTRY Antimicrobial Surveillance Program (1997–2006)

H. Sader, T. Fritsche, M. Stilwell, R. Jones (North Liberty, US)

Objective: Systemic infections due to non-fermentative Gram-negative bacilli (NFB) are often difficult to treat because of rising resistance rates and limited therapeutic options. We evaluated the occurrence and antimicrobial susceptibility profiles of NFB pathogens collected over 10 years of the SENTRY Antimicrobial Surveillance Program in North America.

Methods: Consecutive clinically significant and non-duplicate NFB strains (12,435 total) were submitted from medical centres in the USA (⩾25) and Canada (5; 1997–2002 only) and susceptibility tested by broth microdilution using CLSI methods and interpretive criteria at a central laboratory (JMI Labs, North Liberty, Iowa). Specifically, changes in susceptibility rates were analysed over time. Carbapenem-resistant *P. aeruginosa* (PSA) and *Acinetobacter* spp. (ASP) were screened for metallo-β-lactamase (MBL) enzyme production by a disk approximation method or by Etest (AB BIODISK, Solna, Sweden).

Organism (no. tested)	MIC_{50} (μg/ml)/% susceptible[a] Amikacin	Ceftazidime	Imipenem	Levofloxacin	TMP/SMX
Acinetobacter spp. (1,779)	⩽4/84	8/59	0.25/91	⩽0.5/62	⩽0.5/74
Aeromonas spp. (102)	⩽4/97	⩽1/95	0.5/97	⩽0.5/99	⩽0.5/87
A. xylosoxidans (118)	>32/14	4/86	2/92	2/57	⩽0.5/90
B. cepacia (88)	>32/10	4/74	4/51	2/60	⩽0.5/88
P. aeruginosa (8,420)	⩽4/96	2/83	1/87	⩽0.5/74	>2/46
P. fluorescens/putida (155)	⩽4/96	4/90	1/87	⩽0.5/85	2/52
S. maltophilia (1,309)	>32/13	8/54	>8/1	1/83	⩽0.5/99

[a]Based on CLSI breakpoints for *Acinetobacter* spp., *P. aeruginosa* and *S. maltophilia*.
TMP/SMX = trimethoprim/sulfamethoxazole.

Results: The most commonly recovered non-fermentative Gram-negative bacilli were PSA (68%), ASP (14%) and *S. maltophilia* (SM; 11%). Polymyxin B (tested 2001–2006) was very active against PSA and ASP (⩾99% susceptible), but displayed more limited activity against other NFB. Tigecycline (2002–2006) exhibited good activity (MIC50 / % at ⩽2 mg/L) against ASP (0.5/92) and SM (0.5/93), but limited potency against PSA. The activities of other antimicrobials are in the Table. Susceptibility patterns of PSA and SM remained very stable during the decade. In contrast, ASP susceptibility rates decreased for most agents, including (1997/2006 % susceptible): imipenem (94/78), amikacin (92/80), gentamicin (77/61) and ciprofloxacin (73/53). Many imipenem-non-susceptible ASP strains (77%) were from three medical centres in the New York City area, the remaining were from 13 centres and collected mainly in 2006 (61%). Imipenem-resistant PSA strains were widely distributed geographically. No MBL-producing strain was identified among ASP and PSA isolates.

Conclusions: Therapeutic options to treat NFB infections are becoming increasingly limited secondary to progressively rising resistance rates. Continued NFB surveillance remains necessary to optimise empiric antimicrobial therapy, especially for the less frequently isolated and difficult to test species.

P665 Trends in prevalence and antimicrobial susceptibilities among skin and skin structure infection pathogens in North America: Report from the SENTRY Program (1997–2005)

G. Moet, R. Jones, H. Sader, T. Fritsche (North Liberty, US)

Objectives: Rising resistance (R) rates being observed globally in skin and skin structure infection (SSSI) pathogens are challenging accepted approaches to empiric management. We present a nine year summary of the prevalence and susceptibility (S) trends of bacterial pathogens producing SSSI collected from USA and Canadian medical centres participating in the SENTRY Antimicrobial Surveillance Program.

Methods: Participating North American (NA) medical centres were directed to send 50 consecutive, non-duplicate SSSI pathogens/year. USA (⩾21) and Canadian (5) medical centres submitted isolates for the years 1997–2002; USA sites only participated during 2004–2005. Isolate identifications were confirmed and susceptibility testing was performed using CLSI reference methods at a central laboratory (JMI Laboratories, North Liberty, IA).

Results: The top 7 ranked pathogens comprised 85.2% of the total (8,520 isolates; see Table) with *S. aureus* (SA) being predominant, ranging from 40.4–53.1% between years. Other ranking pathogens included *P. aeruginosa* (PSA), *Enterococcus* spp. (ENT), and *E. coli* (EC) which were second to fourth each year except in 2004, when ENT and PSA reversed rank. Prevalence of beta-haemolytic streptococci (BHS) varied from fifth in 1998, ninth in 2000, then fifth again in 2004/2005. The all-years NA MRSA rate was 35.9% (9% in Canada) and ranged from 31.3 to 56.2% among USA census zones. Highest ENT vancomycin R (VAN-R; 16.5%) was found in 2005 and highest erythromycin R rate (25.8%) in BHS was found in 2004. Trending increases in fluoroquinolone (FQ) R rates among EC and *Klebsiella* spp. (KSP) reached 24.4 and 12.8%, respectively. ESBL phenotype rates for EC (12.8%) peaked in 2004 and for KSP (20.5%) in 2005. In contrast to these changes, ceftazidime-, imipenem- and levofloxacin-R rates for PSA (higher in earlier years) have trended downwards.

Organism (no.)	R pattern	% R All years	% R (range)
SA (3,862)	MRSA	35.9	24.0–49.4
PSA (908)	Imipenem (IMP)-R	6.1	1.1–9.8
	Ceftazidime (CAZ)-R	10.0	7.8–13.1
	Levofloxacin (LEV)-R	18.9	15.7–22.5
ENT (748)	Vancomycin (VAN)-R	12.4	7.6–16.5
EC (610)	CAZ-R	2.8	0.0–7.0
	LEV-R	9.3	2.4–24.4
EBS (409)	CAZ-R	17.8	7.6–25.5
BHS (379)	Erythromycin (ERY)-R	19.8	8.8–25.8
KSP (344)	CAZ-R	5.2	0.0–17.9
	LEV-R	3.2	1.4–12.8

Conclusions: SSSI pathogen prevalence has changed minimally since 1997 (exception, BHS). MRSA rate differences are notable between countries and between USA census zones. R rates for ENT (VAN-R), and EC and KSP (FQ and ESBLs) are increasingly of concern whereas R among key agents targeting PSA have improved from earlier SENTRY surveillance periods. Continued surveillance monitoring of these trends, both locally and globally, provides useful information for empiric management of SSSI and in assessing needed changes to antimicrobial therapy guidelines.

P666 Meropenem, β-lactam with the highest activity against Gram-negative isolates from the intensive care unit – Part of the MYSTIC (Meropenem Yearly Susceptibility Test Information Collection) Programme, 1997–2007

J.A. Patzer, D. Dzierzanowska, A. Pawinska, P.J. Turner (Warsaw, PL; Macclesfield, UK)

Objectives: MYSTIC (Meropenem Yearly Susceptibility Test Information Collection) is a longitudinal surveillance study comparing the in vitro activity of meropenem (MEM) and other antibiotics against bacterial strains from clinical units that use MEM for treatment. The aim of this analysis was to assess the in vitro activity of MEM and eight other antibiotics against Gram-negative isolates from a paediatric ICU.
Methods: 1300 Gram-negative isolates were obtained from various clinical specimens of children hospitalised in the ICU in 1997–2007. The isolates were identified using conventional methods. The Minimum Inhibitory Concentrations (MICs) of MEM, imipenem (IPM), piperacillin+tazobactam (TAZ), cefotaxime (CTX), ceftazidime (CAZ), cefepime (CPE), gentamicin (GM) and ciprofloxacin (CIP) were determined using the NCCLS agar dilution method.
Results: The collection of Gram-negative isolates included *Escherichia coli* (n = 187), *Enterobacter cloacae* (n = 233), *Klebsiella oxytoca* (n = 118), *Klebsiella pneumoniae* (n = 211), *Serratia marcescens* (n = 50), *Acinetobacter baumannii* (n = 137), *Pseudomonas aeruginosa* (n = 253) and other species (n = 111). MEM, IPM and CIP were the most active against 94.2%, 92.2% and 95.2% of isolates, respectively. The MIC90 (mg/L) of MEM was nearly identical in 1997 and 2007. It was equal to 0.06 for Enterobacteriaceae, 1.0 for *A. baumanii* and 8.0 for *P. aeruginosa*. The MIC90 of IPM was equal to 0.25 for Enterobacteriaceae, 1.0 for *A. baumannii* and 16 for *P. aeruginosa*. During 1997–2007, among Enterobacteriaceae were only found two *E. cloacae* and one *E. amnigenus* resistant to carbapenems. Among carbapenem resistant *P. aeruginosa* isolates one strain producing metallo-β-lactamase VIM4 was found. The overall order of susceptibility of tested isolates to other β-lactams was CPE (85.8%) > TAZ (75.2%) > CAZ (72%) > CTX (53.6%). Susceptibility to GM characterised 66.9% of isolates. The incidence of extended spectrum β-lactamase producers among Enterobacteriaceae decreased from 39.7% in 1997 to 20.7% in 2007.
Conclusions: MEM, IMP and CIP were the most active antibiotics (>90% susceptibility) against Gram-negative isolates, with no observed reduction in activity over 11 years. A greater proportion of *P. aeruginosa* isolates were susceptible to MEM than to IPM. Carbapenems, such as MEM, can be used as an option in the first line therapy of nosocomial infections in the ICU.

P667 *Acinetobacter* spp. infections: the Latin American scenario in the SENTRY Antimicrobial Surveillance Program (1997–2006)

A. Gales, D. Xavier, S. Andrade, R. Jones, H. Sader (Sao Paulo, BR; North Liberty, US)

Objectives: To evaluated the frequency of occurrence, the antimicrobial susceptibility profile and the temporal evolution of antimicrobial resistance among *Acinetobacter* spp. isolated in Latin America. *Acinetobacter* spp. is an important nosocomial pathogen in Latin America and exhibits high rates of acquired resistance to many antimicrobial agents.
Methods: Consecutive non-duplicate bacterial pathogens were collected in the last decade (1997–2006) from hospitalised patients in 10 Latin American medical centres (7 countries). The antimicrobial susceptibility profile to >20 antimicrobial agents was evaluated by CLSI broth microdilution methods and interpreted by CLSI M100-S17 (2007) or US-FDA package insert criteria for Enterobacteriaceae (tigecycline).
Results: A total of 1,807 isolates were collected during the 10-year period. The highest number of isolates were collected from Brazil (53%) > Argentina (19%) > Chile (14%) and Mexico (6%). Most isolates were collected from bloodstream (57.7%) followed by respiratory tract (31.9%) infections. The activities of selected drugs are shown in the table. Polymyxin B, tigecycline and imipenem demonstrated the highest in vitro activity against *Acinetobacter* spp. A significant increase ($p < 0.05$) in the resistance rates for imipenem (6.7–24.4%), meropenem (6.7–24.3%), cefepime (38.3–54.8%), ceftazidime (56–72.1%), amikacin (55.4–68.2%) was observed when comparing 1997 and 2006 results.

Antimicrobials	MIC (mg/L)		% Susceptible	% Resistant
	MIC_{50}	MIC_{90}		
Amikacin	>32	>32	34.9	59.5
Cefepime	16	>16	35.1	49.7
Ceftazidime	>16	>16	27.9	63.7
Ciprofloxacin	>2	>4	30.5	69.0
Imipenem	1	>8	83.5	15.3
Meropenem	2	>8	81.0	15.3
Polymyxin B	0.5	1	98.1	1.9
Tigecycline[a]	0.5	2	98.1	0.0

a. Not tested in all years.

Conclusions: Polymyxin B remains the most active drug against *Acinetobacter* spp. in the Latin American countries evaluated by the SENTRY Program and tigecycline was also active. An important reduction in the susceptibility rates to some broad-spectrum antimicrobials, including the carbapenems, was observed, limiting therapeutic options available.

P668 Drug resistance amongst European isolates of *Escherichia coli* isolated from the MYSTIC Programme 2007

P. Turner (Macclesfield, UK)

Objectives: In a time where resistance amongst the Enterobacteriaceae tends to be dominated by *Klebsiella* and *Enterobacter* species it is useful to also examine the susceptibility patterns expressed by *Escherichia coli* – still the commonest Gram-negative organism involved in nosocomial infections.
Methods: During 2007 a total of 496 clinically significant, non-copy isolates of *E. coli* were obtained from European centres involved in the MYSTIC (Meropenem Yearly Susceptibility Test Information Collection) Programme. These were examined using CLSI methodology and associated interpretive criteria in order to ascertain their susceptibility to a range of compounds. Extended-spectrum β-lactamase (ESBL) producers were confirmed by synergy with clavulanic acid and AmpC production by lack of synergy with this compound.
Results: See the table.

		% Susceptible*						
E. coli	n	MEM	IPM	CAZ	CPM	P+T	CIP	GM
All	496	99.8	100	84.9	90.6	88.7	76.4	84.6
ESBL	29	100	100	0	0	65.5	31	30
AmpC	13	100	100	0	61.5	53.9	61.5	100
R to CAZ/CIP	25	96	100	0	30	56	0	28.6
R to CAZ/CIP/GM	10	90	100	0	42.9	50	0	0

*CLSI criteria.
MEM: meropenem; IPM: imipenem; CAZ: ceftazidime; CPM: cefepime; P+T: piperacillin+tazobactam; CIP: ciprofloxacin; GM: gentamicin.

Conclusions: Whilst still at a low level ESBL (0.6%) and AmpC (0.3%) positive strains were isolated, and these were frequently also resistant to other classes of antibiotics (fluoroquinolones, aminoglycosides and β-lactam/β-lactamase combinations) as well as the cephalosporins. The carbapenems remain a useful therapy option against this type of isolate.

P669 Antimicrobial drug resistance in human non-typhoidal *Salmonella* isolates in Europe 2000–04: a report from the Enter-net international surveillance network

J. Threlfall, I. Fisher on behalf of the Enter-net participants

Objectives: To investigate the occurrence of resistance to antimicrobials in salmonella strains from humans in ten European countries over the five year period 2000–2004
Methods: The antimicrobial susceptibility test results of salmonella isolates received from ten countries – Austria, Denmark, England and Wales, Germany, Ireland, Italy, Luxembourg, The Netherlands, Scotland and Spain – that supplied data for all years between 2000 and 2004 were extracted from the Enter-net *Salmonella* database. Interpretation of sensitivity results had previously been harmonised throughout the Enter-net network. Descriptive and statistical analyses were undertaken using Microsoft Excel and Epi Info version six. Relative proportions were compared using the Chi-squared test for trend.
Results: Results of antimicrobial susceptibility testing for 134,310 isolates of non-typhoidal salmonellas from cases of human infection in ten European countries from 2000–04 has demonstrated an overall increase in the occurrence of resistance, from 57% to 66% over the period of study. In contrast multiple resistance (to four or more antimicrobial drugs) has declined from 18% to 15%. The most significant increase in resistance has been to nalidixic acid (14% to 20%), particularly in *Salmonella enterica* serovar Enteritidis (10% to 26%), the most common serovar over the period of study. For England and Wales this increase has for the most part been attributed to infections linked to contaminated eggs originating outwith the United Kingdom. For S. Typhimurium, the second most prevalent serovar, there has been an overall decline in the occurrence of resistance to ampicillin, chloramphenicol and tetracyclines, attributed to a decline in the occurrence of multiresistant S. Typhimurium DT 104. For S. Virchow, a serotype with a predeliction for invasive disease, there has been a substantive increase in resistance to most antimicrobials, attributed to the spread of drug-resistant strains associated with poultry.
Conclusion: Results indicate that the overall interpretation of susceptibility data from different countries ishould take into account both indigenous strains and also strains originating as a result of foreign travel and the importation of contaminated foods. Because of the widespread importation of foods, it is important that controls to reduce the emergence and spread of drug-resistant strains of *Salmonella* are internationally implemented.

P670 Evolution of antimicrobial susceptibility patterns of aerobic and facultative Gram-negative bacilli causing intra-abdominal infections: results from the SMART studies, 2003–2007

M. Guembe, E. Cercenado, M. Marin, R. Insa, E. Bouza (Madrid, ES)

Objective: SMART (Study for Monitoring Antimicrobial Resistance Trends) is an ongoing global antimicrobial surveillance programme focused on clinical isolates from intra-abdominal infections (IAI). The objective of this subanalysis was to assess the evolution of the antimicrobial susceptibility patterns among aerobic and facultative Gram-negative bacilli recovered over a period of 5 years at our participating institution.
Methods: We tested the in vitro activity of 10 antimicrobials, commonly used to treat IAI, against consecutive unique isolates from IAI using microdilution techniques according to the CLSI guidelines for MIC testing. All isolates were screened phenotypically for extended-spectrum β-lactamase (ESBL) production. Isolates recovered within 48 hours of hospitalisation were considered community-acquired (CA).
Results: Over the study period a total of 572 aerobic and facultative Gram-negative bacilli were recovered from 510 patients, of which 258 (45%) were CA. Enterobacteriaceae composed 91% of the total isolates. *E. coli* was the most common isolated species (52%). The susceptibility rates of Enterobacteriaceae over the study period ranged from 76.8–85.2% to the fluoroquinolones, 86.6–96.1% to cefotaxime, 91.1–100% to cefepime, 89–96.1% to piperacillin–tazobactam, 95.5–100% to amikacin, 98.2–100% to imipenem, and 98.2–100% to ertapenem. ESBLs were detected in 6.3% of *E. coli*, 5.4% of *Klebsiella* spp., and 2.7% of *Enterobacter* spp. ESBL producers generally had a more antibiotic-resistant profile than non-ESBL producers and 16% of them were CA. Susceptibility rates to fluoroquinolones, cefepime, piperacilin-tazobactam, amikacin, imipenem, and ertapenem were, respectively, for *P. aeruginosa*: 71.8%, 76.9%, 82%, 82%, 58.9%, and 28.2%; for *A. baumannii*: 66.6%, 66.6%, 66.6%, 66.6%, 100%, and 33.3%; and for *S. maltophilia*: 42.9%, 0%, 0%, 14.3%, 0%, and 0%.
Conclusions: Over the 5-year-study period we have not observed significant increases in resistance of aerobic and facultative Gram-negative bacilli causing IAI to commonly used β-lactam antimicrobial drugs. A minority of ESBL-producing Enterobacteriaceae were CA. The carbapenems, including group I agents like ertapenem, were the most reliably active drugs in vitro against isolates producing IAI.

P671 **Sentinel Surveillance of Antibiotic Resistance in Switzerland (SEARCH)**

A. Kronenberg, K. Mühlemann, M. Schlegel, J. Evison on behalf of the Sentinel Surveillance of Antibiotic Resistance in Switzerland (SEARCH)

Objectives: Comprehensive, representative and valid surveillance of antibiotic resistance on local, national and international levels is key to resistance control. We established a national surveillance programme in Switzerland within the frame of the National Research Program of Antibiotic Resistance (NRP49).

Methods: Routine resistance data are collected electronically on a weekly base from 22 clinical microbiology laboratories into a central data base. Data are validated, mapped to a common nomenclature and subjected to algorithms identifying double samples, defining microorganisms as contaminants versus pathogens and nosocomial versus community-acquired.

Results: In 2006 SEARCH received resistance data on 100,988 clinical isolates and 396 different bacterial species. The system represents approximately 80% of acute care hospital days and >30% of Swiss practitioners in the outpatient setting. Geographical distribution is even. 12.2% of samples derive from children <15 years of age and 4.6% from <2 years olds.

Isolates from sterile anatomical sites contribute 24% of all data. The relative distribution of hospital isolates was 24.6% from outpatient departments, 17.2% from surgery, 16.6% from internal medicine, 8.1% from intensive care units, 5.5% from paediatrics, 4.4% from obstetrics and gynaecology and 23.6% mixed or others. Among practitioners providing isolates the specialities were 30.4% general practitioners, 20.2% gynaecologists, 14.9% internal medicine, 7.6% paediatricians and 26.9% others.

In 2006, 2305 Swiss hospitalised patients experienced colonisation or infection by at least on of four prominent multi-resistant germs (MDR) (Meticillin-resistant *S. aureus*, extended-spectrum β-lactamase producers, multi-resistant *P. aeruginosa* and *Acinetobacter* spp.) and 15.2% of these had invasive infection. Attributable mortality was at least 80 deaths per year. Prevalence of MDR showed significant geographical differences with higher rates in South-West Switzerland (6.6%) compared to the Northeast (3.8%, $p < 0.001$).

Conclusion: The Swiss national system for antibiotic resistance surveillance provides a valuable tool for large scale, detailed and timely monitoring of antibiotic resistance in human medicine.

P672 **Antimicrobial susceptibility patterns of inducible Enterobacteriaceae isolated from intra-abdominal infections worldwide: results from SMART 2006**

F. Baquero, F. Rossi, P. Hsueh, D. Paterson, G. Bochicchio, G. Gallagher, K. Lantz, J. Baez-Villasenor, J. Chow (Madrid, ES; Sao Paulo, BR; Taipei, TW; Pittsburgh, Baltimore, West Point, US)

Objective: SMART (Study for Monitoring Antimicrobial Resistance Trends) is an ongoing global antimicrobial surveillance programme focused on clinical isolates from intra-abdominal infections (IAI). We assessed antimicrobial susceptibility patterns among inducible Enterobacteriaceae worldwide in 2006.

Methods: 82 worldwide sites (distributed as: Asia/Pacific – 24; Europe – 34; Latin America – 11; Middle East/Africa – 5; North America – 8) tested the in vitro activity of 12 antimicrobial agents commonly used to treat IAI against consecutive unique inducible Enterobacteriaceae isolated from IAI. Microdilution techniques followed Clinical Laboratory Standard Institute (CLSI) guidelines. All *Enterobacter*, *Serratia*, *Citrobacter*, *Providencia* spp., *Morganella morganii*, *Hafnia alvei*, & *Proteus vulgaris* were considered for the purposes of this study to possess an inducible ampC β-lactamase gene.

Results: Inducible Enterobacteriaceae were recovered from 19% (1175/6134) pts, representing 18% (1204/6633) of total isolates. 38% (461) of isolates were recovered <48 hrs and 60% (721) were recovered ⩾48 hrs of hospitalisation; whereas, for 2% (22) the time recovered was unknown. *Enterobacter* spp. (48%), *Citrobacter* spp. (24%), *M. morganii* (11%), and *Serratia* spp. (7%) were the most common inducible Enterobacteriaceae. % susceptibility rates are reported below.

Conclusion: *Enterobacter* species were the most common isolates. Ampicillin-sulbactam and cefoxitin were the least active agents against inducible Enterobacteriaceae; whereas, imipenem, ertapenem, and amikacin were the most active agents in vitro.

	Enterobacter spp. N = 583	*Citrobacter freundii* N = 210	*Morganella morganii* N = 127	*Serratia* spp. N = 86
Ertapenem	93	98	99	99
Imipenem	98	98	98	99
Cefepime	85	91	97	94
Ceftriaxone	60	64	80	87
Cefoxitin	8	13	78	38
Ceftazidime	61	66	77	91
Cefotaxime	61	62	91	86
Ampicillin–sulbactam	21	43	4	13
Piperacillin–tazobactam	75	80	95	91
Amikacin	94	92	98	99
Ciprofloxacin	84	80	86	87
Levofloxacin	88	85	89	94

P673 **CARE-ICU – Controlling Antibiotic REsistance in Intensive Care Units – First report from a web-based programme for improved infection control in European ICUs**

H. Hanberger, D. Arman, H. Gill, S. Kalenic, P. Naaber, E. Scicluna, C. Suetens on behalf of CareICU – IPSE

Background: CARE-ICU is a web-based programme for IC surveillance in the ICU setting developed within the EU Commission sponsored project IPSE. The aim of the programme is to improve surveillance and control of antibiotic resistance (ABR), AB consumption (ABC) and hygienic precautions in the ICU setting of EU member states.

Methods: A programme for yearly registration of ABC, resistance and clinical practices with automatic feedback through a website http://www4.smittskyddsinstitutet.se/careicu was developed. Participants are national ICU networks and individual ICUs. The national contact points of IPSE were asked to identify ICUs who would be willing to take part in the large pilot study. ABR was defined as the sum of intermediate susceptible and resistant strains. Antibiotics (AB) to which >90% of isolates of a species were susceptible were defined as treatment alternatives (TA90) which is a novel index of susceptibility to measure the magnitude of MDR among Gram-negative bacteria. For each ICU the clinical practices and infection control measures were analysed in relation to the needs based on local resistance patterns and ABC.

Results: 34 ICUs in 8 countries participated in the collection of ICU data for 2005. ABC varied widely from 348–4992 DDD1000 (defined daily dosages per 1000 occupied bed days), median 1417 DDD1000. Frequencies of ABR varied greatly between species, ICUs and countries: The median (range) of MRSA, ESBL phenotype of *E. coli*, ESBL phenotype of *K. pneumoniae* were in percentages: 11.6 (0–100), 3.9 (0–80) and 14.3 (0–77.8) respectively. TA90 for *P. aeruginosa* to aminoglycoside, ceftazidime, ciprofloxacin and carbapenem varied between 0 (9 ICUs), 1 (8 ICUs), 2 (3 ICUs), 3 (6 ICUs) and 4 (4 ICUs). Failure to screen for alert microorganisms in relevant patients at admission was a general problem as well as lack of rooms for isolation precautions and cohort care for patients colonised or infected with Alert organism. Understaffing was common but facilities for hand disinfection was in general available by each bed.

Conclusions: CARE-ICU has become a focal point for promoting more appropriate use of AB and improved infection control. By correlating ABC and resistance, as well as hygienic precautions, best practice in AB policy and hygiene interventions was defined for each unit. The single most needed improvement in almost all settings was increased hygiene compliance of healthcare workers.

P674 Antimicrobial susceptibility of the bacteria causing community-acquired respiratory tract infections in Poland, 2005–2006 (continuation of the Alexander Project)

M. Kadlubowski, A. Skoczynska, A. Klarowicz, W. Hryniewicz (Warsaw, PL)

Objectives: The aim of the study was to evaluate susceptibility patterns of major agents of acute pharyngitis/tonsilitis and lower respiratory tract infections in Poland, 2005–2006.

Methods: The study was performed on 811 isolates of the four species: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Streptococcus pyogenes* and *Moraxella catarrhalis*. The strains were isolated in 42 healthcare centres, from ambulatory or hospitalised patients. In the second case, the study included only the isolates, which were recovered during the first 48 hours after the patients' admission. Isolates were checked for their susceptibility to drugs commonly used in the treatment of respiratory tract infections, according to the CLSI guidelines. ATCC strains were used for the quality control purposes.

Results: Among pneumococci, more than 20% were non-susceptible to penicillin (PNSP), almost 70% of which were fully resistant. Nearly 90% of PNSP were also resistant to at least two other drug groups, e.g. macrolides and co-trimoxazole. Almost 10% of pneumococci were non-susceptible to the 3rd-generation cephalosporins. Beside penicillin, the lowest in vitro activity against *S. pneumoniae* had co-trimoxazole and tetracycline. Among *H. influenzae*, 8.1% were ampicillin-resistant β-lactamase producers. All of them were in vitro susceptible to amoxicillin/clavulanic acid and 3rd-generation cephalosporins. Co-trimoxazole and clarithromycin were the least active in vitro drugs against this species. More than 91% of *M. catarrhalis* isolates were penicillin-resistant β-lactamase producers, although all of them were susceptible to various other antimicrobials. All of the group A streptococci were susceptible to penicillin, however an increase in resistance to tetracycline and macrolides was observed.

Conclusion: Although the frequency of PNSP (~20%) seems to be stable in Poland, the number of isolates resistant to at least three groups of antimicrobials is being increased. Enzymatic resistance of *H. influenzae* to β-lactams is stable as well (~10%) of isolates, but resistance to macrolides is growing. Further increase in resistance of *S. pyogenes* to all groups of macrolides is being observed. *M. catarrhalis* remains susceptible to many antibiotics.

P675 Comparison of antimicrobial susceptibilities of bacteria isolated in Canada, the United States, and Mexico – Results from the T.E.S.T. Program 2004–2007

R. Badal, S. Bouchillon, B. Johnson, M. Hackel, J. Johnson, D. Hoban, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: The Tigecycline Evaluation Surveillance Trial (T.E.S.T.) is a longitudinal surveillance study that monitors the in vitro activity of tigecycline (TIG) and several comparator antimicrobics in dozens of countries. This analysis of T.E.S.T. data compares the susceptibility of commonly-isolated pathogens collected in Canada, The United States of America, and Mexico.

Methods: 49,886 isolates were collected and identified to the species level at 231 participating sites (215 in the USA, 8 in Canada, and 8 in Mexico) and confirmed by the central laboratory. MICs were determined by each site using supplied broth microdilution panels and interpreted according to CLSI guidelines. % susceptible of each species or phenotype to each of the study drugs was determined for isolates from each of the 3 countries.

Results: Organism/antimicrobic combinations which showed more than 25% variation in % susceptible between countries are listed below:

Organism	Canada	USA	Mexico
Acinetobacter	n = 123	n = 3113	n = 95
Ak	91	83	56
Cpe	79	50	54
Caz	81	50	28
Lvx	81	52	35
PT	86	60	40
S. pneumoniae	n = 31	n = 1070	n = 70
Mer	94	79	66
H. influenzae	n = 132	n = 2749	n = 67
Amp	83	73	57
E. coli	n = 220	n = 6370	n = 238
Aug	76	76	37
Amp	47	43	8
Cpe	96	98	62
Cax	95	95	48
Lvx	77	75	29
Min	85	87	62
ESBL+	n = 16	n = 595	n = 126
Mer	100	73	99
PT	94	52	79

Ak = Amikacin; Cpe = cefepime; Caz = ceftazidime; Lvx = levofloxacin; PT = piperacillin/tazobactam; Mer = meropenem; Amp = ampicillin; Aug = amox/clav; Cax = ceftriaxone; Min = minocycline.

Conclusions: There are several pathogens for which antibiograms differ dramatically between Canada, the USA, and Mexico. Although the US sample size is vastly larger than the other two countries, there were enough strains to lend credence to the data from Canada and Mexico. Many drugs showed no significant difference in %S among the three countries, but when there were large variations, Mexico usually had the lowest susceptibility rates, and Canada the highest. Interestingly, the positions of Mexico and the USA were reversed for ESBL producers vs. Mer and PT.

P676 A global perspective of antimicrobial in vitro activity from the T.E.S.T. Program: annual analysis from 2004–2006

S. Bouchillon, B. Johnson, M. Hackel, J. Johnson, D. Hoban, R. Badal, M. Dowzicky (Schaumburg, Collegeville, US)

Background: Tigecycline, the first member of the glycylcyclines, was marketed in mid 2005 and has demonstrated success against multiply-resistant species and phenotypes. Due to its chemical structure, resistance to tigecycline is reportedly difficult to produce even in the laboratory. The T.E.S.T. Program is an ongoing global surveillance with the first post-marketing prospective report of tigecycline and comparator in vitro activity for the years 2004 through 2006.

Methods: More than 60,000 clinical isolates were collected from 335 investigative sites in 47 countries worldwide. MICs were determined by broth microdilution according to CLSI guidelines using identical panels.

Results: Results are given by year for all pathogens and antimicrobials. Summary data for tigecycline and key species are presented in the table.

Conclusions: Tigecycline demonstrated no significant shift in MIC values over three years from its pre-marketing baseline values. Tigecycline activity was retained even against strains resistant to other antimicrobials, including ESBL-producers, *Acinetobacter* spp., meticillin-resistant *S. aureus*, vancomycin-resistant enterococci, and *S. pneumoniae*.

Organism	n (04/05/06)	2004		2005		2006

P677 Prevalence of *Helicobacter pylori* resistance to antimicrobial agents at two different locations in Belgium: a 10-year surveillance

Y. Glupczynski, H. Nizet, C. Berhin, C. Baude (Yvoir, BE)

Objectives: Monitoring of primary antibiotic resistance in *H. pylori* at a local level is of utmost importance since antimicrobial resistance is an important indicator of treatment failures. We aimed to compare the rates of primary antimicrobial resistance of *H. pylori* (Hp) at two locations in Belgium and to investigate possible links with disease severity, gender, age and ethnicity of patients (pts.).

Methods: Between 01/98 and 10/07, Hp culture of gastric biopsies from untreated pts. endoscoped at UCL St-Luc, Brussels (Br) and at UCL Mont-Godinne, Yvoir (Yv), south Belgium was carried out centrally at one laboratory. Susceptibility testing (disc diffusion and/or Etest) to the following agents was performed: metronidazole (Mtz), clarithromycin (Cla), amoxicillin (Amx), levofloxacin (Lvx) and tetracycline (Tet).

Results: Data were available for 1614 Hp isolates (977 in Brussels; 637 in Yvoir). The prevalence of Hp infection was 25% in B (36% non-caucasians) and 21% in Y (9% non Caucasians). Global primary resistance rates were 31.7% to Mtz; 18.4% to Cla and 16.8% to Lvx; 7.4% of the strains displayed double Mtz/Cla resistance and 2.9% displayed triple resistance (Mtz/Cla/Lvx). Resistance rate to Amox and Tet was T1%. The rate of Mtz resistance was higher in B than in Y (40% vs. 25%; $P < 0.05$) while it was identical for Cla (16.6% vs. 21.2%, NS) and for Lvx (15.5 vs. 19.0%; NS). Primary resistance to Mtz was significantly higher in non-Belgian born patients (41.1% vs. 27.8% in Belgian-born; $P < 0.01$) and in females (38.2% vs. 26.1% in males; $P < 0.05$). There was no difference in resistance between ulcer and non-ulcer dyspepsia-associated Hp isolates.

Conclusion: High Mtz, Cla and Lvx resistance rates were observed at two different locations in Belgium and no significant trends occurred over time, except for Lvx resistance which increases from 10% in 2002 to over 25% in 2007. Country of birth and female gender were the only risk factors identified for Mtz resistance. Our results emphasize the importance of local data for optimisation of anti-Hp treatment strategies.

P678 Potency and spectrum of tigecycline tested against bacterial pathogens producing skin and skin structure infections in European medical centres, including community-acquired meticillin-resistant *S. aureus*

H. Sader, R. Jones, G. Moet, T. Fritsche (North Liberty, US)

Objective: To evaluate the activity and potency of tigecycline when tested against a large collection of bacterial pathogens causing skin and skin structure infections (SSSI). Tigecycline is the sentinel representative of the glycylcycline class and was recently approved by the European Medicines Agency for the treatment of complicated SSSI and intra-abdominal infections.

Methods: Consecutive, non-duplicate bacterial isolates (4,567 strains) were collected from 2000 to 2007 from patients with documented SSSI in >30 medical centres (14 countries) participating in the Tigecycline Surveillance Program in Europe. All isolates were tested using CLSI broth microdilution methods against tigecycline and key comparator agents commonly used for therapy of SSSI. Tigecycline-susceptible (S) breakpoints (US-FDA/EUCAST) were defined as ⩽2/⩽1 mg/L for Enterobacteriaceae (ENT); ⩽0.5/⩽0.5 mg/L for staphylococci, and ⩽0.25/⩽0.25 mg/L for streptococci and enterococci. *S. aureus* infections diagnosed within the first 48 hours of hospitalisation were considered to be of community origin.

Results: SSSI pathogen rank order (top 8), potency (MIC90) and S rates for tigecycline are shown in the Table. *S. aureus* (22.7% MRSA) was isolated from 45.7% of SSSI cases and tigecycline inhibited 99.8% of strains, including all community-acquired (CA)-MRSA, at the S breakpoint. CA-MRSA showed low S to erythromycin (37.5%), clindamycin (63.5%) and levofloxacin (17.5%). Tigecycline was also very active against enterococci (93.2% S), including vancomycin-non-S strains (100.0% S), BHS (99.6% S) and CoNS (97.9% S). Linezolid was also active against Gram-positive organisms, but generally 8-fold less potent than tigecycline. Tigecycline (98.4–100.0% S) and imipenem (98.4–100.0% S) were the most active compounds tested against *E. coli*, *Klebsiella* spp. and *Enterobacter* spp., while high rates of R to levofloxacin (5.5–16.4%) and gentamicin (7.1–12.7%) were observed among these pathogens.

Organism (no. of isolates/% of total)	MIC_{90}/%S[a]				
	TIG	LEV	CLI	T/S	LZD
S. aureus (2,089/45.7)	0.25/99.8	>4/76.4	>2/88.5	⩽0.5/97.6	2/100.0
Meticillin-resistant *S. aureus* (MRSA; 474/10.4)	0.25/99.6	>4/11.0	>2/59.1	2/91.7	2/100.0
Community-acquired (CA)-MRSA (137/6.6)	0.25/100.0	>4/17.5	>2/63.5	1/94.9	2/100.0
E. coli (426/9.3)	0.25/99.5	>4/80.3	–/–	>2/70.1	–/–
P. aeruginosa (PSA; 399/8.7)	>4/–	>4/71.4	–/–	>2/6.3	–/–
Enterococci (293/6.4)	0.25/93.2	>4/59.0	–/–	–/–	2/100.0
Beta-haemolytic streptococci (BHS; 256/5.6)	⩽0.12/100.0	1/100.0	⩽0.25/92.6	⩽0.5/99.6	1/100.0
Coagulase-neg. staphylococci (CoNS; 234/5.1)	0.5/97.9	>4/49.6	>2/74.4	>2/69.3	1/100.0
Enterobacter spp. (ESP; 182/4.0)	1/98.4	1/92.3	–/–	>2/89.6	–/–
Klebsiella spp. (KSP; 142/3.1)	1/100.0	4/88.0	–/–	>2/81.0	–/–

a. According to US-FDA breakpoints. TIG = tigecycline; LEV = levofloxacin; CLI = clindamycin; T/S = trimethoprim/sulfamethoxazole and LZD = linezolid.

Conclusions: Tigecycline was highly active against the top 8-ranked pathogens producing SSSI, except for *P. aeruginosa*, and showed the broadest spectrum of activity among the antimicrobials tested. Tigecycline, linezolid and vancomycin were the most active compounds tested against Gram-positive species while tigecycline, amikacin and imipenem were the most active against Gram-negatives. Tigecycline represents a welcome choice for use in treating common Gram-positive and negative pathogens producing serious SSSI.

P679 Trends in bacteraemia: England 2002–2006

N. Potz, M. Lillie, J. Davies, C. Jackson, A. Pearson (London, UK)

Objectives: This paper presents the nine species of bacteria (and *Candida*) responsible for the majority of bloodstream infections (BSI) in England during 2006, and the changes in trends of these species over the last five years.

Methods: Voluntary reports of bacteraemia are collected using electronic reporting from laboratories in England and Wales to a national database. Information indicating how many blood cultures were taken and how many tested positive were provided through the mandatory MRSA surveillance undertaken in England. Bloodstream infections are defined as clinically-significant positive blood cultures.

Results: The total number of blood cultures taken has increased by over 17% between 2002 and 2006, while the number of cultures that prove positive has increased by 14%. The numbers of bloodstream infections reported has increased, however, this may in part be due to an increase in voluntary reporting. The top five organisms responsible for BSI have changed in relative frequency over the last five years, with *E. coli*

overtaking *S. aureus* rather dramatically as the most common cause of bacteraemia.

	2002	2003	2004	2005	2006
Total blood cultures	1500832	1611714	1546630	1695371	1752914
Total positive blood cultures	249311	264766	261899	278281	285152
All episodes of bloodstream infections	76231	92770	96101	102785	109696
	No. (%)	No. (%)	No. (%)	No. (%)	No. (%)
Escherichia coli	12709 (16.7)	15052 (16.2)	15741 (16.4)	16961 (16.5)	18043 (16.4)
Coagulase negative staphylococci	6604 (8.7)	8609 (9.3)	10091 (10.5)	11708 (11.4)	14184 (12.9)
Staphylococcus aureus	12895 (16.9)	14603 (15.7)	14173 (14.7)	14065 (13.7)	13616 (12.4)
Enterococcus spp.	4421 (5.8)	5611 (6.0)	5887 (6.1)	6477 (6.3)	7070 (6.4)
Klebsiella spp.	3515 (4.6)	4169 (4.5)	4639 (4.8)	4853 (4.7)	5162 (4.7)
Streptococcus pneumoniae	4163 (5.5)	5135 (5.5)	4526 (4.7)	4971 (4.8)	4539 (4.1)
Pseudomonas spp.	2382 (3.1)	2969 (3.2)	2897 (3.0)	3069 (3.0)	3454 (3.1)
Enterobacter spp.	1874 (2.5)	2256 (2.4)	2284 (2.4)	2314 (2.3)	2410 (2.2)
Proteus spp.	1662 (2.2)	1882 (2.0)	1818 (1.9)	1805 (1.8)	1839 (1.7)
Candida spp.	1042 (1.4)	1272 (1.4)	1376 (1.4)	1573 (1.5)	1687 (1.5)

Conclusions: The increase in blood culture reports is thought to be due to an increased number of rapid investigations of pyrexia of unknown origin (PUO) in patients presenting in the Accident & Emergency Department. Whilst the numbers of *E. coli* bacteraemia reports have increased, their proportion of all BSIs has remained stable. It is therefore unclear how many of the increased number of reports represent a true increase in case numbers and how many represent an increase in case reporting. The apparent increase in the proportions of coagulase-negative staphylococci requires further investigation. It is interesting to observe that no apparent increase in the proportion of candidaemia BSI was seen as has been reported in other countries where there are an increasing proportion of elderly and immunocompromised patients.

P680 In vitro activity of tigecycline tested against pneumonia pathogens from patients hospitalised in European medical centres, including multidrug-resistant *Acinetobacter* spp.

H. Sader, R. Jones, M. Janechek, T. Fritsche (North Liberty, US)

Objectives: Emergence of resistance (R) among pneumonia-producing pathogens has been a variable that confounds empiric management. We evaluated the activity of tigecycline against leading bacterial pathogens recovered from patients hospitalised with pneumonia. Tigecycline was approved by the European Medicines Agency and US-FDA for the treatment of complicated skin and skin structure infections and intra-abdominal infections and is currently under investigation for treatment of hospital acquired pneumonia.

Methods: Consecutive, non-duplicate, lower respiratory tract isolates (3,864) were submitted from 34 medical centres located in Europe (13 countries) and Israel in the 2000–2007 period. Susceptibility (S) tests were performed using CLSI methods (including ESBL confirmatory tests) and interpreted by US-FDA and EUCAST criteria.

Results: Ranking of the top-10 occurring pneumonia pathogens and key resistance (R) characteristics were (see Table): *S. aureus* (28.3% oxacillin-R [MRSA]) > *P. aeruginosa* (19.6 imipenem [IMI]-R) > *E. coli* (8.5% ESBL) > *Klebsiella* spp. (28.9% ESBL) > *Enterobacter* spp. (25.6% ceftazidime [CAZ]-R) > *Acinetobacter* spp. > *S. pneumoniae* (23.1% penicillin-R) > *Serratia* spp. > *S. maltophilia* > *H. influenzae* (12.8% β-lactamase positive). *Acinetobacter* spp. exhibited high R rates to IMI (43.1%), CAZ (77.0%), ciprofloxacin (CIP; 82.8%) and amikacin (AMK; 65.1%); while 34.9% of strains were R to all 4 drugs (MDR). R to these antimicrobials did not adversely affect tigecycline activity, which inhibited >95% of strains non-S to CAZ, CIP or AMK, 93.3% of strains non-S to IMI and 91.8% of MDR strains at ⩽2 mg/L. Tigecycline was also very active against *S. maltophilia* (MIC90, 2 mg/L; 99.2% inhibited at ⩽2 mg/L), MRSA (MIC90, 0.25 mg/L; 99.5% S) and Enterobacteriaceae with an ESBL-phenotype, but showed limited activity against PSA.

Conclusions: Tigecycline is a potent agent targeting pneumonia pathogens displaying highly resistant phenotypes including *S. aureus*, Enterobacteriaceae, *S. pneumoniae*, *H. influenzae*, and some non-fermentative Gram-negative bacilli. Only tigecycline and the polymyxins showed reasonable in vitro activity against *Acinetobacter* spp. Empiric use of tigecycline may be prudent for patients less likely to have *P. aeruginosa* as a causative pathogen or for directed therapy of indicated species.

Organism (no. tested/% of total)	Tigecycline MIC (mg/L)			% S
	50%	90%	Range	(US-FDA/ EUCAST)
S. aureus (1,067/27.6)	⩽0.12	0.5	⩽0.12–1	99.8/99.8

a. Enterobacteriaceae breakpoints were used for comparison purposes only.

P681 In vitro activity of tigecycline against inpatient and outpatient isolates from a European population

M. Hackel, S. Bouchillon, B. Johnson, R. Badal, J. Johnson, D. Hoban, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: Tigecycline, a member of a new class of antimicrobials (glycylcyclines), has been shown to have potent broad spectrum activity against most commonly encountered species responsible for community and hospital acquired infections. The T.E.S.T. Program surveyed the in vitro activity of tigecycline and comparator compounds against in-patient and out-patient pathogens from Europe for the period from 2004 to 2007.

Methods: A total of 16,451 clinical isolates from 93 testing sites in 22 European countries were tested. Minimum Inhibitory Concentration (MICs) were determined by each site using common broth microdilution panels and interpreted according to EUCAST guidelines.

Results: See the tables.

	Enterobacteriaceae				*Acinetobacter* spp.			
	In-patients (n = 5,546)		Out-patients (n = 1,097)		In-patients (n = 926)		Out-patients (n = 148)	
	%S	MIC_{90}	%S	MIC_{90}	%S	MIC_{90}	%S	MIC_{90}

na = Breakpoints not available.

	S. aureus				*Enterococcus* spp.			
	In-patients (n = 1,415)		Out-patients (n = 374)		In-patients (n = 1,042)		Out-patients (n = 119)	
	%S	MIC_{90}	%S	MIC_{90}	%S	MIC_{90}	%S	MIC_{90}
Tigecycline	100	0.25	100	0.25	100	0.12	100	0.12
Levofloxacin	72.6	16	83.9	8	54.1	>32	69.3	>32
Linezolid	100	4	100	4	100	2	100	2
Minocycline	99	0.5	99	0.5	53.2	>8	41.6	>8
Vancomycin	100	1	100	1	93.9	2	95	2

Conclusion: Tigecycline's in vitro activity was comparable to or greater than most commonly prescribed broad spectrum antimicrobials without any demonstrable change in activity between in-patient and

out-patient bacterial study strains. Tigecycline's inhibitory activity against Enterobacteriaceae, and *Acinetobacter* spp. was comparable to imipenem. Against Gram-positive organisms, tigecycline's activity was comparable to linezolid and vancomycin.

P682 Comparative analysis of tigecycline in South America from 2004–2007

M. Hackel, R. Badal, S. Bouchillon, B. Johnson, J. Johnson, D. Hoban, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: Tigecycline, the first member of the glycylcyclines, was first marketed in 2005 and has demonstrated success against multiple-resistant species and phenotypes. The T.E.S.T. Program is an ongoing global surveillance with the first post-marketing prospective report of tigecycline and comparator in vitro activity for the years 2004 through 2007.
Methods: 4,230 clinical isolates were collected from 16 investigative sites in 5 countries in South America. MICs were determined by broth microdilution according to CLSI guidelines using identical panels.
Results: Results are given by year for pathogens and antimicrobials. Summary data for tigecycline and key species are listed in the table.

Organism	N(04/05/06/07)	2004		2005		2006		2007	
		MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}
Enterobacteriaceae	234/585/512/260	0.5	1	0.5	1	0.5	1	0.5	1
ESBL producers[a]	25/103/73/26	0.5	2	0.5	2	0.5	1	0.5	1
Acinetobacter spp.	53/111/59/50	0.5	1	0.5	1	0.5	1	0.5	1
P. aeruginosa	55/130/144/62	8	>16	8	16	8	>16	8	>16
S. aureus	64/215/116/97	0.06	0.12	0.12	0.25	0.12	0.25	0.12	0.25
MRSA	28/94/62/51	0.12	0.25	0.12	0.25	0.12	0.25	0.12	0.25
Enterococcus spp.	37/93/88/42	0.06	0.12	0.12	0.25	0.06	0.12	0.06	0.12
S. pneumoniae	41/96/57/52	0.25	0.5	0.12	0.5	0.015	0.06	0.015	0.06
H. influenzae	29/107/20/23	0.5	0.5	0.25	0.5	0.12	0.25	0.12	0.25

Conclusions: Other than a 1-doubling dilution increase in the MIC90 of *S. aureus*, tigecycline demonstrated no increase in MIC50/90 values over four years from its pre-marketing baseline values. Tigecycline's activity was retained even against strains resistant to other antimicrobials, including ESBL-producers, *Acinetobacter* spp., meticillin-resistant *S. aureus*, vancomycin-resistant enterococci, and penicillin-resistant *S. pneumoniae*.

P683 Tigecycline activity in Europe: a comparative analysis by country 2007

M. Hackel, R. Badal, S. Bouchillon, J. Johnson, D. Hoban, B. Johnson, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: Development of bacterial resistance continues to cause concern world wide, but the availability of newer agents offers clinicians options for therapy. Tigecycline has a very broad spectrum of activity, including strains resistant to other drugs. As part of the global Tigecycline Evaluation Surveillance Trial (TEST), strains collected in 22 European countries in 2007 were evaluated for susceptibility to several commonly used antimicrobials.
Methods: 14,254 strains were collected and identified at 93 sites in 22 countries. MICs were determined at each site using EUCAST guidelines on microdilution panels.
Results: The table summarizes tigecycline results.
Conclusions: Bacteria isolated from than 22 different European countries had generally similar antibiograms, with no isolates from any site showing significantly different sensitivity patterns. The greatest variability was seen in *Acinetobacter*, with TIG MIC50 values ranging from 0.06 to 1 μg/mL. TIG's consistant broad spectrum of activity may make it an excellent therapeutic option against European pathogens.

P684 In vitro activity of tigecycline and 13 comparators against pathogens from a global population of intensive care patients in 2007

M. Hackel, D. Hoban, S. Bouchillon, B. Johnson, R. Badal, J. Johnson, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: Tigecycline is a novel antimicrobial from a new class of compounds, the glycylcyclines, which has been shown to have potent broad spectrum activity against most commonly encountered species responsible for community and hospital acquired infections. The Tigecycline Evaluation Surveillance Trial (TEST), a global longitudinal surveillance study, surveyed the in vitro activity of tigecycline and 13 comparator compounds against pathogens from ICU patients from a global population during 2007.
Methods: A total of 14,113 clinical isolates from 386 testing sites in 49 countries were evaluated. Minimum Inhibitory Concentration (MICs) were determined by each site using common broth microdilution panels and interpreted according to CLSI and FDA guidelines.
Results: See the tables.

Drug	Enterobacteriaceae (n = 7,576)		*Acinetobacter* spp. (n = 1,646)	
	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}
Tigecycline	0.5	2	0.5	1
Amikacin	2	4	8	>64
Cefepime	⩽0.5	8	16	>32
Imipenem	0.5	1	1	>16
Levofloxacin	0.06	8	4	>8
Minocycline	2	16	⩽0.5	8
PipTazo	2	128	64	>128

Drug	*S. aureus* (n = 1,722)		*Enterococcus* spp. (n = 1,252)	
	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}
Tigecycline	0.12	0.25	0.06	0.12
Levofloxacin	0.25	32	16	>32
Linezolid	2	2	2	2
Minocycline	⩽0.25	0.5	4	>8
Vancomycin	1	1	1	>32

Conclusion: Tigecycline's in vitro activity was comparable to or greater than most commonly prescribed broad spectrum antimicrobials for all ICU bacterial study strains encountered. Tigecycline's inhibitory activity against Enterobacteriaceae, and *Acinetobacter* spp. was comparable to imipenem. Against Gram-positive organisms, tigecycline's MIC90 values of ⩽0.25 μg/mL suggest that tigecycline may be an effective and reliable therapeutic option against these pathogens in an Intensive Care setting.

P685 Tigecycline activity tested against bacterial isolates causing bloodstream infections in European medical centres

H. Sader, G. Moet, T. Fritsche, R. Jones (North Liberty, US)

Objective: To assess the activity of tigecycline against bloodstream infection (BSI) isolates from European hospitals. Tigecycline is a novel glycylcycline antimicrobial approved by the European Medicines Agency for the treatment of complicated skin and skin structure infections and intra-abdominal infections.

Methods: Bacterial isolates (non-duplicates) were consecutively collected in the 2000–2007 period from documented BSI in patients hospitalised in 34 medical centres located in Europe (13 countries) and Israel. Frequency of occurrence of pathogens was determined and their antibiograms assessed using reference broth microdilution methods according to CLSI M7-A7 (2006). Tigecycline-susceptible (S) breakpoints (US-FDA/EUCAST) were defined as ⩽2/⩽1 mg/L for Enterobacteriaceae (ENT); ⩽0.5/⩽0.5 mg/L for staphylococci, and ⩽0.25/⩽0.25 mg/L for streptococci and enterococci.

Results: A total of 25,401 strains were tested. Tigecycline was highly active against the 10 most frequent pathogens (Table), except for *P. aeruginosa* (PSA). Among the 5 most common pathogens (18,802 strains; 74% of the total), tigecycline was active against >99% at the established S breakpoints. The main resistance phenotypes detected were meticillin-resistant (R) *S. aureus* (MRSA; 28.3%) and CoNS (77.6%), ciprofloxacin-R *E. coli* (20.3%), extended-spectrum β-lactamase (ESBL)-screen-positive *Klebsiella* spp. (22.8%) and *E. coli* (7.9%), imipenem-R PSA (IRPSA; 21.7%) and *Acinetobacter* spp. (ASP; 30.5%), and vancomycin-R enterococci (VRE; 5.0%). Tigecycline activity against MRSA (MIC90, 0.25 mg/L; 99.8% S) was similar to that against meticillin-S *S. aureus* (MIC90, 0.25 mg/L; 99.9% S), and 98.0% of VRE were S to tigecycline. ESBL-producing *E. coli* and KSP exhibited high rates of R to levofloxacin (62.4 and 31.8%, respectively) and gentamicin (31.7 and 45.1%), but were S to tigecycline (100.0 and 98.9%, by US-FDA breakpoints). 95.3% of ceftazidime-R ESP and 96.1% of imipenem-R ASP were inhibited at ⩽ 2 mg/L of tigecycline.

Organism (no. tested/% of total)	Cumulative % inhibited at tigecycline MIC (mg/L) of:						% S
	⩽0.12	0.25	0.5	1	2	4	(US-FDA/ EUCAST)
E. coli (5,793/22.8)	66.5	95.7	99.6	99.9	>99.9	100.0	>99.9/99.9
S. aureus (5,642/22.6)	68.7	95.3	99.9	100.0	–	–	99.9/99.9
Coagulase-neg. staphylococci (CoNS; 3,396/13.4)	57.0	88.8	98.9	100.0	–	–	98.8/98.9
Enterococcus spp. (2,265/8.9)	75.3	97.0	99.9	100.0	–	–	97.0/97.0
Klebsiella spp. (KSP; 1,706/7.6)	8.5	58.7	87.3	96.2	99.4	>99.9	99.4/96.2

[a] ENT breakpoints were applied for comparison purposes.

Conclusions: Tigecycline exhibited a wide-spectrum of activity and potency versus contemporary BSI isolates collected in Europe, including multidrug-resistant organisms.

P686 Extended-spectrum β-lactamase production in Europe

M. Hackel, R. Badal, S. Bouchillon, J. Johnson, D. Hoban, B. Johnson, M. Dowzicky (Schaumburg, Collegeville, US)

Objectives: Infection by extended-spectrum beta lactamase (ESBL)-producing bacterial pathogens is increasing worldwide, with the prevalence of ESBLs in Europe varying greatly from country to country. Patients with infections caused by an ESBL-producing organism are at increased risk of treatment failure. The Tigecycline Evaluation Surveillance Trial (TEST), a global longitudinal surveillance study, determined the ESBL status and antibiotic susceptibilities to tigecycline and comparator compounds for 6,782 *Escherichia coli*, *Klebsiella oxytoca*, and *Klebsiella pneumoniae*, from 22 European countries from 2004 to 2007.

Methods: 6,782 Enterobacteriaceae (2,871 *E. coli*, 815 *K. oxytoca*, 1,938 *K. pneumoniae*) from 22 European countries were analysed in this survey. The isolates were identified to the species level at the participating sites and confirmed by the central laboratory. MICs were determined by each site using supplied broth microdilution panels and interpreted according to EUCAST guidelines. ESBL testing was performed by Laboratories International for Microbiology Studies (LIMS), a subsidiary of International Health Management Associates, Inc. (IHMA, Schaumburg, IL, USA) following CLSI guidelines.

Results: See the table.

	2004		2005		2006		2007	
	n (% ESBL)	TIG MIC_{90}	n (% ESBL)	TIG MIC_{90}	n (% ESBL)	TIG MIC_{90}	n (% ESBL)	TIG MIC_{90}
E. coli	558 (3.9)	0.12	525 (9.7)	0.12	994 (8.7)	0.12	794 (9.8)	0.25
ESBL	22	0.25	51	0.25	86	0.25	78	0.25
K. oxytoca	148 (5.4)	0.25	142 (2.8)	0.25	272 (2.9)	0.25	253 (2.8)	0.5
ESBL	8	0.5	4	0.5	8	0.25	7	0.5
K. pneumoniae	393 (13.0)	0.5	305 (14.4)	0.5	724 (9.7)	0.5	516 (15.5)	0.5
ESBL	51	0.5	44	0.5	70	0.5	80	0.5
Total	1099 (7.4)	0.25	972 (10.2)	0.25	3148 (5.2)	0.25	1563 (10.6)	0.25
ESBL	81	0.5	99	0.5	164	0.25	165	0.5

Conclusions: Rates of ESBL production in Europe have increased gradually during the period of 2004 to 2007, with a decrease in the year 2006. The incidence of ESBLs varies greatly from country to country, ranging from 2.6% in Denmark to 24.2% in Greece in 2007 (data not shown). Tigecycline retained excellent in vitro activity over time, with MIC90 values of ⩽0.5 μg/mL for all four years, suggesting tigecycline may be an effective option against these difficult to treat pathogens.

P687 The in vitro activity of tigecycline against 2,423 clinical isolates. Comparison of the EUCAST and the FDA approved breakpoints

J. Papaparaskevas, A. Tsakris, L. Tzouvelekis, A. Priftis, N.J. Legakis and the Hellenic Tigecycline Study Group

Objectives: The multicentre comparison of the in vitro activities of tigecycline and comparator agents against Gram-negative and Gram-positive clinical isolates.

Materials and Methods: During 2006–2007, a total of 2,423 non-duplicate clinical isolates were collected from 17 General Hospitals in Greece. MICs to tigecycline, penicillin, ampicillin, amoxicillin+clavulanic acid, piperacillin+tazobactam, cefotaxime, ceftazidime, cefepime, imipenem, amikacin, minocycline, levofloxacin, vancomycin, and linezolid were determined using a microdilution method.

Results: Species distribution included *Escherichia coli* (464, 18.8%), *Klebsiella pneumoniae* (350, 14.2%) *Enterobacter* spp. (247, 10.0%), *Acinetobacter* spp. (235, 9.5%), *Moraxella catarrhalis* (39, 1.6%), *Enterococcus* spp. (513, 20.8%), *Staphylococcus aureus* (505, 20.1%) and *Streptococcus pneumoniae* (70, 2.8%). Isolates were collected from skin and soft tissue, blood, urine, respiratory tract, intra-abdominal, iv catheter, biological fluids, and genital specimens (20.6, 18.8, 18.6, 15.2, 10.8, 3.7, 3.3, and 1.9%, respectively). Tigecycline MIC50, MIC90, as well as susceptibility rates according to FDA and EUCAST approved genus/species specific breakpoints, are shown in Table.

No significant differences were recorded between meticillin-resistant and susceptible *S. aureus*, vancomycin-resistant and susceptible *Enterococcus* spp., penicillin-resistant and susceptible *S. pneumoniae*, or imipenem-resistant and susceptible *Acinetobacter* spp.

Genus	N	MIC (mg/L)		FDA breakpoints**			EUCAST breakpoints**		
		50%	90%	S (%)	I (%)	R (%)	S (%)	I (%)	R (%)
E. coli	464	0.12	0.5	99	0.5	0.5	99	0	1
K. pneumoniae	350	0.5	1	99	0.5	0.5	91	8	1
Enterobacter spp.	247	0.5	2	93	5	2	88	6	6
ImpNS* *Enterobacteriaceae*	110	0.5	1	99	0	1	94	5	1
Acinetobacter spp.	234	1	1	No breakpoints available			No breakpoints available		
M. catarrhalis	40	0.03	0.12	No breakpoints available			No breakpoints available		
Enterococcus spp.	513	0.12	0.12	100	0	0	99	1	0
S. aureus	505	0.12	0.25	100	0	0	99.5	0	0.5
S. pneumoniae	70	0.5	1	No breakpoints available			No breakpoints available		

*ImpNS: Imipenem Non-Susceptible; **S: susceptible, I: intermediate, R: resistant.

Conclusions: Tigecycline exhibited potent in vitro activity against the majority of the clinical isolates in this study. Species with the highest MICs recorded were *S. pneumoniae* among Gram-positive cocci and *Enterobacter* and *Acinetobacter* spp. among Gram-negative bacteria. Interpretation of the results, using the different breakpoints established by the two organisations, may influence substantially the resistance rates reported for *K. pneumoniae* and *Enterobacter* spp.

P688 Analysis of resistance and vancomycin "reverse creep" in Latin American *Staphylococcus aureus*: ten-year report of the SENTRY Antimicrobial Surveillance Program (1997–2006)

R. Picao, H. Sader, R. Jones, S. Andrade, A. Gales (Sao Paulo, BR; North Liberty, US)

Objectives: To evaluate the antimicrobial susceptibility (S) rates of *S. aureus*, including meticillin-resistant (MRSA) strains, collected in Latin American medical centres as part of the SENTRY Antimicrobial Surveillance Program. The Brazilian MRSA clone is highly prevalent in the region and usually shows high rates of antimicrobial resistance.

Methods: A total of 8,705 *S. aureus* referred from seven Latin American countries during a 10-year period (1997–2006) were S tested to 13 antimicrobials by CLSI broth microdilution methods. The frequencies of *S. aureus* with vancomycin MIC values ⩾1 mg/L collected by 7 of 10 medical centres that participated in the programme since 1999 were analysed by comparing two time periods, 1999–2001 and 2002–2006.

Results: Overall, 37.3% of strains were MRSA. Brazil contributed with the majority of *S. aureus* (3517/40.4%) and MRSA (1443/41.1%) strains. S rates are shown in the table. MRSA rates increased from 33.8% in 1997 to 40.2% in 2006 ($p = 0.007$). S rates for many non-β-lactam agents increased among MRSA as follows (1997/2006): clindamycin (13.2/16.3%), erythromycin (3.9/8.6%), gentamicin (7.8/27.3%), tetracycline (29.9/79.5%), co-trimoxazole (30.9/67.0%). Chloramphenicol and rifampin S rates increased from 25.5% and 48.5% in 1997 to 65.6% and 60.7% in 2005, respectively. All increases in S rates among MRSA were statistically significant ($p < 0.05$), except for clindamycin. Interestingly, the percentage of *S. aureus*/MRSA with vancomycin MIC ⩾1 mg/L decreased from 93.9/96.6% in 1999–2001 to 86.7/92.3% in 2002–2006 ($p = 0.00001$).

Antimicrobial agent	MRSA (n = 3253)			MSSA (n = 5452)		
	MIC (mg/L)		% S	MIC (mg/L)		% S
	50%	90%		50%	90%	
Ciprofloxacin	>4	>4	8.3	0.25	0.5	96.2
Clindamycin	>8	>8	12.4	0.12	0.25	98.0
Gentamicin	>8	>8	15.6	⩽2	⩽2	95.9
Erythromycin	>8	>8	6.9	0.25	8	82.1
Linezolid	2	2	100.0	2	2	100.0
Teicoplanin	⩽2	2	100.0	⩽2	⩽2	100.0
Co-trimoxazole	>2	>2	65.1	⩽0.5	⩽0.5	98.8
Vancomycin	1	1	100.0	1	1	100.0

Conclusions: The increase in the MRSA rates coupled with increased S rates to non-β-lactam agents and decrease in the frequencies of strains with vancomycin MIC ⩾1 mg/L ("reverse creep") may indicate the emergence and dissemination of new MRSA clones, distinct from the Brazilian clone, in the Latin American countries surveyed by the SENTRY Program.

P689 Frequency and antimicrobial susceptibility profile of vancomycin-resistant enterococci from Latin America: a report from the SENTRY Antimicrobial Surveillance Program (1997–2006)

A. Gales, H. Sader, K. Santiago, A. Pgnatari, R. Jones (Sao Paulo, BR; North Liberty, US)

Objective: To evaluate the prevalence and susceptibility profile of vancomycin-resistant enterococci (VRE) in Latin America. VRE emerged nearly twenty years ago in the United States (USA) and rapidly disseminated in many USA hospitals; however, its prevalence seems to remain relatively low in Latin America.

Methods: As part of the SENTRY Antimicrobial Surveillance Program, a total of 2026 enterococci isolated between January 1997 and December 2006 from Latin American hospitals were studied. The susceptibility profile to nine antimicrobial agents was determined by CLSI broth microdilution methods and results interpreted according to CLSI document M100-S17 (2007).

Results: *E. faecalis* (78.2%) and *E. faecium* (12.7%) were the most frequently isolated species. Blood (41.4%) and skin/soft tissue (11.0%) represented the most frequent body sites of infection. A total of 112 (5.5%) strains were identified as VRE, with 46% of them being isolated in Brazil. The VRE frequency increased from 0.0% (1997 and 1998) to 10.3% (2006), with an important increase after 2002. Although the numbers of *E. faecalis* and *E. faecium* exhibiting the VRE phenotype were similar, the percentage of vancomycin-resistant *E. faecium* (VR-EFM; 19.7%) was proportionally higher than vancomycin-resistant *E. faecalis* (VR-EF; 3.3%). A significant increase in VR-EFM isolates was detected in Brazil between 2005 and 2006. VRE was most frequently isolated from urine (18.5%). The antimicrobial susceptibility profile of VRE isolates is summarised in the table. Linezolid and tigecycline were the most active compounds tested against VRE. In contrast, the majority of VRE were resistant to teicoplanin (vanA pattern).

Antimicrobial agent	VR-EF (53)			VR-EFM (51)		
	MIC_{50}	MIC_{90}	%S	MIC_{50}	MIC_{90}	%S
Ampicillin	4	16	86.8	>16	>16	2.0
Teicoplanin	>16	>16	3.8	>16	>16	5.9
Gentamicin-HL	>1000	>1000	18.9	⩽500	>1000	76.5
Streptomycin-HL	⩽1000	>2000	83.0	>2000	>2000	15.7
Quinupristin/dalfopristin	>2	>8	1.9	1	>2	68.6
Linezolid	1	2	100.0	1	2	100.0

Conclusions: An important increase in the frequency of VRE has been observed in Latin America and appears to be associated with the dissemination of endemic clones expressing the vanA. Linezolid and tigecycline were the only antimicrobials with broad activity against *Enterococcus* spp. independent of the species identification or glycopeptide phenotype.

P690 Prevalence of vancomycin-resistant *Enterococcus* spp. and associated resistance patterns among isolates collected over a decade of SENTRY Program surveillance in North America

M. Castanheira, D. Biedenbach, H. Sader, T. Fritsche, R. Jones (North Liberty, US)

Objective: To investigate the susceptibility pattern of *E. faecalis* and *E. faecium* in the USA and Canada medical centres over 10 years;

secondarily, to analyse trends in vancomycin-resistant *Enterococcus* spp. (VRE) in North America during the same period.
Methods: Isolates from bloodstream infection (BSI; 7,284) and other sources (2,763; mainly urine and wound) recovered as part of a 10-year surveillance programme (1997–2006) were analysed for susceptibility profiles. Isolates were collected from medical centres in the USA (52) and in Canada (8) and were tested at a central laboratory (JMI Laboratories, North Liberty, IA) using CLSI broth microdilution methods and interpretation criteria.
Results: Overall, the VRE rate was higher in BSI (19.1%) compared to other sources (14.5%). In the USA, VR *E. faecalis* rates were stable over ten years (3.3%) with significant year-to-year variation but without trending. In contrast, VR *E. faecium* steadily increased from 50 to 70%. The percentage of vanA phenotype increased in both species over the years, becoming the predominant resistance phenotype in more than 85% of VRE isolates. The table shows the yearly progression of VRE BSI isolates in the USA and van phenotypes. In Canada, VRE was documented in <1% of BSI isolates and included *E. faecium* only. Higher resistance rates to other agents were noted among VRE compared to susceptible strains. These included ampicillin-resistant *E. faecalis* at 13%, ciprofloxacin-resistance at ⩾95% for both species and high-level gentamicin and streptomycin resistance rates were 20–40% higher among VRE compared to vancomycin-susceptible strains. Linezolid-resistance was 1.3% and 2.5% among VR *E. faecium* and *E. faecalis*, respectively, compared to <0.5% among vancomycin-susceptible isolates.
Conclusions: At the beginning of this study (1997), VRE were considered to be primarily a USA problem. As expected, VRE has disseminated within other countries, becoming a worldwide concern. The spread of VRE in North America warrants continued susceptibility profiling of large numbers of isolates from multiple medical centres to track changes. The 20% *E. faecium* VR increase in the USA (nearly all caused by the presence of vanA) and an associated increase in co-resistance has been alarming. Other countries should take note of the USA VRE experience and initiate infection control measures to limit this important pathogen from becoming widely endemic.

	Year

Biofilms

P691 Effect of fluoride content of the oral biofilm on the surface structure of titanium

E. Urbán, A. Stájer, K. Turzó, E. Mihalik, Z. Rakonczay, E. Nagy, M. Radnai (Szeged, HU)

Background: High fluoride concentration and the low pH in prophylactic mouthwash and gels used to prevent caries may modify the surface structure of the transgingival region of implants made of titanium (Ti). Fluoride, like a reductive agent may have an opposite effect and attack the oxide layer. The aim of the present work was to study whether the changes on the surface structure of Ti caused by high fluoride concentration and acidic pH alter the adherence and colonisation of bacteria.
Methods: Polished commercially pure titanium CP grade 4 discs (Camlog) were used. Each sample was treated for 1 hour with one of the solutions: mouthwash containing 0.025% fluoride, a gel containing 1.25% fluoride and a solution of 1.0% NaF (pH 4.5). The surface structures were analysed by atomic force microscopy (AFM) and X-ray photoelectron spectroscopy (XPS). The colonisation of *Porphyromonas gingivalis* strains was studied by scanning electron microscope (SEM) after 5 days of anaerobic incubation and the quantity of the bacterial protein was determined by commercially available kit (Pierce).
Results: The roughness of the treated sample surfaces (Ra), as revealed by the AFM measurements, was increased significantly (2 times for the gel and 10 times for the 1% NaF solution) as compared to the control surface. No changes were detected in case of the mouthwash. The high fluoride concentration and acidic pH in the case of the gel and the 1% NaF solution resulted in a strong corrosion and a modification of the composition of the titanium surface. The XPS spectra revealed formation of fluoride containing complexes (NaF and Na2TiF6) bound strongly to the surface. A correlation was revealed between the roughness of the surface and the thickness and the maturity of the *P. gingivalis* bacterial colonies developed on the titanium surface. The number of the bacteria was significantly increased due to the changes in the surface caused by NaF treatment.
Conclusions: High fluoride concentration and acidic pH increase the roughness of the titanium surface. Bacterial biofilm colonisation on this rough surface was proved to be more mature. The present study indicates that high fluoride concentration and acidic pH may affect the development of transgingival epithel junction on the Ti surface.
This work was supported by the GVOP-3.2.1.-2004–04–0408/3.0 project funded by the EC and the Hungarian Ministry of Economy, and the ETT project (434/2006) supported by the Hungarian Ministry of Health.

P692 Are silver-coated Foley catheters resistant to encrustation by crystalline bacterial biofilms?

S.D. Morgan, D.J. Stickler (Cardiff, UK)

Objectives: To examine (1) the vulnerability of silver-coated silicone and silver/hydrogel-coated latex catheters to colonisation by crystalline *Proteus mirabilis* biofilm; (2) to determine the extent to which silver ions elute into urine from these catheters.
Methods: Laboratory models of the bladder were fitted with size 14 Rüsch silver-coated silicone catheters or Bard IC silver/hydrogel-coated latex catheters. Rüsch all-silicone catheters were used as non-coated controls. Models were supplied with artificial urine at 1 ml/min and inoculated with 10 ml of a 4 h urine culture (2 x 10^8 cfu/ml) of *P. mirabilis* NSM6, a test strain that had been isolated from the blocked catheter of a patient. Models were operated until the catheters blocked. Scanning electron microscopy was used to visualize the biofilms that had developed on the catheters. The silver content of urine flowing from the catheters over three day periods from models that had not been inoculated was assayed by atomic absorption spectroscopy.
Results: The mean times the models took to block calculated from data obtained from five replicated experiments were 54.3±15.8h for the silver/hydrogel-coated catheters, 73.5±23.0h for the silver/silicone devices and 65.0 ±11.3h for the controls. Analysis of variance revealed no significant differences between these mean values (P = 0.257). Scanning electron microscopy confirmed that catheter blockage was due to crystalline biofilm formation. The eye-hole and lumenal surfaces of all three types of catheter were shown to be colonised by extensive co-aggregates of cells and crystals. Analysis of urine failed to detect silver in the urine draining from the catheters (limit of detection 0.05 mg/L). At blockage the mean viable cell populations in the urine from the models were 1.8 x 10^7 cfu/ml for the control, 3.4 x 10^7 cfu/ml for the silver/silicone catheter and 2.9 x 10^7 cfu/ml for the silver/hydrogel catheter. One-way analysis of variance revealed no significant difference in these mean values (P = 0.148).
Conclusions: The silver-coated silicone and the silver/hydrogel-coated latex catheters are equally vulnerable to encrustation and blockage by crystalline bacterial biofilm. The concentrations of silver eluting into urine from these catheters are less than 0.05 mg/L and are not antibacterial.

P693 ***Staphylococcus aureus* biofilm eradication: a new approach by phodynamic therapy**

F. Giuliani, M. Becherelli, L. Fantetti, G. Roncucci (Siena, IT)

Introduction: Biofilms have remarkable medical importance for several infections. Today bacterial biofilm properties are not fully understood and strategies for their treatment remain undeveloped. Standard antimicrobial treatments often fail in biofilm eradication and chronic infections can arise. The development of alternative therapies against biofilm infections represents one of the major public health concern. Recently, photodynamic therapy (PDT), is receiving considerable interest for its potential as antimicrobial therapy. The principle of PDT is rather simple: a photosensitizer is taken up into cells and activated by light of appropriate wavelength causing cell death through the production of active oxygen species (ROS).
Objectives: The aim of this study was to investigate the efficacy of cationic Zn(II)phthalocyanines (PC) of novel synthesis as photosensitizers for selective in-vitro eradication of *S. aureus* biofilm.
Methods: *S. aureus* ATCC 6538 biofilm was carried out in a 96-wells flat bottom sterile polystyrene microplates. After 24h incubation at 37ºC, appropriately diluted Zn(II)PC solutions (0.05–50 microM) were added to each well. After 5 min incubation in the dark Zn(II)PC-treated biofilms were irradiated with red light (30 J/cm^2). Biofilms residual vitality after photoinactivation was determined by XTT assay. Cell survival was expressed in terms of the percentage inhibition of XTT formazan production (measured at 450 nm) by treated biofilms compared with values obtained for untreated biofilms.
Results: The antibacterial kiling effects on the *S. aureus* biofilms, after photodynamic treatment with cationic Zn(II)PC, were linear in a concentration-dependent manner. The 50% cell killing was obtained at a very low concentration 0.05 microM with the most effective compound and at least 95% killing was caused by all the Zn(II)PC tested at higher concentration (50 microM).
Conclusion: Our results have shown that cationic Zn(II)PC photosensitizers in conjunction with red light (600–700 nm) of moderate intensity display a potent in vitro activity against sessile *S. aureus* cells. The photodynamic inactivation by Zn(II) PCs resulted more effective or rapid than vancomincin, one of the most common antibacterial agents used for the Sthaphylococcus spp. treatment, indicating their potential usefulness for the eradication of *S. aureus* biofilm-associated infection.

P694 **The possible role of the LPXTG protein SesC in *Staphylococcus epidermidis* biofilm formation**

M. Shahrooei, V. Hira, B. Stijlemans, R. Merckx, P. Hermans, J. Van Eldere (Leuven, Brussels, BE; Rotterdam, Nijmegen, NL)

Objective: Several well-studied proteins with defined roles in *Staphylococcus epidermidis* biofilm formation (Aap, Bhp, SdrF and SdrG) are LPXTG motif containing proteins. We investigated the involvement of another LPXTG protein (SesC -Accession: NP_765787-Bowden et al. Microbiology. 2005; 151:1453) in biofilm formation.
Methods: Different clinical isolates of staphylococci were tested for the presence of sesC by PCR. Our previously described in vitro and in vivo rat models were used to investigate the time course of gene expression in planktonic and sessile bacteria during biofilm formation and persistence. A recombinant protein of SesC was produced and used to raise polyclonal antisera in rabbits. Immobilised recombinant SesC was used for polyclonal antibody purification from rabbit serum. ELISA and Western blot were performed to demonstrate the presence of SesC in the cell-wall fraction. Purified anti-SesC IgG's and FITC-labelled goat-anti-rabbit antibodies were used in immunofluorescence assays to study in vitro protein expression and the effect on biofilm formation. The sesC gene was cloned in pCN68 (AEM. 2004, 70:6076) and expressed in sesC negative strains of *S. aureus* RN4220 and a clinical isolate of *S. haemolyticus*. Biofilm formation ability of transformed strains was compared to that of wild strains.
Results: The sesC gene was present in all *S. epidermidis* strains. The expression of sesC was significantly upregulated during the early and late in vivo infection. A small statistically not significant difference in gene expression between sessile and planktonic bacteria was observed in vitro. Fluorescence microscopy data confirmed the gene expression study data. Furthermore, we demonstrated that polyclonal antibodies against SesC reduced in vitro *S. epidermidis* biofilm formation. Expression of sesC in non *S. epidermidis* strains didn't lead to any significant difference in biofilm formation ability of the transformed strains.
Conclusion: The presence of sesC in all tested *S. epidermidis* strains but not in all other staphylococcal species indicates the importance of sesC for *S. epidermidis*.
The observed upregulation in sessile bacteria and the ability of polyclonal anti-SesC antibodies to inhibit biofilm formation in *S. epidermidis* suggest a role for SesC in the *S. epidermidis* biofilm formation. The precise role in biofilm formation of this protein remains to be solved.

P695 **Detection of staphylococcal ability for biofilm formation in otitis media in children. An evaluation of three different detection methods**

A. Niedzielski, J. Paluch-Oles, M. Koziol-Montewka, A. Magrys, G. Niedzielska, M. Kotowski (Lublin, PL)

Objectives: Chronic otitis media (OM) is a common paediatric infectious disease. The infection has long been considered to be a sterile inflammatory process. The previous application of highly sensitive techniques of molecular biology suggests that metabolically active bacteria exist in culture-negative paediatric middle-ear effusions. To explain these observations it has been previously proposed that chronic OM may result from a mucosal biofilm infection. Bacterial biofilms are difficult to detect in routine diagnostics and are inherently tolerant to host defences and antibiotic therapies. In addition, biofilms facilitate the spread of antibiotic resistance by promoting horizontal gene transfer. The purpose of this study was to analyse a phenotypic and genotypic ability of isolated staphylococcal strains for biofilm formation during the course of otitis media in children by using three different detection methods.
Methods: A total of 96 effusions from the mid-ear, obtained from 48 patients aging between 2 and 6 with chronic otitis media, were tested bacteriologically by conventional methods. The identification to species level was performed by using API tests (Bio Merieux). Among 36 culture positive specimens, 16 strains of *Staphylococcus* spp. were screened for biofilm formation by tissue culture plate (TCP), Congo red agar (CRA) method and presence of ica A, B, C, D operons.
Results: Of 16 *Staphylococcus* spp., Api Staph revealed 8 strains of *S. epidermidis*, two S. sciuri, one *S. capitis*, one *S. caprae*, one *S. warneri*. The remaining three strains were identified as *S. aureus*.
Regarding coagulase negative Staphylococci (CNS) isolates, 6 (37.5%) revealed the phenotypic ability to produce biofilm, confirmed by TCP and CRA methods. Three of these isolates (18.7%) were also icaA and icaD positive and slime forming. Two *S. aureus* strains, detected as icaA or icaB positive by PCR analysis displayed a biofilm-negative phenotype in TCP and CRA methods.
Conclusion: Among the *Staphylococcus* genus, the species that is most commonly involved in biofilm formation is *S. epidermidis*. Biofilm formation is encoded by the ica operon and coexpression of icaA and icaD is required for full slime synthesis. TCP method correlates with the results of ica detection and is more specific than CRA.

P696 ***Staphylococcus epidermidis* biofilm modulates cytokine production**

A. Spiliopoulou, F. Kolonitsiou, I. Spiliopoulou, M. Krevata, G. Dimitracopoulos, E. Anastassiou (Patras, GR)

Objectives: To compare the immune response of *Staphylococcus epidermidis* bacterial cells existing either in planctonic or in biofilm phase.
Methods: A reference slime producing *S. epidermidis* strain (ATCC35983) was used in the present study. Slime production was

confirmed by Christensen's method. Planctonic phase bacteria were obtained after a 6h incubation in proper medium. Biofilm phase bacteria were obtained by incubation in 24-well tissue culture plates for 48h and subsequent rinse; biofilm phase cells remained attached to the bottom of the wells. Peripheral blood mononuclear cells from multiple healthy donors were isolated and co-cultured in 24-well flat bottom tissue culture plates either with live *S. epidermidis* planctonic cells at a ratio of 25:1 or with biofilm phase cells. Cytokines were measured in triplicate, using the Luminex® xMAP™ technology, in cell-free supernatants collected at 2, 4, 6, 12, 24 and 48 hours. The 8-plex assay kit was used for the simultaneous quantitative determination of the following cytokines: TNFa, IL-1b, IL-6, IL-8, IL-10, IL-12p40, IL-13 and GM-CSF, whereas, the 3-plex high-sensitivity assay kit was used for IL-12p70, IL-2, and INF-g.

Results: Kinetics of cytokine production revealed that TNFa and IL-10 accumulation was higher at 12h, whereas IL-12, IL-2, INF-g, and GM-CSF peaked at 48h. IL-1b, IL-6 and IL-8 levels exhibited a plateau pattern between 6 and 48h. IL-13 was not detectable in most experiments. Biofilm phase bacteria elicited production of lower levels of all cytokines tested as compared to planctonic phase bacteria. This phenomenon was more prominent for IL-12p40, as biofilm phase bacteria led to 35-fold lower IL-12p40 production. Although cytokines' levels showed interdonor variability, the overall pattern was reproducible in all experiments. Differences were statistically significant ($p < 0.05$). Mean peak value±standard deviation of each cytokine in pg/mL from a typical representative experiment is shown in Table 1.

	TNFa	IL-1b	IL-6	IL-8	IL-10	IL-12p40	IL-12p70	IL-2	INF-g	GM-CSF
Planctonic phase	5200 ±270	8500 ±460	9460 ±350	8900 ±550	212 ±30	120 ±18	1.79 ±0.3	3.04 ±0.26	5.7 ±1.5	130 ±14
Biofilm phase	210 ±25	749 ±60	420 ±35	2800 ±340	80 ±15	3.5 ±0.4	0.11 ±0.02	0.13 ±0.03	2.04 ±0.35	60 ±8

Conclusion: *S. epidermidis* cells embedded in biofilm induce low-level production of proinflammatory and adaptive immunity cytokines, especially IL-12p40, which is a key cytokine in development of TH1 responses leading to suppression of immune system, and may explain observed silent, persistent, infections.

P697 The coupled effects of physicochemical and flow conditions on *Staphylococcus epidermidis* adhesion and ica genes expression

A. Foka, M. Katsikogianni, V. Chini, Y. Missirlis, E.D. Anastassiou, I. Spiliopoulou (Patras, GR)

Objectives: Meticillin resistant *Staphylococcus epidermidis* (MRSE) is the predominant species associated with medical device infections impeding their long-term use. The critical step to development of infections is bacterial adhesion to biomaterials mediated by non specific interactions, as well as bacterial slime production encoded by the ica operon. The coupled effects of specific chemical terminal surface groups and flow conditions on the initial adhesion of *S. epidermidis* were investigated in correlation to the expression of two genes of the ica operon.

Methods: Reference control strains (ATCC35984, slime-positive and ATCC12228, slime-negative), and two clinical strains isolated from different hospitalised patients, (one ica-positive/slime-positive and one ica-positive/slime-negative) were investigated. Bacteria were grown in BHI medium and then suspended in physiological saline at a concentration of ~3×10^9 cells/mL. Hydroxyl (OH)-terminated (hydrophilic) and methyl (CH3)-terminated (hydrophobic) glass surfaces were used as substrates in a parallel flow chamber. Bacterial adhesion was examined under two flow rates: 2mL/min and 20mL/min for four hours. Total RNA from both bacterial supernatant (s) and adherent (a) bacteria after detachment with trypsin, was isolated by the Trizol method. Reverse transcription followed by quantitative Real-Time PCR (qRT-PCR) allowed the detection of expression levels of icaA and icaD. Table 1 summarizes the results.

Table 1: Quantification of *icaA* and *icaD* expression by qRT-PCR

Bacterial strain	Slime	qRT-PCR															
		icaA (copies/µL)								*icaD* (copies/µL)							
		(OH), ml/min				(CH_3), ml/min				(OH), ml/min				(CH_3), ml/min			
		2		20		2		20		2		20		2		20	
		s	a	s	a	s	a	s	a	s	a	s	a	s	a	s	a
ATCC 35984	+	0	0	8	0	0	0	13	5	80	52	583	56	104	114	1864	8
ATCC 12228	–	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
2264	–	1	0	0	2	5	0	0	4	11319	108	36	2	161	2	121	3
4388	+	3	0	3	1	8	5	0	3	3	31	6	11	39	297	56	5

Conclusions: Surface chemistry and flow conditions influence the expression level of both ica genes. Hydrophobic biomaterial surfaces and faster flow rate seem to play a crucial role to initial adherence increasing ica gene expression.

P698 In vitro activity of caspofungin and anidulafungin against *Candida albicans* and *C. glabrata* biofilms

A. Valentín, E. Cantón, J. Pemán, M. Bosch, M. Gobernado, J.P. Martínez (Valencia, ES)

Objectives: Candidiasis is frequently associated with biofilm formation on indwelling medical devices such as central venous catheters, urinary catheters, heart valves and joint prostheses. *Candida* spp. biofilms are less susceptible to antifungal agents than planktonic (free-living) cells. The aim of this study was to test the ability of *C. albicans* and *C. glabrata* to form biofilms and to determine the activity of caspofungin and anidulafungin against free-living cells and biofilms of both species.

Methods: 16 *C. albicans* and 23 *C. glabrata* strains from blood cultures were studied. MICs of planktonic cells were determined following the CLSI M27-A2 document. MIC2 corresponded to the lowest drug concentration that showed a reduction of growth $\geqslant$ 50% compared with the growth control. Biofilms were formed following the method described by Ramage. et al. (1). Antifungal agents at concentrations ranging from 16–0.03 mg/L were added to polystyrene microplates containing *Candida* biofilms of 24 and 48h of maturation. Antifungal activity against biofilms was assessed by the XTT reduction assay. Sessile MICs (SMICs) 50 and 80 corresponded to the lowest drug dilution that supported an OD $\leqslant$ 50% and $\leqslant$ 20%, respectively compared with control.

Results: 10 *C. albicans* and 3 *C. glabrata* developed biofilm (62.5 and 13.04%, respectively). Geometric mean SMIC50s and SMIC80s of caspofungin against *C. albicans* biofilms of 24/48h of maturation were 0.683/1.878 and $\geqslant$16/$\geqslant$16 mg/L, respectively; and against *C. glabrata* 0.038/0.12 and 0.095/0.12 mg/L, respectively. For anidulafungin, these values were: 0.521/4.52 and $\geqslant$16/$\geqslant$16 mg/L against *C. albicans* and 0.095/0.63 and 0.12/1 mg/L against *C. glabrata*.

Conclusions: *C. albicans* produced more biofilm than *C. glabrata*. Caspofungin and anidulafungin showed activity against *C. albicans* biofilms of 24h of maturation, but not against those of 48h. Both echinocandins displayed excellent activity against *C. glabrata* biofilms of 24 and 48h of maturation.

P699 Implication of *Candida* biofilm maturation on the susceptibility to amphotericin B, caspofungin and posaconazole, alone or in combination

S. Tobudic, C. Kratzer, W. Graninger, A. Lassnigg, A. Vorderwinkler, H. Fischer, E. Presterl (Vienna, AT)

Objectives: *Candida* biofilm-associated infections are a particular challenge in modern implant surgery because of their resistance to conventional therapy. In this work was determined the activity of amphotericin B, caspofungin and posaconazole alone or in combination on biofilms of various *Candida* species at distinct levels of maturation.
Material and Methods: Biofilms of 44 isolates from blood, central venous catheter, urine, skin swabs and medical devices swabs of cardiac surgery patients (*C. albicans* n= 25; *C. glabrata* n = 8, *C. parapsilosis* n = 5, *C. tropicalis* n = 2, *C. krusei*=1, *C. famata* n = 1, *C. norwegiensis* n = 1, *C. guilliermondi* n = 1) were grown for either 24, 48 or 72 hours in 96-well microtiter plates. The biofilms were treated for 48 hours with amphotericin B (AMB), caspofungin (CAS) and posaconazole (POS) alone in increasing concentrations according to the respective MIC (1–128×MIC) and with combination therapy: AMB 0.5 mg/l/CAS 0.5 mg/l or 1 mg/l, and AMB 0.5 mg/l/POS 0.5 mg/l or 1 mg/l. The optical density (OD) was determined using XTT-reduction assay at a wavelength of 450 nm. The OD of the untreated biofilm of the respective isolate was set as 1. To test for viable *Candida* spp. in the biofilms, the unfixed biofilms were scraped off and seeded to Sabouraud agar.
Results: Treatment with CAS reduced significantly the OD of 24- and 72 hours *C. albicans* biofilms at concentrations of 1×MIC ($p < 0.05$), while no significant reduction of the OD of 48 hours old non-*albicans Candida* biofilm was detected up to a concentration of 128×MIC. AMB reduced the OD of 24- and 72 hours biofilm significantly at concentration of 1×MIC – 4×MIC ($p < 0.05$). Significant OD reduction of 48 hours old biofilm achieved AMB at concentrations of 8×MIC (*C. albicans*) and 32×MIC (non-*albicans*). POS was equally effective at all stages of *Candida* biofilms and reduced the OD at a concentration of 1×MIC-2×MIC ($p < 0.05$). Combinations of antifungals led to significant reduction of the OD of the biofilm in the each stage of development ($p < 0.01$).
Conclusion: *Candida* biofilms show different degrees of susceptibility to therapy with a single antifungal agent depending of the phase of development. Particularly 48 hours old biofilms exhibit less susceptibility. Combination therapy attained high OD reduction and may be an option for the treatment of biofilm-associated infections.

P700 Comparison of biofilms formed by clinical oral isolates of non-*Candida albicans Candida* species

S. Silva, M. Henriques, R. Oliveira, D. Williams, J. Azeredo (Braga, PT; Cardiff, UK)

Objectives: Oral candidiasis is a significant problem in patients undergoing treatment for cancer or organ transplantation. Furthermore it is one of the most common and persistent conditions encountered in individuals with human immunodeficiency virus infection and acquired immunodeficiency syndrome. Many Non-*Candida albicans Candida* (NCAC) species, such as *Candida glabrata*, *Candida parapsilosis* and *Candida tropicalis* have recently emerged as significant pathogens of clinical importance. Biofilms have clinical significance as they exhibit high resistance to host defences and antimicrobial agents, therefore representing a persistent source of infectious organisms. Thus, the aim of this study was to compare biofilms formed by different oral isolates of NCAC species.
Methods: A total of 6 strains were isolated from oral tract, including *C. parapsilosis* (n = 2), *C. glabrata* (n = 2) and *C. tropicalis* (n = 2). References strains of each species (*C. glabrata* ATCC 2001, *C. tropicalis* ATCC 750 and *C. parapsilosis* ATCC 22019) were also assayed. Biofilms were analysed after 48 hours through total biomass quantification by crystal violet staining. The ultrastructure of the NCAC species biofilms was observed by Scanning Electron Microscopy. Matrix material was extracted from biofilms and their protein and total carbohydrate contents were determined by the Lowry and Dubois methods, respectively.
Results: The results showed that all NCAC species were able to form biofilms, although there were differences among species and strains. However, *C. glabrata* strains are less capable to form biofilm compared with the other species. *Candida parapsilosis* and *C. tropicalis* strains revealed a multilayer biofilm structure that consists of a dense network of yeast, hyphae and pseudohyphae. On the other hand, *C. glabrata* strains revealed a dense and compact multilayer biofilm structure intimately packed with yeasts without of either pseudohyphae or hyphae. Matrix isolated from *C. parapsilosis* biofilms consisted of higher amounts of carbohydrates but small amounts of proteins. In contrast, matrix from *C. tropicalis* strains consists mainly of proteins, with smaller amounts of carbohydrates. Matrix from *C. glabrata* strains consisted of lower amounts of proteins and carbohydrates.
Conclusions: As a general conclusion, it was possible to infer that clinical oral isolates of NCAC species present different behaviours in terms of biofilm formation, structure and chemical composition.

P701 In vitro anti-biofilm activity of micafungin in a lock strategy

E. Cateau, M-H. Rodier, J-M. Berjeaud, C. Imbert (Poitiers, FR)

Objectives: Catheter-related candidiasis are associated with the formation of a fungal biofilm which alters the susceptibility to antifungal agents. Catheter lock therapy could represent a conservative strategy of the catheter in candidaemia involving the static instillation, usually during 12h, of a concentrated solution of antimicrobial agent (100 to 1000 MIC) into the catheter lumen. This study deals with the in vitro anti-biofilm potential of micafungin, used as a lock solution, to manage *C. albicans* biofilms.
Methods: Biofilms of two *C. albicans* strains (ATCC 66396 and ATCC 3153), 12 hours or 5 days old, were formed on 0.5 cm sections of 100% silicone catheters. Micafungin 5 μg/mL (corresponding approximately to 170 MIC) was then added to the biofilms and catheters were incubated for 12h at 37ºC. Micafungin was then removed by washing. The metabolic activity of yeasts within the biofilm was assessed with XTT method, 24h, 48h or 72h after the end of the locks. Controls without antifungal were realised and used as references to calculate the inhibition percentages induced by micafungin locks.
Results: For a young *C. albicans* biofilm (12h), the growth inhibition induced by a 12h micafungin 5 μg/mL lock therapy and observed after a 24h culture without antifungal was at least 67% whatever the studied strain. 48h after the end of the lock, micafungin demonstrated a significant inhibitory activity on the development of 12h old biofilms, reaching at least 54%. 72h after the end of the lock, the inhibition observed was at least 40%.
The efficiency of micafungin lock on the development of a mature *C. albicans* biofilm (5 days old) was also significant: the inhibition observed 24h or 48h after the end of the lock was at least 54% suggesting a persistent efficiency.
Conclusion: These results showed that the micafungin lock treatment was efficient in vitro, on the studied strains, whatever the biofilm maturation stage. This study suggests that this echinocandin could have a real anti-biofilm potential and could become an interesting actor in the lock approach.

P702 CgCDR1, CgCDR2, and CgERG11 gene expression in *Candida glabrata* biofilms formed by bloodstream isolates

J.H. Shin, S. Kim, M. Shin, S. Suh, D. Ryang, S.J. Kee, S.I. Jung, S.J. Jang, H.S. Lee (Gwangju, KR)

Objectives: A number of molecular mechanisms have been implicated in non-biofilm antifungal resistance in *C. glabrata*, but the relevance of these mechanisms to *C. glabrata* biofilm cells has rarely been examined. We determined whether the expression of azole-resistance genes is altered during the developmental phases of biofilm formation by *C. glabrata*

Methods: Four bloodstream isolates of *C. glabrata* from cases of central venous catheter-related fungaemia showing high in vitro biofilm formation were studied. A microtiter-plate-based colorimetric assay was used to test the fluconazole susceptibility of *Candida* biofilms at 80% inhibition using the 2,3-bis[2-methyloxy-4-nitro-5-sulfophenyl]-2H-tetrazolium-5-carboxanilide (XTT) reduction assay. The expression of CgCDR1, CgCDR2, and CgERG11 genes during the early (6 h), intermediate (15 h), and mature (48 h) phases of biofilm development, and corresponding planktonic cells, were examined using real-time PCR methods.
Results: The fluconazole minimum inhibitory concentrations (MIC) of *C. glabrata* biofilms formed at 6, 15, and 48 h were all >1,024 ug/ml. The biofilms at 15 h exhibited an approximately 3.3-fold upregulation of CgCDR1 compared with the corresponding planktonic cells, which was higher than the values for biofilms at 6 (1.5 fold) and 48 (0.8 fold) hours ($P < 0.05$). The CgCDR2 transcript levels for biofilms were also highest at 15 h (3.1-fold upregulation), but were minimal at 6 and 48 h (0.5 and 0.8 fold) ($P < 0.05$). By contrast, the CgERG11 transcript levels did not differ among the 6-, 15-, and 48-h biofilms.
Conclusion: Our study demonstrated a temporal increase in the expression of the CDR1 and CDR2 genes in *C. glabrata* biofilms formed by bloodstream isolates during the early biofilm development stage.

P703 New focus – old disease: the paranasal sinuses as possible focus for bacterial lung infections in cystic fibrosis patients

H.K. Johansen, J. Fisker, T. Pressler, S.K. Hansen, S. Molin, N. Høiby, C. von Buchwald (Copenhagen, Lyngby, DK)

CF patients often have nasal polyposis and sinusitis because of impaired mucociliary clearance and mechanical obstruction of the sinus ostia by thickened mucus. CF patients who have had a lung transplant are colonised in their new lungs with the same clones as those that were cultured from their old lungs. It has therefore been suggested that the sinuses may serve as a bacterial reservoir after transplantation.
We have genotyped first and subsequent *P. aeruginosa* lung isolates from CF children by using the ArrayTube chip and PFGE. Among first isolates we found a large genetic diversity. We also found that after successful antibiotic eradication of *P. aeruginosa* new colonising isolates had the same genotype as the initial colonising strain. The large genetic diversity in CF children is distinct from most chronically infected patients in our CF clinic where the diversity of strains is more restricted.
Nineteen CF patients (7 males, 12 females, median age: 19 years (range 6–46)) have been treated with Functional Endoscopic Sinus Surgery using CT image guidance to evaluate whether their sinuses serve as a bacterial reservoir for their lung colonisation or infections. Seven patients were chronically infected with *P. aeruginosa*, 2 with *Burkholderia*, 1 with *Achromobacter* and 5 were intermittently colonised with *P. aeruginosa*. We found full or partial agreement between lung and sinus bacteriology in 18/19 (95%) of the patients. Seven patients chronically infected with *P. aeruginosa* have an identical genotype in their lungs for more than 15 years and this genotype was identical to the *P. aeruginosa* obtained from the paranasal sinuses. Four of five intermittently colonised children had growth of the same genotype of *P. aeruginosa* in their sinuses and sputum samples collected up to 2 years prior to the surgery.
In Gram stained smears from the sinuses we found that the bacteria were organised in biofilm structures similar to those seen in the lungs. In sinus smears we only detected few inflammatory cells compared to the lung smears. We think that the colonisation is immunological silent in intermittent colonised patients and cause only an insignificant anti-*P. aeruginosa* antibody response (Th1 response). When the bacteria grow in the lungs a shift towards a Th2 response is seen with high antibody production. In future, we will sample simultaneous sinus and lung cultures in intermittently colonised patients to determine the primary focus for the airway infection.

P704 Adhesion to and biofilm formation on IB3–1 bronchial cells by *Stenotrophomonas maltophilia*: implications in cystic fibrosis

G. Di Bonaventura, A. Pompilio, C. Picciani, M. Nicoletti, R. Zappacosta, R. Piccolomini (Chieti, IT)

Objectives: The increasing isolation of *S. maltophilia* from the sputa of cystic fibrosis (CF) patients has become a cause for concern in the CF community, as the organism is resistant to many of the antibiotics prescribed in the management of CF. However, the role of *S. maltophilia* in the physiopathology of CF pulmonary disease has not yet been clarified. The aim of the present study is to characterise the interaction between *S. maltophilia* and CF bronchial epithelium.
Methods: Twelve *S. maltophilia* strains from the sputum of CF patients were tested for adhesion to bronchial epithelial cells isolated from a CF patient (IB3–1; ATCC CRL-2777). IB3–1 monolayers were exposed for 2 h (37ºC, 5% CO2) to *S. maltophilia* 10^8 CFU/ml (MOI: 1.000), then adherence was measured by direct agar plating. The most adhesive strains (TC9 and TC10) were chosen for further characterisation. To determine the contribution of flagella to the ability to adhere to IB3–1 cells, fliI (codifying for the flagellum-associated ATPase) mutants of TC9 and TC10 strains were generated. Furthermore, swimming and twitching motility tests were performed. The significance of the difference ($P < 0.05$) was calculated by ANOVA-test and Neumann-Keuls test.
Results: All isolates tested adhered to IB3–1 cells, although striking differences were observed (mean±SD: $2.1\times10^6\pm1.7\times10^6$ cfu/chamber). In particular, TC9 and TC10 strains (causing monomicrobial and persistent infections) showed an adhesion (5.6×10^6 vs 5.0×10^6 respectively; $P > 0.05$) significantly higher than other strains tested. TC9 and TC10 strains significantly ($P < 0.01$) increased adhesion from 2 to 6 h incubation (TC9: 5.6×10^6 vs 9.3×10^6; TC10: 5.0×10^6 vs 1.1×10^7; 2h vs 6h, respectively). Microscopy showed that after 6h-incubation *S. maltophilia* forms structures consistent with biofilms. Adhesion levels did not correlate with flagellar motility. On the contrary, adherence of flagellar mutants fliI- TC9 and TC10 was significantly ($P < 0.001$) lower than wild-type strains (TC9: 2.5×10^6 vs 5.6×10^6, fliI- vs wt; TC10: 1.7×10^6 vs 5.0×10^6, fliI- vs wt).
Conclusion: Our results suggest, for the first time, that the ability to adhere to CF-derived bronchial epithelium is common in *S. maltophilia* isolates. Flagella function as adhesins in direct binding to IB3–1 cells. The ability showed by *S. maltophilia* to rapidly organise itself as a biofilm could have clinical relevance contributing to antibiotic resistance and bacterial persistence in CF patients.

P705 Mechanisms of environmental persistence of multidrug-resistant *Acinetobacter baumannii* isolates responsible for outbreaks in three Italian hospitals

P. Landini, G. Fugazza, M. Spalla, R. Migliavacca, E. Giacobone, A. Navarra, M. Labonia, L. Pagani (Milan, Pavia, San Giovanni Rotondo, IT)

Objectives: *Acinetobacter baumannii* (Ab), an environmental Gram-negative bacterium, is considered one of the most dangerous emerging pathogens. The increasing number of outbreaks by clonally related multidrug resistant (MDR) Ab underlines the importance of clonal spread in nosocomial infections. We investigated the mechanisms of persistence in the hospital environment of Ab isolates responsible for outbreaks in three Italian hospitals.
Methods: 52 clinical isolates, collected from 2 acute care hospital and 1 long-term and rehabilitation facility between 2002–2006, were identified and tested for susceptibility with standard procedures. Genotyping was performed by PFGE analysis. Biofilm formation was determined by crystal violet assay. To assess contribution of cellulose production to biofilm formation, cultures were grown in the presence of different concentrations of cellulase.
Results: Genotyping by PFGE showed that most of MDR Ab isolates, susceptible to carbapenems, able to cause recurrent outbreaks in the

studied settings belonged to the same DNA group (clone A), while the others, resistant to carbapenems too, belonged to clone B, which shows close relationship to European clone II. Both clone A and clone B isolates are proficient in biofilm formation, which was favoured by growth in nutrient-deficient medium in comparison to rich medium, and by lower growth temperature. Biofilm formation was inhibited by treatment with the lytic enzyme cellulase in both clones, suggesting that cellulose may act as an important adhesion factor in Ab. However, biofilms formed by clone A were less susceptible to cellulase treatment; in addition, clone A, but not clone B, displays a dark red phenotype on Congo Red-supplemented medium. These observations strongly suggest production of additional cell surface-associated structures involved in biofilm formation in clone A. Finally, clone A showed much stronger resistance to desiccation than clone B.
Conclusions: Our results show that biofilm formation in Ab is favoured in conditions more typical of the external environment rather than of the human host, confirming that biofilm might be involved in the Ab persistence in the environment. We show that cellulose is an important adhesion factor for Ab; however, the clone A identified in our study seems to possess additional biofilm determinants involved in resistance to environmental stresses such as desiccation, and thus potentially important in environmental persistence.

P706 *Aeromonas hydrophila* polar flagellum produces two redundant sodium-driven stator motor proteins

M. Wilhelms, A. Lacasta, J. Tomas, S. Merino (Barcelona, ES)

Aeromonas hydrophila is a ubiquitous water-borne bacterium that has been associated with a wide variety of human diseases, which include gastrointestinal and extraintestinal infections. Mesophilic aeromonads constitutively expressed a single polar unsheathed flagellum and 50%-60% strains can also produce multiple lateral flagella in hifhly viscous environments. Both flagella types are important virulence and colonisation factors.
Aeromonas polar flagella genes are distributed in five non-contiguous chromosomal regions and two of them contain genes whose encoded proteins are homologous to polar flagella stator-motor proteins. Polar flagella region 3 contains pomAB genes, and region 4 contains motX. Only motX mutation abolishes polar flagella motility. These results suggested that lateral flagella stator-motor LafT-U can supply PomA-B function or the presence of a second polar stator-motor involved in polar flagella motility.
The objective of this work is to completely characterise the polar flagella stator motor of *Aeromonas hydrophila* strain AH-3 and correlate polar flagella motility with biofilms formation.
Defined *A. hydrophila* AH-3 mutant in lafTU and a double mutant in both lafTU and pomAB, showed that both mutants are able to swim in liquid media. Then, transposon-insertion mutagenesis using the *A. hydrophila* pomAB mutant as recipient strain, allow us to identified a new chromosome polar flagella region (region 6) containing two polar stator-motor genes named pomC and pomD. *A. hydrophila* PomC and PomD are highly homologous to sodium-conducting polar flagella stator-motors. Distribution of pomAB and pomCD is identical in all the mesophilic *Aeromonas* strains tested, either if the strains were able to produce lateral flagella or not. Furthermore, analysis of *A. hydrophila* pomCD mutants and double mutants in both pomAB and pomCD showed that only double mutants abolish polar flagella motility.
Swimming motility assays in presence of different amiloride and sodium chloride amounts with *A. hydrophila* AH-3 and polar flagella stator-motor mutants demonstrate that PomA-B and PomC-D polar flagella stator-motor are sodium dependents. Biofilm assays showed that polar flagella motility is involved in biofilm formation.
In conclusion we demonstrated that PomA-B and PomC-D are redundant set of sodium-driven stator motor proteins, as none of them by separate is essential for polar flagella motility neither in aqueous nor high-viscosity environments.

P707 The AcrAB-TolC efflux system contributes to biofilm formation in *Salmonella enterica* serovar Typhimurium

M. Webber, C. Burrows (Birmingham, UK)

Objectives: To determine the role of the AcrAB-TolC efflux system of S. Typhimurium in biofilm formation.
Methods: Strains used were S. Typhimurium 14028 and isogenic derivatives lacking acrAB or tolC. Biofilms were grown in defined minimal media in microtitre trays or transwell trays and quantified by staining with 1% crystal violet and measurement of absorbance using a FLUOstar optima plate reader. RNA was prepared using the SV total RNA kit (Promega, U.K). Gene expression was determined using comparative RT-PCR and denaturing HPLC.
Results: Mutants lacking either acrAB or tolC were compromised in their ability to form biofilms compared to 14028. L829 (14028, tolC::aph) produced 3 fold less biofilm compared to 14028, L830 (14028, acrAB::aph) was further compromised in its ability to form biofilm and produced 10 fold less biofilm than 14028. Co-incubation of mutants lacking acrAB or tolC and 14028 separated by a membrane which acts as a barrier to cells but not solutes in transwell assays showed no rescue of biofilm formation. This suggested that the biofilm defect of L829 and L830 can not be alleviated by a molecule(s) secreted by wild-type strains. RT-PCR of acrB and tolC demonstrated that both genes were over-expressed (2-fold) by cells in a biofilm relative to cells grown in planktonic culture.
Conclusions: A functional AcrAB-TolC efflux system is required for normal biofilm formation in S. Typhimurium and expression of this system is increased during growth as a biofilm. It was not possible to rescue biofilm formation in the transwell experiments suggesting that AcrAB-TolC does not export a structural molecule required for creation of a biofilm. The data presented here demonstrate that AcrAB-TolC is required for biofilm formation as well as intrinsic resistance to many antimicrobials and pathogenicity as has previously been described.

P708 Differences in biofilm development and antibiotic susceptibility among human clinical Ureaplasma sp.

M. García-Castillo, M. Gálvez, M.I. Morosini, F. Baquero, R. del Campo, M.A. Meseguer (Madrid, ES)

Objectives: The aim of this work was to investigate the ability of clinical isolates of Ureaplasma sp. to be biofilm formers, comparing the antibiotic susceptibility between sessile cells (minimum biofilm inhibitory concentration, MBIC) and their planktonic counterpart (conventional MIC).
Methods: A total of 11 Ureaplasma sp. isolates were obtained from clinical samples that included urine, semen, and urethral exudates from urethritis or chronic prostatitis, and also from urine of two healthy volunteers. All isolates were recovered during 2007 at the Service of Microbiology of the University Hospital Ramón y Cajal, in Madrid, Spain and corresponded to unrelated patients. *Mycoplasma* identification was carried out by growth in 10C broth medium and growth of typical brown colonies on A7 medium by urease production in the presence of manganese chloride. Antibiotic susceptibility was determined by broth microdilution method. Biofilm susceptibility assay was performed in 96-well microtiter plates, using the 10-C UREA-medium pH 6. Bacterial biofilms was investigated by immersing the pegs of a modified polystyrene microtiter lid into this biofilm growth plate until the media turned from orange to fuchsia. Comparison between MBIC50-MIC50 and MBIC90-MIC90 values was carried out only in strains able to form biofilm.
Results: Positive biofilm formation was observed in 9 isolates (81.2%); being the two biofilm non-formers isolates obtained from urethral exudates. Taking into account the antibiotic susceptible-resistant concept, most Ureaplasma isolates were susceptible to all antibiotics used when the traditional MIC test were applied. However, the resistant isolates increased considerably when the antibiotic susceptibility test was carried out in biofilm formation. In general, MBIC were one or two dilution

higher than MIC, although there were some exceptions in which the MBIC was lower. These contradictory results were observed in four strains for telythromycin, levofloxacin, and tetracycline, observing a higher susceptibility for these antibiotics in the biofilm formation than in the planktonic one. Nevertheless, comparing the MIC50–90 with the MBIC50–90 in all biofilm-formers strains, MBIC values were higher for all antibiotics.
Conclusion: Ureaplasma sp. isolates from clinical human samples are able to growth in biofilm formation showing reduced antibiotic susceptibility compared with the planktonic one; although for some antibiotics MBICs are lower than MICs.

P709 Association between biofilm formation and antibiotic resistance by *Salmonella enteritidis*

I. Cirkovic, M. Svabic Vlahovic (Belgrade, RS)

Non-typhoidal salmonellosis in humans is usually a self-limiting disease confined to the gastrointestinal tract, but when infection spreads beyond the intestine, or when immunocompromised persons are affected, effective antimicrobial treatment is essential. Besides, numerous studies have shown that *Salmonella* spp. are capable of adhering and forming biofilm on diifferent surfaces and under different environmental conditions. The aim of this study was to analysed the association between antibiotic resistance and biofilm formation between tested strains of Salmonella Enteritidis.
A total of 30 strains of Salmonella Enteritidis were isolated from patients with acute diarrhoea at the Institute of Infectious and Tropical Diseases in Belgrade during 2002. The strains were identified and serotyped by conventional methods. Antimicrobial susceptibility testing for 11 antibiotics was performed according to the CLSI recommendations. The quantification of biofilm formation was performed by modified microtiter-plate test. Differences in the quantities of produced biofilm were examined by Friedman test, followed by the Wilcoxon signed ranks test. Statistical analysis of relationship between antibiotic resistance and biofilm formation was examined by Spearman coefficient of correlation.
Fully susceptibility to all antibiotics was established in 10 (33.3%) isolates, and 20 (66.7%) strains were intermediary susceptible or resistance to one or more antibiotics All isolates were sensitive to cefotaxime, gentamicin and ciprofloxacin. 13 (43.3%) isolates were resistant or intermediary susceptible to tetracycline, 8 (26.7%) isolates were resistant to nalidixic acid, ampicillin, and amoxicillin-clavulanic acid, while 3 (10%) were resistant to trimethoprim-sulfamethoxazole, chloramphenicol and kanamycin, and 2 (6.7%) was intermediary susceptible to cefuroxime. Among 27 (90%) biofilm producing isolates, 21 (77.8%) were weak, 2 (7.4%) was moderate, and 4 (14.8%) were strong biofilm producers. Antibiotic resistance was more frequently seen in biofilm-positive than in biofilm-negative isolates ($p < 0.05$). Statistical analysis showed correlation between resistance to antibiotics and the quantity of biofilm by bifilm producing strains of Salmonella Epidermidis.
Biofilm-positive isolates of Salmonella Enteritidis were more resistant to antibiotics than biofilm-negative isolates. Obtain results found an association between biofilm production and antibiotic resistance.

P710 Impact of antibiotics on biofilm and some other properties of *Klebsiella pneumoniae* in vitro

A. Hostacka, I. Ciznar (Bratislava, SK)

Objectives: *K. pneumoniae* is a pathogen responsible for different human infections and it is also involved in outbreaks of nosocomial infections. Antibiotic resistance of these bacteria have become a serious clinical problem. The effects of subinhibitory concentrations (sub-MICs) of ciprofloxacin, enoxacin, norfloxacin, gentamicin and netilmicin on biofilm formation, hydrophobicity, lipase and response to oxidative stress in two clinical *K. pneumoniae* strains (39, 61/P) were evaluated.
Methods: Microtiter plate assay for biofilm formation, adherence to xylene for hydrophobicity, spectrophotometric method with Tween 20 for lipase activity and effect of H2O2 for response to oxidative stress were applied.
Results: Biofilm production by the strain 39 treated with quinolones and aminoglycosides and by the strain 61/P with aminoglycosides was markedly decreased. The most effective concentrations (1/2 of the MICs) suppressed biofilm formation to 28.7–56.9% of the control levels. Quinolones to the lesser extent altered biofilm in strain 61/P. Though antibiotics in the most cases enhanced bacterial adherence to xylene, the strains remained in the hydrophilic state. Decreased lipase activity to the different range in the strains treated with all concentrations of quinolones (with the exception of norfloxacin and enoxacin in strain 39) and netilmicin and with some concentrations of gentamicin was found. Antibiotic treated bacteria in most of the cases showed higher sensitivity to oxidative stress (with the exception of norfloxacin), but in case of netilmicin in strain 39 no changes were observed.
Conclusion: *K. pneumoniae* treated with antibiotics manifested suppressed biofilm production and also altered adherence to xylene, lipase and response to oxidative stress in dependence on strain, type and concentration of antibiotic.
This work was supported by Ministry of Health of the Slovak Republic under the project Analysis of biofilm production in nosocomial strains as a basis to prevent infections in healthcare institutions 2005/24-SMU-02.

Bacterial CNS infections

P711 Rapid decrease of intrathecal cortisol levels correlates with severity of bacterial meningitis

O. Beran, O. Dzupova, M. Holub (Prague, CZ)

Objectives: Bacterial meningitis (BM) still represents an infectious disease with a significant morbidity and mortality. We have previously demonstrated that the elevated cortisol concentrations in the cerebrospinal fluid (CSF) are associated with the severity of BM and can also serve as useful diagnostic marker for differentiation from viral meningitis [Crit Care 2007]. Therefore, the present study was aimed at description of the kinetics of CSF cortisol levels during BM and assessment of its relationship to severity and distinct bacterial aetiology of the disease.
Methods: A total of 55 patients with BM were enrolled in the study. The BM severity was evaluated using APACHE II (Acute Physiology and Chronic Health Evaluation), SOFA (Sequential Organ Failure Assessment) and GCS (Glasgow Coma Score) scoring systems. Paired samples of CSF and serum were obtained on admission and 3–5 days later. Concentrations of cortisol were determined by radioimmunometric assay. Statistical analysis was performed using SPSS software^{TM}.
Results: Bacterial aetiology was confirmed in 42 BM patients (76%): *Neisseria meningitidis* in 17 cases (40%), *Streptococcus pneumoniae* in 14 cases (33%) and 11 cases were due to other bacteria. Increased CSF cortisol correlated with serum cortisol on admission as well as follow-up ($r = 0.60$, $p < 0.001$; $r = 0.78$, and $p < 0.001$, respectively). In addition, CSF cortisol levels on admission were associated with APACHE II ($r = 0.77$, $p < 0.001$), SOFA ($r = 0.68$, $p < 0.001$) and GCS ($r = -0.60$, $p < 0.001$). Also, CSF cortisol demonstrated a decrease between the initial and follow-up lumbar puncture ($p < 0.001$). Moreover, this decrease correlated with APACHE II ($r = 0.53$, $p < 0.001$), SOFA ($r = 0.51$, $p < 0.001$), and GCS ($r = -0.46$, $p < 0.001$). Although CSF cortisol concentrations were higher in pneumococcal meningitis compared to meningococcal meningitis, this difference was insignificant ($p = 0.12$).
Conclusion: Our results demonstrate that the initially elevated CSF cortisol levels rapidly decrease after administration of BM therapy (i.e. antibiotics and dexamethasone). Moreover, this reduction was more pronounced in patients with severe course of BM. The tendency of the association between the high CSF cortisol levels and pneumococcal aetiology of BM observed in our study should be further evaluated on a larger cohort of patients.
Acknowledgment: The study was supported by the grant IGA NR/9316–3.

P712 Spontaneous Gram-negative bacillary meningitis in adult patients

V. Pomar, N. Benito, R. Pericas, J. López-Contreras, M. Gurguí, P. Domingo (Barcelona, ES)

Objectives: The aim of this study was to describe the incidence, predisposing factors, aetiology, clinical features, complications, treatment and outcome of adult patients with spontaneous Gram-negative bacilli (GNB) meningitis (GNBM) during the last 25 years in a tertiary hospital.
Methods: We prospectively collected all cases of spontaneous bacterial meningitis occurring in adult patients at the Hospital de la Santa Creu i Sant Pau (Barcelona) between 1982 and 2006. Cases due to *Haemophilus influenzae* were excluded.
Results: Six hundred sixty-four patients with bacterial meningitis were registered. Forty of them were caused by GNB (6%). Twenty-three occurred in the first 12 years (56%) and 17 in the last 12 years (42%) (p= 0.27) with an overall incidence of 2 cases/100.000 patient-year. There were 23 (58%) men and the mean age was 63 years (SD 16 years). Underlying conditions were present in 29 patients (73%). An extrameningeal focus was found in 30 cases (75%): urinary infection in 13 patients (43%), and otitis/sinusitis and abdominal focus in 4 patients (13%), respectively. Nine episodes (22%) were nosocomial acquired.
The classic triad of meningitis (altered mental status, fever and neck stiffness) was found in 13 patients (32%). *Escherichia coli* was the most common cause (15 patients [38%]), followed by *Pseudomonas* spp. in 10 patients (24%). However, *Pseudomonas* spp. was the leading cause in nosocomial cases.
During the clinical course, neurologic complications occurred in 20 patients (50%) and systemic complications in 27 patients (68%). The overall mortality rate was 53% (21 patients). We found no significant difference ($p=0.678$) in mortality rates between two periods. To have underlying diseases, urinary infectious (versus other infectious focus) or developing acute renal failure were independent factors associated with a higher mortality (OR 9.8 [CI95% 1.2–77.6]; OR 8.7 [CI95% 1.2–64.3]; OR 11.7 [1.4–99.8], respectively).
Conclusions: Currently Gram-negative bacilli are an unusual cause of GNBM, accounting for 6% of all spontaneous meningitis in adults. No differences in the incidence were found over the 25-year period of study. Most of the patients have underlying diseases and this is a risk factor of higher mortality. The mortality rate is high (more than fifty percent of cases) and seems not to have decreased in the last years.

P713 Clinical features and prognosis factors of community-acquired acute bacterial meningitis in Spain

E. Sulleiro, D. Rodriguez, B. Almirante, R. Amaya-Villar, P. Fernández-Viladrich, C. Rodrigo, D. Fontanals, P. Catalan, M.A. Meseguer, J. Colomina, G. Prats (Barcelona, Seville, Madrid, Alzira, ES)

Objective: We conducted a multicentre study to determine clinical features and prognostic factors of community-acquired acute bacterial meningitis (ca-ABM) in nine hospitals of the Spanish Network for Investigation in Infectious Pathology (REIPI)
Methods: From Nov 2003 to Sept 2006 all patients >29 days diagnosed of ca-ABM were prospectively evaluated. The diagnosis was based on clinical condition, chemical and microbiological results in cerebrospinal fluid (CSF) and/or blood. Outcomes were classified as favourable or unfavourable (death or cure with disabilities). Predictors were identified through logistic-regression analysis.
Results: Four hundred and fifty five patients were included, 56% were men, the median age was 42 years (range: <1–91), *Streptococcus pneumoniae* (Sp) 43% were the most common aetiology agent followed to *Neisseria meningitidis* (Nm) 30%, *Listeria monocytogenes* (Lm) 13% and others 14%. Nm was the most common pathogen among patients $\leqslant$ 18 years (45.9%) and Sp in >18 years (80.7%). Predisposing conditions were oto-mastoiditis or sinusitis in 20% of the cases, previous immunosuppression (16.7%), diabetes (12.4%), CSF leak (8.5%) and alcoholism or cirrhosis (8.5%). The triad of fever, neck stiffness and altered mental status was present in 43.7% of the episodes. Rash was present in 20% of the cases, 12% had focal neurological deficits and 9% seizures. Penicillin susceptibility was tested in 146 Sp strains; of which 21.2% showed intermediate resistance (IR) and 4.8% resistance (R); of 119 Nm strains 6.7% presented IR to cefotaxim. Ampicillin susceptibility was tested in 39 Lm strains and all were sensible. Outcome was unfavourable in 26% of the cases with an overall mortality of 14%. In the multivariate model the unfavourable outcome risk factors appeared: age $\geqslant$65 years, respiratory failure, neurological deficits and seizures during treatment.
Conclusions: The most common pathogens causing ca-ABM in our area are Sp, Nm and Lm. Unfavourable outcome is high, so particular attention should be done to people with identified risk factors.

P714 Community-acquired acute bacterial meningitis in older people in Spain

E. Sulleiro, D. Rodriguez, R. Amaya-Villar, E. Garcia-Cabrera, P. Fernández-Viladrich, S. Molinos, A. Coloma, D. Fontanals, P. Catalán, M.A. Meseguer, J. Colomina, B. Almirante (Barcelona, Seville, Madrid, Alzira, ES)

Objective: Older age is considered to be an important risk factor for unfavourable outcome in community-acquired Acute Bacterial Meningitis (ca-ABM). The aim of this study is to describe clinical characteristics and outcome of ca-ABM in patients over 65 years compared to younger ones
Methods: A prospective multicentre study of ca-ABM was carried out in 9 Spanish hospitals included in the REIPI programme (Spanish Network for the Research in Infectious Diseases) between 1/11/2003 and 30/07/2006. Patients were diagnosed on the basis of a compatible clinical, biological and microbiological data. An adverse clinical outcome was defined as death or cure with disabilities.
Results: 415 patients were diagnosed with ca-ABM, 293 <65 years-old (median age: 29.8, range: 0–64) and 122 $\geqslant$65 years years-old (median age: 74.4, range: 65–91). Among patients over 65 years *Streptococcus pneumoniae* (Sp) was the most frequent aetiology (44.3%), followed by *Listeria monocytogenes* (Lm) (20.5%). Lm was significantly more frequent in this group compared to younger patients (20.5% vs 7.5%, $p<0.05$) among which *Neisseria meningitidis* (Nm) was the most common aetiology (12.3% vs 32.1%, $p<0.05$). Diabetes (28% vs 6%, $p<0.05$) and a distant foci of infection (12.7% vs 3.9%, $p<0.05$) were more frequent in elderly who more often presented the classic triad of fever, neck stiffness and altered mental status (50% vs 39%, $p=0.021$), a GSC (Glasgow Score Come) <14 (79.3% vs 50.2%, $p<0.05$), focal neurological deficits (21.2% vs 11%, $p=0.007$) and respiratory failure (23.7% vs 11%, $p<0.05$). Elderly cohort was treated with third-generation cephalosporin associated to ampicillin in 41% of the cases compared to only 18% of the cases in patients under 65 years ($p<0.05$). Among patients over 65 years hemodynamic failure (25.4% vs 12%, $p<0.05$), a GSC decrease on evolution (26.3% vs 13.8%, $p<0.05$) and an adverse clinical outcome (45% vs 20%, $p<0.05$) were significantly more frequent. Mortality rate was higher among adults over 65 years (29% vs 8%, $p<0.05$).
Conclusions: ca-ABM in patients over 65 years is predominantly due to Sp followed by Lm which is significantly more frequent in this group. Ca-ABM in the elderly cohort significantly present with more severe clinical features and adverse evolution being overall mortality in this group significantly higher.

P715 Secondary cases of meningococcal disease can be prevented by the immediate identification and eradication of the disease-causing strain of *Neisseria meningitidis* in close contacts

B.E. Kristiansen (Skien, NO)

Objective: To prevent secondary cases of meningococcal disease by the identification and eradication of the disease-causing strain in close contacts of the primary case.

Methods: Following the bacteriological verification of invasive meningococcal disease, the local physician is informed and "close contacts" (household members, kissing contacts, classmates, and playmates, children in the same kindergarten and others who have slept in the same room as the patients during the last 2 weeks before admission) are identified. On the same day or the following day, throat specimens are collected, plated and incubated at 37ºC in 10% CO_2. Upon growth the next day of oxidase-positive Gram-negative diplococci, colonies are picked and DNA extracted. A PCR amplicon restriction endonuclease analysis (PCR AREA) with primers from the folP-gene is performed. When the PCR AREA band pattern is identical with that of the disease-causing strain, contacts are given rifampicin.
Results: During the period 1988–2007 there have been 66 primary cases with meningococcal disease in the County of Telemark (165.000 inhabitants). No secondary case has been seen. The mean incidence of invasive meningococcal disease in all Norway during the first 10-years period (1988–1997) was 3.63/100,000 inhabitants/year (CI: 0, 52) and fell to 1.39 (CI: 0, 48) during the last period (1998–2007). The corresponding figures for the County of Telemark were 3.41 (CI: 1, 35) and 0.84 (CI: 0, 50), and in the 3 neighbouring counties the figures were 2.89 (CI: 2, 89) and 1.74 (CI: 0, 62). The disease-causing strain was found in 70 (3.1%) out of a total of 2252 contacts. The prevalence of the disease-causing strain was higher (14.8%) in household members and kissing contacts than in all other groups combined (1.7%). The odds ratio for carrying the disease-causing strain in household-members and kissing contacts was 8.74.
Conclusion: Secondary cases of meningococcal disease may be prevented by the rapid identification of the disease-causing strain in close contacts followed by subsequent eradication with rifampicin. Household-members and kissing contacts have the highest risk of carrying the disease-causing strain.

P716 Short-course therapy for adult meningococcal sepsis and/or meningitis: 23-year experience

C. Cabellos, R. Verdaguer, M. Cisnal, R. Pallares, X. Ariza, F. Gudiol, P.F. Viladrich (L'Hospitalet, ES)

Objective: Short course therapy for meningococcal disease have been previously shown as effective as longer therapies. In order to reinforce our results in adults we present our accumulated experience in 138 patients (pts) treated with a short course therapy for systemic meningococcal disease.
Patients and Methods: All pts admitted to our hospital with systemic meningococcal disease (positive blood or CSF culture or meningitis with petechial purpura) from January 1984 have been scheduled to a short 4 days antibiotic therapy and have been compared with the historical 7 days treated pts. Data were prospectively recorded in a 128 variables protocol.
Results: 138 adult pts (37 M/101 F) mean age 45.5±20 (18–87) were evaluated. Mean duration of therapy was 4.9±2 days, median 4 days. 17 pts presented shock on admission, 38 pts were treated with penicillin, 90 with ceftriaxone, 5 with cefotaxime and 4 with other drugs. Mortality was 13/138 (9%) due to early sepsis in 5 pts, neurological complications in 1 and late causes in 7. Mild neurological sequelae were present in 15 pts (12%). No relapses were observed after one month follow-up. When compared with pts treated previously with a 7 days or longer therapy course, 129 pts, (36 M/93 F) mean age 43.8±19 (18–80), mean duration of therapy 7.22 days, there were no differences in positive blood cultures, shock on admission (25 pts) mortality 12/129 (9%), due to early sepsis in 9 pts and neurological complications in 3, relapse (no cases) or sequelae 12 (10%) (NS). Antibiotic therapy in this long course therapy group consisted in penicilIin 119 pts, ampicillin 4 pts and chloramfenicol 6 pts.
Among short course therapy pts, in the subgroup of 16 pts presenting as sepsis without meningitis (1M/15 F) mean age 47.38±22 (18–82) with shock on admission in 3 pts treated for 4.6±2 days there were a mortality of 1/16 (6%), no relapses and sequelae were present in 1 patient without differences with the previously long-therapy treated pts. In the subgroup of 10 pts presenting as severe sepsis (hypotension or shock + thrombopenia + coagulation disorder with or without meningitis) with mean age 49.6 (21–73), shock in 7/10 and disseminated intravascular coagulation in 8/10 mortality was 3/10 (30%) all of them in the first day of therapy.
Conclusion: Short course (4 days) antibiotic therapy in adult meningococcal disease either meningitis or sepsis (including severe sepsis) is a safe therapy without relapses.

P717 Epidemiology of bacterial meningitis during a 5-year period in an infectious diseases unit in northern Italy

A.M. Azzini, C. Grigolo, A. Tedesco, E. Concia (Verona, IT)

Objective: To evaluate the frequency of isolation of *S. pneumoniae* (SP), *N. meningitidis* (NM), *H. influenzae* (HI), *L. monocytogenes* (LM) and other bacteria during meningitis, also defining their patterns of antibiotic susceptibilities, in order to optimise both prevention strategies and antibiotic therapy of this severe infection.
Methods: During a 5 years period (January 2002–June 2007) we prospectively evaluated patients affected by meningitis, in particular we collected their demographic data, the presence of co-morbidities and meningeal infection's predisposing factors. Liquor biochemical characteristic together with microbiological results were reported; the susceptibility test were performed by Kirby Bauer method.
Results: During the study period we collected 31 bacterial meningitis (BM), increasing from 2002 (4 cases) to 2006 (10 cases), with this trend confirmed during the first half of 2007 (6 cases). During the first three years period we found only SP as causal agent, but from 2005 NM has appeared and become predominant in relationship with other bacteria. During the study period we had only two LM (in 2002 and 2006) and one HI (2006). SP has never found to be penicillin resistant but in 25% of cases it showed an intermediate susceptibility to this antibiotic. 80% of NM was resistant-intermediate to penicillin. The only isolated HI didn't produce β-lactamases.
Conclusions: In our Institution BM is becoming more frequent than in the past, and this disagree with national data which show a trend in reduction from 2006. In particular we noted an increasing NM's frequency of isolation, with a predominance in last 3 years if compared with SP, which remained quite constant. This data are too limited to be interpreted as an outbreak but they call our attention to preventive interventions such as vaccination for this severe infection.
In contrast with European Antimicrobial Resistance Surveillance System data, the frequency of isolation of penicillin-resistant SP is low, but we frequently found penicillin resistant-intermediate NM. These antibiotic patterns support our empirical antibiotic approach to BM with ceftriaxone (2 gr bid i.v.) in association with levofloxacin (500 mg bid i.v.) which shows in vitro activity against LM as well. The effectiveness of this antibiotic treatment is proved by the mortality for BM as well, that was 0% during the study period.

P718 Laboratory-confirmed meningococcal disease in children over a 10-year period in Athens, Greece

E. Lebessi, M. Papadimitriou, G. Tzanakaki, M. Tsolia, A. Doudoulakakis, F. Lykou, V. Papaevangelou, K. Kallergi, J. Kremastinou (Athens, GR)

Objectives: Meningococcal disease (MD) may be presented clinically as septicaemia, meningitis, or both. Our study aimed to review the epidemiological data of MD, and to assess the phenotypes of *Neisseria meningitidis* in the paediatric population admitted to "P. & A. Kyriakou Children's Hospital" over a 10-year period.
Methods: The study population included patients with: (i) suspected invasive infection, meningitis and/or septicaemia and (ii) blood and/or CSF samples positive for *N. meningitidis*. All cases were laboratory-confirmed by culture and/or PCR. Culture, identification and serogrouping was carried out by standard methods. Susceptibilities to antimicrobials were determined by Etest. All isolates were sent

for serotyping and serosubtyping to the Hellenic National Meningitis Reference Laboratory. In addition, CSF and/or blood samples were also subjected to PCR for the detection of meningococcal DNA.
Results: During the study period, 235 cases of MD were recorded in patients (135 boys, 100 girls) aged from 15 days to 14 years (mean 5.1y±3.7SD). The clinical diagnoses were: meningitis associated with septicaemia (41.3%), septicaemia (40.0%), and meningitis (18.7%). In 150 cases (64%) the diagnosis was confirmed by PCR. The annual distribution of cases was: 15, 13, 39, 44, 53, 30, 15, 9, 10, 7 for the years 1998–2007, respectively. Most of cases (66%) occurred during the winter and early spring. Serogroup B accounted for 44.26% (104/235); serogroup A for 12.77% (30/235); serogroup C for 7.23% (17/235); serogroup W135 for 6.81% (16/235); serogroup Y for 0.85% (2/235); while non-serogroupable remained 28.09% (66/235). Serotype and subtype was determined in 72% of the isolates. A high differentation was observed among the phenotypes belonging to serogroup B. Phenotype B.4:P1.14 was most predominant (23.6%). All isolates were found to be susceptible to cefotaxime, and 82% to penicillin. Fully resistant strains were not found.
Conclusions: The epidemiological pattern of MD studied cases is similar to that found elsewhere in Europe. In contrast, the phenotype B.4:P1.14 (ST-269) is rarely found among the meningococcal strains isolated in other European countries. PCR is a valuable tool for the rapid diagnosis of meningococcal disease, as antibiotic prior sampling may reduce the diagnostic efficacy of the culture.

P719 Acute bacterial meningitis in an Athens childrens hospital over an 8-year period (2000–2007)

K. Papavasileiou, H. Papavasileiou, G. Tzanakaki, S. Chatzipanagiotou, H. Panagiotaki, J. Kremastinou, A. Voyatzi (Athens, GR)

Objective: this study describes the epidemiological and clinical features of bacterial meningitis in children for an 8-year period (2000–2007) in a paediatric hospital.
Materials and Methods: A total of 1630 hospitalised children with suspected clinical symptoms and signs of meningitis, aged between 16 days to 14 years, underwent a lumbar puncture. CSF and blood samples were investigated by laboratory methods such as white cell count in the CSF as well as cultures. In addition, all samples (blood and CSF) presenting >50 cells of polymorphonuclear type, were investigated by a multiplex polymerase chain reaction (PCR) for *N. menigitidis* (N.m), *H. influenzae* type b (H.inf) and *S. pneumoniae* (S.pn.) at the National Meningitis Reference Laboratory. All isolated strains were identified by using classical methods. Susceptibility test was performed by E-test according to CLSI guidelines. Serogroups were determined by slide agglutination test.
Results: Seventeen percent (17%, 272/1630) were found positive for meningitis; 219 (80.5%) had lymphonuclear predominance and 53 (19.5%) polymorphonuclear. Proven bacterial meningitis was diagnosed in 53 children with median age of 3–5 years. Males (157/272, 58%) outnumbered females. The most prevalent microorganism causing bacterial meningitis was N.m (n = 43, 81%) followed by *Enterococcus faecalis* (n = 3, 5.6%), S.pn (n = 2, 3.8%), *S. agalactiae* (n = 2, 3.8%), Enterobacteriaceae (n = 2, 3.8%) and *S. pyogenes* (n = 1, 2%). A high percentage (40%) of patients developed bacteraemia. Of the 43 meningococcal cases, 6 (14%) CSF samples were CSF culture and PCR positive while 37/43 (86%) cases were only PCR positive. Of those 23 (62%) were blood positive, 10 (27%) CSF and the remaining 4 (11%) were PCR positive for blood and CSF. The most predominant serogroup was B (53.5%), followed by A (14%), W135 (11.6%), C (2.3%) while 18.6% remained non-groupable (NG). The phenotype 4:P1.14 predominated among the serogroup B strains. The majority of S.pn strains belonged to serotype 18C. All strains were susceptible to antibiotics. Most cases occurred during winter (November-March).
Conclusions: After the use of vaccines (H. inf type b, N.m and S.pn) the frequency of bacterial meningitis has been decreased. N.m serogroup B:4:P1.14 was the prevalent cause of bacterial meningitis. No cases of H.inf meningitis was recorded. The use of molecular techniques contributed significantly towards more accurate and rapid recognition of bacterial meningitis infections.

P720 Epidemiology, clinical presentation and prognostic factors for death of bacterial brain abscess: a twelve-year review

M. Gutierrez-Cuadra, M.A. Ballesteros, A. Vallejo, C. Fariñas-Álvarez, E. Miñambres, D. Suárez, J.D. García-Palomo, A. Vázquez-Barquero, M.C. Farinas (Santander, ES)

Objective: Despite the advent of modern neurosurgical techniques, new antibiotics, and powerful imaging technologies, brain abscess remains a potentially fatal central nervous system infection. The aim of this study was to determine the epidemiological trends, prognostic factors, and outcomes of bacterial brain abscess.
Methods: Over a period of 12 years (1992–2005), 71 patients were retrospectively identified as having brain abscesses in a tertiary referral hospital in northern of Spain. Quantitative data are expressed as Mean (SD) and qualitative data are expressed in number and/or percentage (%).
Results: The mean age of the 71 patients was 45.2 years (10.6). There was a male predominance (73% of cases). Fever (28 patients, 30%), focal neurological symptoms (27 patients, 30%) and headache (19 patients, 26.8%) were the main clinical manifestations. The frontal lobe was the commonest anatomical site (28 patients, 41.2%). Bacteria were isolated from 33.8% of patients and monomicrobial infections occurred in 18 (37.5%) patients. No microorganisms were isolated in 23 (47.9%) patients. Staphylococci accounted for 33.5% of isolates and were the prevalent pathogens associated with haematogenous spread. Head and neck infections, neurosurgical procedures and immunosuppression were the main predisposing factors. Twenty seven (40%) patients underwent surgical procedures and 39 (57.4%) patients need anticonvulsive therapy. Fifteen (21%) patients died, most of them (12 patients, 29.3%) received only medical treatment. The most important univariate predictors of mortality were the presence of immunosuppression (P= 0.003), multiple organ failure in the ICU (P = 0.001), medical treatment alone (P = 0.05), multiple abscesses (P = 0.05), older age (p= 0.02), and the APACHE II score in the ICU. Logistic regression analysis showed that multiple organ failure (odds ratio [OR], 30.7; 95% confidence interval [CI] 1.8 to 514.1), multiple abscesses (OR 3.7; 95% CI 1.0 to 14.2), and delay to start antibiotic treatment after the diagnosis (OR 1.5 per day; 95% CI 1.1 to 2.1) were associated with a high mortality.
Conclusion: Despite the availability of new antibiotics and the development of better neurosurgical techniques, mortality of brain abscess is still high. Multiple organ dysfunction, abscess number, and delay to start antibiotic treatment after the diagnosis were associated with higher mortality.

P721 Is vancomicin necessary in empirical treatment of community-acquired meningitis?

R. Güerri, G. Vallecillo, F. Sánchez, E. Lerma, E. Solé, J. Villar, J.L. López-Colomés, R. Perello, A. Díez-Pérez (Barcelona, ES)

Introduction: Community Adquired meningitis is an important disease in our emergency departments. Empirical treatment is necessary in order to improve prognosis. National guidelines (SEIMC) include vancomicin combined with cefotaxime as first election therapy.
Objective: To study susceptibility to different antibiotics in community adquired meningitis reviewing initial empirical treatment, and determine whether the introduction of vancomycin in the empirical treatment provides some benefit
Methods: a descriptive retrospective study reviewing medical reports and microbiological cultures in patients admitted in the Emergency room of the Hospital Universitario del Mar, Barcelona (455 beds, and an area of influency of 500000 habitants) during 1 year (june 2006 to june 2007).
Results: 19 patients were admitted with community-adquired meningitis. 10 men and 9 women. Mean age 52 (range 23–78).

The most common causative organisms were *S. pneumoniae* 9 (47.3%), N. meningitidis 7 (36.8%) and *L. monocytogenes* 3 (15.9%).
Among *S. pneumoniae*, only 1 strains was resistant to Penicillin (Minimum inhibitory concentration (MIC) >0.1 μg/ml) but continued sensibility to cephalosporin and vancomicin. The rest of isolated strains had MIC < 0.5 μg/ml to cephalosporin group. Of *N. meningitidis* in 1 case was resistant to penicilin (MICs >1 μg/ml) and showed fully sensibility to cephalosporines and vancomicine. No resistance to tested antibiotics was observed in *L. monocytogenes*.
In the Emergency Department cefotaxime and vancomicin as empirical treatment was initiated in 11 patients (57%). Four patients died (all of them with combined treatment), from whom 3 had pneumococcical meningitis and 1 with meningococcical menigitis.
Conclusion: *S. pneumoniae* is the most frequent pathogen in community adquired bacterial meningitis in our population. All isolated *S. pneumoniae*, *N. meningitidis*, *L. monocytogenes* strains remained susceptible to currently used antibiotics in empirical treatment. Therefore, adding vancomicin as empirical treatment in community adquired meningitis does not improve any benefit, and theoretically only adds potential side effects and increased costs. However, monitoring the resistance rates in our community is necessary in order to adapt clinical guidelines.

P722 Scrub typhus central nervous system complications

D-M. Kim (Gwang-Joo, KR)

Background: *Orientia tsutsugamushi* spreads throughout the body via the bloodstream and lymphatics, and induces vasculitis leading to symptoms of systemic organ invasion.
Among these, meningoencephalitis is a life-threatening manifestation.
Methods: We conducted a prospective study of potential scrub typhus patients who were admitted to Chosun University Hospital between September 2004 and December 2006 to investigate the clinical and laboratory features of patients with scrub typhus meningoencephalitis and the therapeutic outcomes, and to determine the factors associated meningoencephalitis
Results: Multivariate analysis demonstrated that the presence or absence of pneumonia was significantly associated with the occurrence of scrub typhus meningoencephalitis (OR, 8.9; $P < 0.001$; CI, 2.9–27.2). Although appropriate antimicrobials such as doxycycline agents were administered at an early stage, meningoencephalitis still occurred.
Conclusions: Physicians should be aware of the possibility that meningoencephalitis could be developed during the course of appropriate drug therapy such as doxycycline. Close observation and intensive care are essential for patients with factors associated meningoencephalitis, particularly those with pneumonia. Increasing the dosage of doxycycline or administering antimicrobial agents such as rifampin with good penetration to the central nervous system, should be considered in such cases.

P723 Neurological complications of Mediterranean spotted fever

L. Ammari, A. Berriche, B. Kilani, H. Tiouiri, A. Ghoubantini, F. Kanoun, C. Fendri, T. Ben chaabane (Tunis, TN)

Background: Mediterranean spotted fever (MSF), a systemic *Rickettsia conorii*, is endemic in the Mediterranean region. It thought to be a benign disaese, but in 5–10% of cases, it is responsable for severe systemic manifestations. Neurological involvement has been reported in 28% of cases.
Objective: The aim of this study is to describe demographic characteristics, clinical presentation and outcome of neurological complications of MSF.
Methods: we conducted a retrospective study of patients who developped MSF with neurological involvement between January 1992 and June 2007 and admitted in the department of infectious diseases of Rabta Hospital in Tunis. The diagnosis of MSF was based on clinical criteria and/ or positive rickettsial serology.
Results: 16 patients with neurological manifestations of MSF were included, 15 male and 1 female. The mean age is 42.7 years. 9 patients are living in rural area and 10 owned dogs. Typical clinical signs are: fever (100%), headache (43.5%) and maculopapular rash (75%), inoculation eschar (62.5%). Neurological involvement includes: 7 meningitis (44%), 5 encephalitis (31%), 3 meningoencephalitis (19%) and 1 case of facial nerve palsy (6%).
Biochemical laboratory tests revealed: normal white blood cell count in 8 cases (50%), thrombocytopenia in 7 cases (44%), hepatic cytolysis in 10 cases (62.5%). A high level of lactate dehydrogenase is noted in 10 patients (62.5%). Lumbar puncture was performed in 14 cases. Analysis of cerebrospinal fluid revealed pleocytosis with normal glucose and protein levels in 12 cases (86%). Rickettsial serology was performed for 15 patients. Antibody titers against *Rickettsia conorii* detected by indirect immunofluorescence are positive in only 5 patients. Cerebral CT scan is normal in 3 cases. All patients received antibiotherapy: fluoroquinolone (11 cases), doxycycline (5 cases) for a mean duration of 13 days. Mechanical ventilation was initiated for 1 patient. Clinical outcome is favourable for all patients.
Conclusion: Rickettsial infection should be considered as a cause of neurological involvement in endemic areas. Early diagnosis and appropriate treatment are mandatory to prevent fatal issue of this potential complication of Mediterranean spotted fever.

Molecular studies with fungal pathogens

P724 Use of a new PCR to identify *Candida* species isolated directly from a positive blood culture

E. Roselló, N. Loaiza, V. Rodriguez, G. Codina, A. Andreu, A.M. Planes (Barcelona, ES)

Objective: Evaluation of a multiplex real-time PCR to identify *Candida* species from positive blood cultures.
Materials and Methods: A PCR technique to identify *Candida* was evaluated using: a) the fungus-specific universal primer pair, ITS3 and ITS4, to amplify a rDNA region (a portion of the 5.8S region, the ITSII region and a portion of the 28S region); b) five species-specific TaqMan probes to identify the most frequent species isolated in clinical samples (*C. albicans*, *C. parapsilosis*, *C. glabrata*, *C. tropicalis* and *C. krusei*); and c) a generic *Candida* TaqMan probe. The PCR was used on the supernatant of positive blood cultures shown to contain yeasts by Gram staining. DNA extraction was made using the EZ1 automatic system (Blood DNA protocol, Quiagen). For the PCR reaction, 5 μl from the extraction were transferred to a tube containing *C. albicans*, *C. parapsilosis* and *C. glabrata* species-specific TaqMan probes; if negative, the procedure was repeated with *C. tropicalis* and *C. krusei* species-specific TaqMan probes. Finally, if there was no amplification, the reaction was repeated with the generic *Candida* TaqMan probe.
Results: 73 blood cultures from 63 patients (32 males/31 females; 51 adults/12 children) were used. Patients were admitted to ICU (43%), surgery (28.5%), haematology and oncology (8%) and internal medicine wards (20.6%). Positive blood cultures were subcultured on blood agar, Sabouraud agar and CHROMagar *Candida*. Subcultures resulted in: 61 pure cultures, 12 mixed (yeast and bacteria) and 1 mixed to two *Candida* species. The species identified from different cultures were: 29 *C. albicans*, 19 *C. parapsilosis*, 18 *C. glabrata*, 6 *C. tropicalis*, 1 *C. lipolytica* and 1 *C. guilliermondii*. The first PCR (*C. albicans*, *C. parapsilosis* and *C. glabrata* species-specific TaqMan probes) correctly identified all *C. albicans* and *C. parapsilosis*, and 16 out of 18 *C. glabrata*. The second PCR identified all 6 *C. tropicalis*. The universal *Candida* PCR detected the remaining two species (*C. lipolytica* and *C. guilliermondii*). This PCR detected and identified, directly from blood culture, 94.6% of yeast causing fungaemia.
Conclusion: The proven real-time PCR permits the detection and identification of species causing candidaemia in less than three hours, while the conventional systems take at least 48 hours.

P725 Identification of *Candida* species by restriction enzyme analysis

R. Yis, M. Yücesoy (Izmir, TR)

Background: Identification of *Candida* species isolated from clinical specimens gives information about the antifungal susceptibility as well as sheds light to the choice of empirical treatment.

Objectives: This study was planned to apply restriction enzyme analysis (REA) for more rapid and reliable identification of *Candida albicans* and non *Candida albicans* species which had been previously identified by conventional methods and to compare the results.

Methods: In this study 146 *Candida* strains (40 *C. albicans*, 27 *C. parapsilosis*, 26 *C. tropicalis*, 25 *C. glabrata*, 11 *C. kefyr*, 10 *C. krusei*, and seven *C. guilliermondii*) isolated from various clinical specimens and *C. albicans* ATCC 14053, *C. parapsilosis* ATCC 90018 and *C. krusei* ATCC 6258 were included. The strains were identified according to germ tube test, morphology at cornmeal tween 80 agar and CHROMagar *Candida* and API 20C AUX system.

PCR was performed by using primers which targeted ITS1, 5.8S rDNA and ITS2 regions. PCR products were digested with MwoI enzyme for all species and with BslI for *C. parapsilosis* and *C. tropicalis* strains. Sequence analysis of four *C. albicans* and two *C. guilliermondii* isolates which resulted in different restriction patterns was performed.

Results: Calculated lengths of REA products obtained by MwoI enzyme are presented in the table. Restriction of *C. parapsilosis* and *C. tropicalis* isolates with BslI resulted in three bands of 413, 94 and 63 bp and three bands of 326, 187 and 63 bp, respectively. Three *C. albicans* isolates which produced a different restriction pattern had point mutations (guanine instead of adenine); one isolate had insertion/deletion type mutation and these mutations were the reason of a different pattern. In addition, sequence analysis of two *C. guilliermondii* isolates showing various fragments with different lengths were 66.6% similar with GenBank *C. guilliermondii* var. *guilliermondii* and 91.2% similar with *C. guilliermondii* var *membranaefaciens* (nucleotide seqeunce). Because of this high nucleotide sequence similarity, these isolates were accepted as *C. guilliermondii* var *membranaefaciens*.

Lengths of REA products, bp (no. of isolates)

C. albicans	*C. parapsilosis*	*C. tropicalis*	*C. glabrata*	*C. kefyr*	*C. krusei*	*C. guilliermondii*
141,84,261 (36)	336,146,88 (27)	325,154,97 (26)	414,174,171,86,80 (25)	370,430 (11)	289,134,83,54 (10)	355,302 (5)
184,141,165,95 (4)						390,300 (2)

Conclusion: As a result, we can conclude that restriction enzyme analysis with MwoI and BslI enzymes can be used for the identification of *Candida* species which need rapid identification or which are problematic with conventional methods that are still accepted as gold standard although some variations can be observed with this method.

P726 Nucleotide differences in internal transcribed spacer regions of rDNA and 5-flucytosine resistance among clinical *Candida dubliniensis* isolates in Kuwait

S. Ahmad, E. Mokaddas, Z. Khan (Safat, KW)

Objective: Clinical *Candida dubliniensis* isolates are classified into four genotypes based on nucleotide sequences of internal transcribed spacer (ITS)1 and ITS2 regions of rDNA. Some of the isolates from the Middle Eastern region are resistant to 5-flucytosine. This study was carried out to determine nucleotide differences in ITS region (including ITS1–5.8S rRNA-ITS2) of rDNA that define 5-flucytosine resistance among clinical *C. dubliniensis* isolates in Kuwait.

Methods: A total of 76 *C. dubliniensis* isolates recovered from various clinical specimens in Kuwait were assigned to one of four genotypes based on amplification of rDNA with genotype-specific primers. The susceptibility of the isolates to commonly used antifungal agents including 5-flucytosine was performed by Etest. DNA sequencing was performed to correlate specific nucleotides in ITS region of rDNA with the four genotypes and to define signature residues associated with resistance of *C. dubliniensis* isolates to 5-flucytosine.

Results: Majority (49 of 76, 64%) of *C. dubliniensis* isolates belonged to genotype 1, DNA sequences of ITS region of rDNA from 12 randomly selected isolates were identical and matched completely with the prototype strain CD36. A total of 21 isolates (21 of 76, 28%) yielded an amplicon with genotype 4 specific primers only and their ITS region sequences matched completely with the prototype strain of genotype 4. Only 1 isolate belonged to genotype 3. None of the *C. dubliniensis* strains belonged to genotype 2. Five isolates yielded amplicons with more than one genotype-specific primer pair and DNA sequences of the ITS region from these isolates identified them as hybrid strains. A total of 21 *C. dubliniensis* isolates were resistant to 5-flucytosine, all 21 belonged to genotype 4 and were characterised by the presence of a T residue at nucleotide position 82 in the ITS region.

Conclusions: Only three of four genotypes based on ITS region sequences were detected among clinical *C. dubliniensis* isolates in Kuwait with most (64%) of the isolates belonging to genotype 1. All *C. dubliniensis* isolates resistant to 5-flucytosine belonged to genotype 4 and were defined by a signature nucleotide in the ITS region of rDNA. The *C. dubliniensis* hybrid strains closely related to genotype 4 but not containing this signature nucleotide were not resistant to 5-flucytosine.

P727 Genotypic relatedness of *Candida* spp. in neonatal intensive care unit

K. Eimra, K. Truusalu, H. Järv, M. Ilmoja, H. Padari, I. Lutsar (Tartu, EE)

Objectives: We aimed to characterise the genetic relatedness of *Candida* species isolated from samples taken on clinical grounds in two NICUs in Estonia using pulsed field gel electroforesis (PFGE).

Methods: *Candida* spp. were isolated from August 2005 to May 2006 in unit A and from June 1999 to November 2005 in unit B and stored in sterile water or cryopreserved. The species were identified with CHROMagar *Candida*, Corn Meal Agar with Tween 80 and API *Candida*. The relatedness of the isolates was analysed by optimisation of previously described PFGE method as follows: BssHII digested DNA was electrophoresed with a voltage of 4V/cm, temperature 14 degrees C, linear ramped pulse times 5 to 50 seconds and run time of 20 hours.

Results: A total of 83 isolates (12 from blood, 57 from trachea and 14 from other sites) from 52 neonates were analysed. Of 16 invasive isolates *C. parapsilosis* (n = 8) and *C. albicans* (n = 6) were most commonly seen. *C. guilliermondii* (30%), *C. parapsilosis* (30%) and *C. albicans* (29%) were predominant isolates in colonised patients. In unit A all 6 *C. albicans* isolates were genotypically different whereas in unit B only 2 clones among 18 isolates were identified. Of 25 isolates of *C. guilliermondii* and *C. parapsilosis* each only 2 and 3 different clones, respectively, were seen. However, *Candida* strains isolated in 2000–01 differed from those obtained in 2005–06 by one or two bands suggesting that microevlolutionary changes within a strain had occurred.

Conclusion: Although *C. guillliermondii* was a frequent coloniser in the NICU patients, yet it was rarely associated with the invasive disease. The presence of a limited number of different clones of *C. guilliermondii* and *C. parapsilosis* indicates permanent source in the NICU and suggests for transmission by direct or indirect contact and cross-colonisation by healthcare workers.

P728 Establishing a rep-PCR DNA fingerprinting library for moulds

K. Reece, E. Atkins, T. Ross, S. Abedi, C. Smith, W. Dutch, M. Wise, J. Embry, S. Frye, M. Healy (Athens, US)

Objectives: Discrimination among moulds is often difficult. The advances in many areas in microbiology are limited when looking at moulds. Morphololgical characterisation and staining techniques are still very common. Sequencing and real-time PCR can be used

but additional technologies are needed for investigation of moulds. Previous studies have shown the promise for the use if rep-PCR DNA fingerprinting as a molecular method to characterise some moulds. This study reports the compilation of an expanded Mould database as an additional tool that can be applied to mould characterisation and subspecies discrimination.

Methods: A total of 250 previously characterised moulds (including strains from 30 Genus/species) obtained from environmental and clinical sites and ATCC reference strains were cultured. The isolates were extracted and then amplified using the Mold Kit for DNA fingerprinting. The amplified product was separated using a microfluidic based detection. The resulting data was analysed using dendrogram analysis and a Mould library was created using the DiversiLab Software. An additional 50 mould isolates were processed and compared to the library for validation.

Results: The resulting fingerprints from the first 250 characterised isolates grouped into multiple clusters. No different Genus/species showed the same fingerprint pattern. Some species had more than one fingerprint pattern, or cluster, indicating discrimination to the subspecies and/or strain level. Many of the 50 isolates used for validation showed matches to the library. Some isolates formed new clusters but no false positive groupings are seen.

Conclusions: These data suggest that a characterised library may prove useful to provide additional information or confirmation when using DNA fingerprinting for moulds. The DiversiLab System shows promise as a tool to aid in surveillance and identification of hospital acquired infections and epidemiological studies.

P729 Evaluation of differential expression of calnexin gene during transition from mycelial to the yeast infective of the fungus *Paracoccidioides brasiliensis* and localisation of native protein

L.S. Feitosa, W.L.. Batista, P. Xander, Z.P. Camargo (São Paulo, BR)

Introduction: *Paracoccidioides brasiliensis* is a dimorphic fungus responsible for paracoccidioidomycosis (PCM); man is infected by inhalation of conidia. The cellular differentiation of *P. brasiliensis* from mycelium (M) to yeast (Y) in the lungs is essential factor to establish the infection. Calnexin is a chaperone that recognises specifically monoglucosylated glycoproteins in the endoplasmic reticulum, being an essential component of the folding process of nascent secreted glycoproteins. Objective: Evaluation of differential expression of the PbCNX transcripts and analysis of cellular localisation of protein native.

Methods: RNA isolated from *P. brasiliensis* after heat shock and at different phases. The cDNA encoding PbCnx was cloned and overexpressed as recombinant protein in *Escherichia coli* and used to immunise rabbits in order to obtain anti-PbCnx serum.

Results: Expression of the PbCNX transcripts was investigated in total RNA isolated from *P. brasiliensis* after heat shock and at different phases of the mycelium to yeast (M-Y) transition or yeast and mycelium phases (Y and M), by real time RT-PCR. Our results suggest that there was an increased in PbCNX expression at 10 h after temperature change (25 to 36ºC), but normal levels was observed at the last point analysed (M-Y). Additionally, there was a 3.5-fold increase in transcription after heat shock at 42ºC for 60 min. Antibodies used in the reactions recognise specifically a single 70 kDa in the cell wall (alkaline-mercaptoethanol extract) component, compatible with the predicted size of the protein.

Conclusion: The evaluation of differential expression during transition from mycelial to the yeast infective of calnexin suggest that is a heat shock protein and is the first time that PbCnx has been observed on the cell surface, however, its function is speculative. Financial support: FAPESP and CNPq.

P730 Molecular karyotype of Sporothrix schenckii: analysis of chromosomal polymorphism among different isolates

L.S. Feitosa, A.A. Sasaki, Z.P. Camargo (São Paulo, BR)

Introduction: Classical genetic analysis of S. schenckii, aetiological agent of sporotrichosis, has been impaired by the absence of known teleomorphic stage. Experiments employing in vitro mutagenesis led to the selection of few mutants with stable phenotypes, since the number of revertants were high. The genetic composition of the fungus is poorly known and information about the genome size and chromosome organisation is scarce.

Objective: This study aims to provide a better characterisation of S. schenckii chromosomal polymorphisms among human clinical isolates (lymphocutaneous forms), and ambient sources.

Methods: Approximately 2X107 yeast cells were imbibed in low melting agarose. Spheroplasts were obtained by digestion of the cell walls with zymolmyase and disrupted in a solution containing EDTA, sarcozyl and proteinase K. Electrophoretic separation was performed under pulsed-field gel electrophoresis (PFGE) conditions.

Results: Differences in electrophoretic mobility of bands suggest the existence of chromosomal polymorphism and make it difficult to correlate the banding pattern among isolates. The analysis of our results shows 5 to 6 chromosomal bands and genome size about 28 Mb. Differences among the number of chromosomes and electrophoretic mobility of chromosomal bands were observed. New and distinct profiles emerged when comparing our data with previously described ones. The results also indicated that isolates from different geographical areas present quite similar banding patterns.

Conclusion: The results were consistent with a haploid number of 4–6 chromosomes. The haploid genome was estimated to be in the range of 28 Mb. The plasticity fungus genome could have implications for maintenance of genome functionality and for the control of gene expression.

Financial support: FAPESP and CNPq.

P731 Characterisation and expression of the gene encoding a gli-coprotein of 70 kda (gp70) from *Paracoccidioides brasiliensis*

J.T. Maricato, L.S. Feitosa, R. Puccia, G.H. Goldman, J.D. Lopes (São Paulo, Ribeirão Preto, BR)

Introduction and Objectives: *Paracoccidioides brasiliensis* is a thermodimorphic fungus that causes Paracocciodioidomycosis (PCM), human systemic granulomatous disease prevalent in Latin America. Most of the genes encoding and proteic sequences of relevant fungal antigens remain uncharacterised. *P. brasiliensis* produces some important antigens like gp43 which has been fully characterised, and a 70 kDa glycoprotein (gp70) recognised by 96% PCM patients'sera. It has been shown that this purified antigen modulates murine peritoneal macrophages functions and that passive immunisation of mice with specific anti-gp70 mAbs before fungal infection, significantly inhibited lung granuloma formation. The purpose of this work was molecular cloning and characterisation of the gene that encodes gp70 from *P. brasiliensis* followed by heterologous expression of the recombinant antigen to better understand the role of the gp70 in PCM.

Methods and Results: Using degenerated oligonucleotides corresponding to peptides obtained by microsequencing from gp70, recognised and isolated with specific mAB (C5F11), a 384-bp DNA fragment was amplified from the *P. brasiliensis* genomic DNA (pbgp70). This fragment showed 97% of similarity with one of the Expressed Sequence Tags (ESTs) in *P. brasiliensis* EST databank. Specifc oligonucleotides were synthesised attempting to obtain the sequence and amplifying the genomic and cDNA sequences corresponding to this EST. Using these specific oligonucleotides, 2.0 kb products were obtained by PCR of the genomic DNA and cDNA. These fragments were cloned and sequenced by primer walking. In preliminary sequence analysis it was found the open reading frame in a 1.6 kb fragment. Deduced amino acid sequence showed prevalence of hydrophilic regions which probably contains B-cell epitopes, one putative T-cell mouse epitope and high Jameson-Wolf Antigenic Index. BLAST analysis showed homology with putative proteins from the fungus *Coccidioides immitis*, *Aspergillus fumigatus*, *Ajellomyces capsulatus*, which are phylogenetically close to *P. brasiliensis*. Other oligonucleotides are being synthesised to achieve the heterologous expression of the cDNA sequence and subsequent obtention of the recombinant protein for further biological assays.

Conclusion: The 2.0 kb genomic DNA and cDNA cloned sequences presents some predicted characteristics of the *P. brasiliensis* native gp70 and may represent the gene of the gp70 antigen. Financial Support: CAPES

P732 Identification of *Paracoccidioides brasiliensis* highly virulent isolate ligands peptides by phage display with fungicidal activity in vitro

E.S. Kioshima, F. Aliperti, L.L. Villa, J.D. Lopes (São Paulo, BR)

Introduction: Paracoccidioidomycosis is a human systemic granulomatous disease, prevalent in South America, caused by a thermodimorphic fungus, *Paracoccidioides brasiliensis*. This fungus presents complex antigenic structure and some of these components have been related with its pathogenicity, of which little is known. Objective: To isolate molecules expressed in the surface of highly virulent but not in non-virulent isolated yeast cells of *P. brasiliensis* by phage display techonology, thus identifing possible virulence factors.
Methods: A phage display library containing the insert CX7C was screened to search high-virulent isolate of yeast cells of *P. brasiliensis* ligands by Biopanning and Rapid Analysis of Selective Interactive Ligands method. After three rounds of selection, the DNA corresponding to peptide inserts of randomly chosen phage clones were sequenced. Peptide sequences were then analysed according to their enrichment and by Clustal W sequence alignment. Selected motifs were used to search nonredundant protein databanks (National Center for Biotechnology Information [NCBI] BLAST.
Result: The B10.A mice were inoculated with yeasts of different isolates of *P. brasiliensis*. Animals that received non-virulent isolates Pb18 and Pb265 groups behaved as the control group which received only PBS, but the group that was infected with highly virulent isolate Pb18 died 90 days after injection. We identified three peptides (CGSYGFNAC, CGLRLESTC and CGLRLESTC) that bound to the surface of the high-virulent but did not or did less in non-virulent isolate of *P. brasiliensis* in all experimental conditions tested ($P < 0.01$). Other experiment showed that phage-cells binding was dose-dependent. By EIA assay with synthetic peptides, a significant binding of these peptides to gp43 (the majority molecule) was not observed. These peptides exhibited fungicidal activity in vitro against *P. brasiliensis* by inhibition of colony forming units.
Conclusion: The peptides CGSYGFNAC, CGLRLESTC and CGLRLESTC may represent ligands of molecules that can be involved in the virulence and pathogenicity of this fungus. Financial support: FAPESP.

P733 Genotyping of *Trichosporon asahii* strains isolated from urinary tract infections in a Turkish university hospital

Z.C. Karahan, E. Koyuncu, I. Dolapci, O. Arikan Akan, A. Tekeli (Ankara, TR)

Objectives: *Trichosporon* infections are associated with a wide spectrum of clinical manifestations ranging from superficial cutaneous involvement to severe systemic disease depending on the immune status of the patient. *Trichosporon asahii* appears to be the most important species in the genus. Invasive infections with *T. asahii* has been described most frequently in immunocompromised hosts, although some case reports of *T. asahii* infections in immuncompetent patients exist. In this study, we evaluated the genotypic relatedness of *T. asahii* strains isolated from non-immunocompromised patients' urinary tract infections.
Methods: A total of 25 *T. asahii* urinary strains were studied. The isolates were obtained from17 immuncompetent patients (11 male, 6 female, median age 44) hospitalised at different wards (neurosurgery, urology, nephrology, orthopaedics, reanimation) of Ankara University Ibn-i Sina Hospital between July 2004-April 2005. None of the patients were neutropenic during the period when *T. asahii* was isolated. *T. asahii* identification was made by using the API 20C AUX (BioMérieux Vitek, USA) and confirmed by PCR by using genus and species specific primers. Genotyping of *T. asahii* strains were made by RAPD and REP-PCR methods by using M13 and ERIC2 primers, respectively.
Results: All of the isolates gave amplicons by *Trichosporon* specific primers. When species specific PCR was performed, 23 of the isolates obtained from 15 patients gave amplicons. These 23 isolates were subjected to genotyping. RAPD analysis by M13 primer resulted in clustering of the isolates into 5 groups; four of the groups were composed of single isolate, and the fifth group contained 19 isolates. The results of REP-PCR analysis showed good corelations with the data obtained by RAPD method, although this method produced three different groups. Two of the groups contained single isolates which corresponded to the two groups of RAPD analysis. The third group consisted of 21 isolates containing the two isolates which were distributed to different groups by RAPD analysis.
Conclusion: Here we report 15 immuncompetent patients with urinary tract infections due to *Trichosporon asahii*. In this first study of invasive trichosporonosis from Turkey, 19 of the 23 isolates were found to be genotypically related, suggesting that a single genotype was prevalent in the hospital environment. The genotypically unrelated four isolates were probably of endogenous origin.

P734 Clinical performance of FXG^{TM} : RESP (Asp +) assay for aspergillus on respiratory specimens

C. Lass-Florl, J. Bille, D.S. Perlin, S. Park, K. Lagrou, E. Harrison, W. Meersseman, X. Cui, M. Hughes, D.W. Denning, J. Maertens (Innsbruck, AT; Lausanne, CH; Newark, US; Leuven, BE; Manchester, UK)

Objectives: Early diagnosis of invasive aspergillosis (IA) is essential to survival. Classical microbiological methods are slow and insensitive. Real-Time PCR offers the prospect of both faster and more sensitive microbiological confirmation of IA. FXG : RESP (Asp +) is a new test kit that detects both *Aspergillus* spp. and *Pneumocystis jirovecii*, utilising molecular beacons. This ready to use PCR assay consists of an extraction kit plus PCR assay and is CE marked. In this report we focus on the clinical performance for *Aspergillus* spp.
Methods: The FXG : RESP (Asp +) real-time PCR kit was tested on 198 respiratory specimens from a wide variety of patient groups, collected from 4 European hospitals. Analysis was carried out using an AB7500 thermocycler. Samples of BAL were mostly stored at –20 to –80ºC prior to DNA extraction using the MycXtra^{TM} fungal DNA extraction kit. Some sputum samples were also processed. The FXG : RESP (Asp +) results were compared with culture for *Aspergillus* spp. The whole assay time including extraction is <4 hours from BAL and <5 hours from sputum. The limit of detection was ~1 genome for *A. fumigatus* (as assessed by purified Af293 DNA), and this was used as the clinical cut-off. An internal amplification control reaction within the kit detects inhibitors that might affect the PCR reaction, although positive results in the presence of inhibition may be reported.
Results: Overall, for all 198 respiratory samples the sensitivity was 74% and specificity 93% with positive and negative predictive values 76% and 92% respectively. On 75 freshly collected sputum and other lower respiratory tract samples the sensitivity and specificity were 79% and 88% respectively. The FXG : RESP (Asp +) assay also detects *Penicillium* spp. as the target sequence in this fungus is identical. 3 samples were culture positive for *Penicillium* spp., and positive for FXG : RESP (Asp +) and recorded as 'false positives'. The FXG : RESP (Asp +) does not detect Zygomycetes or *Candida* spp., and this was confirmed in the clinical study.
Conclusions: Overall the speed of detection and sensitivity of the FXG : RESP (Asp +) assay will bring considerable clinical benefits. Additional prospective and supportive clinical trials are ongoing.

P735 **Identification of the pre-mRNA splicing protein U2AF35 in the opportunistic fungus *Pneumocystis carinii***

C. Thomas, B. Sanyal, P. Vohra (Rochester, US)

The opportunistic fungus *Pneumocystis carinii* (PC) is an intractable organism responsible for severe pneumonia in patients with AIDS or other immunosuppressive conditions. PC is phylogenetically similar to the non-pathogenic yeasts *S. cerevisiae* and *S. pombe*. The regulation of gene function is a complex process critical to the survival of eukaryotes, and thus presents potential targets for novel therapy. Pre-mRNA processing with removal of intervening sequences (introns) is an important step in gene regulation. The assembly of multiple proteins on small nuclear RNA occurs in the spliceosome. Although many components of this molecular machinery is conserved in eukaryotes, there are many significant differences between *S. cerevisiae*, *S. pombe* and mammals. The process of gene regulation in PC is unknown. We have previously reported that PC genes contain multiple small introns, yet lack features found in *S. cerevisiae* and *S. pombe* (Infection and Immunity, Nov. 1999, p. 6157–6160). Here we report the identification and cloning of the PCU2AF35 gene, encoding a critical splicosomal protein required for processing the 3′ end of the intron. PCU2AF35 is a 621-bp ORF encoding a predicted 206 amino acid protein. The predicted molecular weight is 24.1 kDa, similar to *S. pombe* U2AF35. PCU2AF35 contains a conserved RNA recognition motif (RRM) postulated to bind RNA sequences. PCU2AF35 is most homologous to *S. pombe* U2AF35 (72% identity). We have expressed this gene as a recombinant protein to determine its function in PC intron removal. Our investigations may provide new insights into the pathogenesis of PC and potential new therapeutics for treating PC pneumonia through identification of mechanisms involved in PC life cycle regulation.

P736 **Rapid identification and differentiation of Trichophyton species, based on sequence polymorphisms of the ribosomal internal transcribed spacer regions, using rolling circle amplification**

F. Kong, Z. Tong, X. Chen, T. Sorrell, B. Wang, Q. Wu, D. Ellis, S. Chen (Sydney, Adelaide, AU; Beijing, CN)

Objectives: To develop a novel padlock probe and rolling circle amplification (RCA)-based method, for identification of single nucleotide polymorphisms (SNPs) to differentiate between major members of the genus Trichophyton.
Methods: The ITS region (ITS1, 5.8S and ITS2) of 42 dermatophytes belonging to seven species (Trichophyton rubrum, T. mentagrophytes, T. soudanense, T. tonsurans, Epidermophyton floccosum, Microsporum canis and M. gypseum) were sequenced. Polymorphisms were identified after multiple sequence alignment and comparison with relevant archived GenBank sequences. Either species-specific or group-specific padlock probes were designed to detect the species above.
Results: DNA sequencing demonstrated demonstrated intra-species genetic variation for T. tonsurans, T. mentagrophytes and T. soudanense, but not for T. rubrum. Signature sets of SNPs between T. rubrum and T. soudanense (4 bp difference), and T. violaceum and T. soudanense (3 bp difference) were identified. The RCA assay correctly identified five Trichophyton species. Although use of two "group-specific" probes targeting both the ITS1 and ITS2 regions were required to identify T. soudanense, the other species were identified by single ITS1-, or ITS2-targeted species-specific probes. There was good agreement between ITS sequencing and RCA assay.
Conclusion: Despite limited ITS sequence-based variation between Trichophyton spp., the RCA-based SNP detection assay showed potential as a simple, specific and reproducible method for rapid (2 hours) identification of Trichophyton spp.

P737 **Genotypes of human *Blastocystis hominis* isolates and its pathophysiological varaibility in exeperimentally infected rats**

E.M. Hussein, A.M. Hussein, M.M. Eida, M.M. Atwa (Ismailia, Cairo, EG)

Background: A definite correlation between the distinct genetic variability present in *Blastocystis hominis* parasite and its pathogenecity has not yet been confirmed.
Objectives and Methods: The first objective of this study was identify the genotypes of *B. hominis* clinical isolates obtained from 28 gastrointestinal symptomatic patients and 16 asymptomatic individuals by PCR using sequenced-tagged site (STS) primers. The second objective was evaluation the pathophysiological variability between different *B. hominis* genotypes induced in experimentally infected rats by identify the histopathological changes, the mortality rate and the intestinal cell permeability in Ussing chamber. Infected rats with asymptomatic and symptomatic human isolates were used.
Results: Only 4 *B. hominis* genotypes were identified among all the human clinical isolates. Subtypes 1, 2, 3 and 4 were detected among 18.2%, 9.1%, 54.5% and 18.2% of the human isolates. In symptomatic isolates subtypes 1, 3 and 4 were detected in 28.6%, 57.1% and 14.3% respectively. In asymptomatic isolates subtypes 2, 3 and 4 were identified in 25%, 50%, and 25% respectively. Subtype 3 was the commonest among humans. Different degrees of pathological changes were found among infected rats by symptomatic subtypes as compared with asymptomatic subtypes. The moderate and severe degrees of pathological changes were found only in symptomatic subtypes infected rats while mild degree was found only in asymptomatic subtypes infected rats. No extra intestinal lesions were found. Only subtype1 induced mortality rate with 25% among infected rats. On evaluation of the intestinal cell permeability, a prominent increasing in short circuit current (ÄIsc) was found in symptomatic subtypes 1 compared to symptomatic subtypes 3 and 4 infected rats. Meanwhile, minimal effects were found in asymptomatic and control groups.
Conclusions: Subtype 1 is relevant to the pathogenecity of *B. hominis* while, subtype 2 is irrelevant. The presence of subtypes 3 and 4 among symptomatic and asymptomatic isolates suggested that the variability on Blastocystis pathogenecity among these subtypes may be related to the presence of sub-strains (pathogenic or non-pathogenic) which needs further studies.

Amoeba

P738 **Real-time PCR as a semi-quantitative alternative for microscopic detection of *Dientamoeba fragilis***

T.J. van Middelkoop, B.A. Poell, L. Mulder, J.J. Verweij (Enschede, Leiden, NL)

Objectives: Since the discovery of *Dientamoeba fragilis*, the pathogenicity of this organism has remained controversial. Microscopic detection did not imply a quantification of this frequently found faecal parasite. A new real-time PCR based on the 5.8S ribosomal RNA gene was developed for the detection of *D. fragilis* in faecal samples. We examined if this could provide a semi-quantitative alternative for microscopic detection.
Methods: Microscopic examination was carried out on IHK stained faecal samples collected after SAF fixation with the Triple Faeces Test (TFT). A selection of 200 positive and 200 negative samples was made. Real-time PCR was performed on the corresponding fresh stool samples. The PCR also included an internal control (PhHV) to detect inhibition of the amplification by faecal constituents in the sample.
Results: In the first half year of 2007, 2052 faecal samples were examined of which 394 were positive for *D. fragilis* (19.2%). In the selection of 400 samples no inhibition of amplification was found. In 200 microscopically negative stool samples *D. fragilis* was amplified in 12 cases. In these 12 samples, the presence of *D. fragilis* could be confirmed microscopically after re-analyses of the permanent staining

preparations in 9 cases, corresponding to a specificity of 98.5%. In a selected group of 200 faecal samples from patients in which one or two preserved samples showed *D. fragilis* trophozoites, *D. fragilis*-specific amplification was detected in 184 DNA samples wich corresponds to a sensitivity of 92%. The mean Cp value of the positive samples was 30.7 with a range from 20.1 to 37.8.

Conclusions: The real-time PCR for the detection of *D. fragilis* achieved 98.5% specificity and 92% sensitivity. The use of this assay in a diagnostic laboratory offers the possibility of introducing DNA detection as a feasible technique for the routine diagnosis of intestinal *D. fragilis* infections and provides a reliable semi-quantitative measure for further pathogenicity studies.

P739 Molecular assays to diagnose *Entamoeba histolytica* and *E. dispar* infections in a non-endemic area (Parma, Italy)

A. Calderaro, C. Gorrini, S. Peruzzi, G. Piccolo, G. Dettori, C. Chezzi (Parma, IT)

Objectives: The detection of *Entamoeba histolytica* (Eh), causative agent of amoebiasis, is an important goal of the clinical parasitology laboratory. The identification of *E. dispar* (Ed) as a morphologically identical but non-pathogenic species has highlighted the need for non-microscopic detection methods able to differentiate the 2 species. Moreover, a reassessment of the worldwide prevalence of amoebic infection based on discriminatory methods has been strongly recommended by WHO.

The area in which our laboratory is located has seen in recent years an increase of people travelling through and a significant flow of immigration from tropical countries which has led to a parallel increase in imported infections.

Thus, the aim of this study was to promptly diagnose and discriminate Eh and Ed infections and to assess their occurrence among patients with suspected intestinal parasitosis presenting to the University Hospital of Parma.

Methods: The specimens analysed in this study were selected from the whole of the clinical samples sent to our laboratory with the suspicion of intestinal parasitosis during 2003–2007 and subjected to standard procedures (microscopic examination) for the detection of intestinal parasites. In particular, 730 samples (715 faeces, 7 liver abscess samples, 8 intestinal biopsies) belonging to 407 patients were analysed. The samples were subjected to culture for intestinal protozoa and molecular assays (conventional or Real-Time PCR) able to distinguish Eh from Ed DNA.

Results: Eight patients (1.96%) proved to be infected by Eh (3 with extraintestinal and 5 with intestinal amoebiasis; 5 with imported amoebiasis and 3 with the disease acquired in Italy) and 36 by Ed (8.84%). In particular, in 4 of the 8 patients with Eh infection, only molecular methods were able to detect the presence of the parasite.

Conclusion: Our results underline that traditional methods underestimate the prevalence of amoebic infection and highlight the important diagnostic role that PCR can play. Species differentiation by PCR becomes an important tool for clinicians as it permits them to focus on Eh infections and to avoid treatment when non-pathogenic Ed is present. The relatively high prevalence of Ed infections observed in this study versus the more rare Eh infections, is indicative of the existence in the community of a faecal-oral route of agents with an exclusively inter-human circulation and calls for the activation of adequate control measures.

P740 Amoebic keratitis in Iran (1997–2007)

M. Rezaeian, S. Farnia, M. Niyyati, F. Rahimi (Tehran, IR)

Objective: Amoebic keratitis introduced as a painful corneal infection which sometimes lead to poor vision and blindness. The main goal of this study was to report amoebic keratitis during ten years from 1376–1386 in patients who was suspected to amoebic keratitis and referred to parasitology laboratory, School of Public Health, Tehran Medical University, Iran. Other aim was to assess the major risk factor for developing this sight-threatening disease. Comparison of lens culture and corneal scrapes culture also performed.

Methods: During 1376–1386, 142 patients referred to department of parasitology, School of Public Health, Tehran Medical University. Details of each patient such as age, sex, history of contact lens wear, type of contact lens, clinical symptoms were record in questioners. Keratitis was diagnosed on the basis of culture of lenses and/or corneal scrapes on non-nutrient agar overlaid with *Escherichia coli* and direct microscopy of lenses and/or corneal scrapes.

Results: Among 142 patient who referred to department of parasitology, School of public health, Tehran Medical University, Iran, 49 patients (34.5%) had Amoebic keratitis. 73.46% of these patients were from Tehran but there were a few cases from other cities. The commonest age was between 15–25 (75.5%) and more female (37:12) were identified then male. It is worth to mention that 44 patients (89.79%) were contact lens wearers which among them 41 patients (93.18%) wore soft contact lens and only three patients suffer from amebic keratitis because of wearing hard contact lens. Other finding of this study demonstrated that the most common sign of the patients was severe pain combined with photophobia.

Conclusion: This study indicate that Acanthamoeba keratitis continue to rise in Iran. This is due to increase frequency of lens wearers as well as consideration of ophthalmologist to Acanthamoeba as an agent of keratitis and improvement of laboratory methods. Another finding of this research was the confirmation of soft contact lens as a major risk factor. It is recommended to educate contact lens wearers for regular disinfection. Besides, culture of corneal scrapes was negative in most of cases, so lens culture were performed which had a much better result.

P741 Diagnosis of dientamoebiasis: efficacy of culture and comparison of three culture media

Ö. Kurt, I. Östan, N. Girginkardesler, Ü.Z. Ok, A. Özbilgin (Manisa, TR)

Objectives: The diagnosis of dientamoebiasis depends on the demonstration of *Dientamoeba fragilis*, a common but rarely identified intestinal protozoon. Its nuclear structure can only be seen with permanent stains, such as trichrome or iron hematoxylin; therefore, examination of permanent stained smears of fresh or fixed stool samples by an experienced microscopist is obligatory for the diagnosis of dientamoebiasis. Culture is known to be a more sensitive method but it is out of scope of many laboratories in routine diagnosis. However, it may identify the overlooked cases with microscopy and is reported to be less laborious than trichrome staining. Our aim was both to assess the efficacy of culture and compare the efficacies of three culture media, Robinson's, Dobell's and Talis's diphasic egg medium (TDEM) in the diagnosis of dientamoebiasis.

Methods: Among the 93 dientamoebiasis patients diagnosed in the Parasitology Laboratory of Celal Bayar University Hospital, stool samples of 80 and 75 patients were inoculated in Robinson's and Dobell's media, respectively, while 65 were inoculated in TDEM; stool samples of 61 patients were inoculated in all three media. In addition, stool samples of 160 Dientamoeba-negative individuals diagnosed with the microscopic examination of trichrome stained smears were inoculated in all three media. All culture tubes were checked by the microscopic examination of a drop of sediment at 48, 72 and 96 hours after inoculation. The sensitivity and specificity values of Dobell's medium and TDEM were assessed compared to Robinson's medium.

Results: Diagnostic efficacies of each medium were found to be 90%, 76% and 86% for Robinson's, Dobell's and TDEM, respectively. Among the 160 microscopically-negative samples, the growth of *D. fragilis* was detected in 17 (11%), 5 (3%) and 6 (4%) in Robinson's, Dobell's and TDEM, respectively. All positive samples in Dobell's medium and TDEM were also found to be positive in Robinson's medium.

Conclusion: Our results suggest that microscopy may overlook significant number of dientamoebiasis cases, which are detectable with culture, and Robinson's medium may be used effectively even in routine diagnosis of dientamoebiasis, instead of trichrome staining. Culture is by far less expensive than molecular methods and may be preferred where

novel diagnostic methods, such as PCR, are not available due to their higher costs, especially in developing countries.

P742 Detection of amebiasis among men who have sex with men, with or without human immunodeficiency virus infection

C.C. Hung, N.Y. Ko, P.Y. Wu, C.H. Wu, W.C. Liu, H.Y. Sun, S.C. Chang (Taipei, Tainan, TW)

Objectives: Men who have sex with men (MSM), regardless of HIV status, are at increased risk for amebiasis because of oral-anal sexual contact in Taiwan. In this study, we aimed to evaluate the association of seroconversion for *Entamoeba histolytica* infection with newly acquired intestinal infection with *E. histolytica* among MSM.
Methods: Between 1 January, 2007 and 30 November, 2007, 143 MSM (128 HIV-infected) who were free of gastrointestinal symptoms provided both blood and stool specimens for serological tests and specific amebic antigen tests for *E. histolytica* infection, respectively. Anti-*E. histolytica* antibodies were determined using indirect hemagglutination (IHA) assay (Cellognostics, Boehhringer Diagnostics GmbH, Marburg, Germany), while stool amebic antigen was determined using commercial test kits (ENTAMOEBA TEST, TechLab, Branchburg, NJ) followed by polymerase chain reactions (PCR) using specific primers for *E. histolytica*.
Results: In this survey, the prevalence of intestinal E. histolytca infection was 9.1% (13/143) and the seroprevalence of *E. histolytica* infection (IHA titers $\leqslant$32) was 17.5% (25/143) among the subjects. MSM who were seropositive were at statistically significantly higher risk for intestinal *E. histolytica* infection with an odds ratio of 25.56 (95% confidence interval, 6.316, 103.4) ($p<0.0001$).
Conclusion: We found that MSM who were IHA-seropositive for E. histolytcia was more likely to present with intestinal *E. histolytica* infection than those who were seronegative. In clinical settings where amebiasis is suspected and stool samples may not be readily available, serologies for *E. histolytica* is a cost-effective screening alternative to identify *E. histolytica* infection among MSM.

P743 Indigenous amebiasis in hypoendemic area: myth or reality?

M. Ivanova, M. Nedzvedz, S. Poljakova, E. Saridze, S. Fedorovich, E. Glod (Minsk, BY)

Amebiasis is one of the three most common causes of death from parasitic disease. Belarus is considered a non-endemic country since indigenous transmission of the *Entamoeba histolytica* parasite may be virtually non-existent. However, invasive intestinal and extra-intestinal infections have also been found among Belarusian population.
Objectives and Methods: The medical records of in-patients, who had been diagnosed as cases of amebiasis, at some hospitals in Minsk in 1994–2006, were retrospectively reviewed. This grope consist of 24 patients, 13 females and 11 males, average patient age was 56.4 years (range 22–81 years). To avoid overdiagnosis in each case, amebiasis was confirmed by the identification of hematophagous trophozoites of *Entamoeba histolytica* by microscopic examination of stool, pus and tissue intravital and postmortem. Unfortunately, this is the only test available in Belarus now. According to outcomes of disease there were 16 dead patients and 8 recovered ones.
Results: The epidemic investigation shows that only 2 patients have visited endemic amebic countries. All fatal cases were misdiagnosed, before the deaths following clinical diagnoses were made: liver abscess, acute gangrenous cholecystitis (2), tumour of brain, Crohn's disease (2), intestinal tuberculosis, pulmonary tuberculosis, cancer of colon (4), mesenteric thrombosis, acute anaemia, sepsis (2). Pathologic investigations reveal various amebic intestinal damages: terminal enteritis (1), ascendant colitis (1), sigmoiditis (4), total colitis (3); extraintestinal damages: liver (7), gall bladder (3), pancreas (1), lungs (2), brain (3). All of patients were burdened of premorbid conditions (diabetes mellitus, cancer, chronic diseases of lungs, GIT, heart).
In the group of survived patients, there were 6 cases of liver amebic abscess, 1 case of complicated amebic sigmoiditis and 1 case of amebic colitis with ulcerative colitis.
Conclusions: Amebiasis can be indigenous in the former hypoendemic countries and can has very severe fatal forms. It is necessary to improve clinical diagnostic and parasitological methods, to perform an antigen detection using ELISA to provide a more reliable comment on the epidemiological pattern and clinical impact of the disease.

P744 Prevalence of Entamoebae infection in Sudan

A. Saeed, H. Abd, G. Sandstrom, B. Evengard (Stockholm, SE)

Objective: The frequency of *E. histolytica* and *E. dispar* was studied and sociodemographic conditions associated with *E. histolytica* and *E. dispar* infection. A descriptive study was carry out in urban area of Khartoum the capital city of Sudan.
Methods: Stools samples were examined by microscopy and positive to *Entamoeba* were analysed by PCR to differentiate between *E. histolytica* and *E. dispar*.
Results: *E. histolytica* was detected in 106/196 (54.1%) and *E. dispar* in 100/196 (51%). The age groups most infected were >30 years old followed by <9 years old. *E. histolytica* was significantly associated with diarrhoea 103/196 (52.6%) and with the presence of Red blood cells in the stools 101/196 (51.5%).
Conclusion: *E. histolytica* and *E. dispar* infections are common in Khartoum, therefore we need to apply a technique help in differentiation between them in the routine diagnosis of the samples.

Malaria

P745 Comparison of three methods of real-time PCR with blood smears and antigen detection in plasmodial infection

N. Bourgeois, A. Boutet, D. Basset, P.J. Bousquet, M.J. Carles, S. Charachon, L. Lachaud (Nimes, Montpellier, FR)

Objectives: In malaria, rapid and accurate diagnosis of *Plasmodium* spp. is needed for adequate and efficient treatment. Three different rapid PCR methods were compared to the routine diagnosis method.
Methods: A transversal study was conduced in our laboratories located at Montpellier and Nîmes University Hospital. Routine method associated microscopy examination of Giemsa-stained blood smears and antigen detection by Now® Malaria kit. For control samples, antigens were not routinely searched when positive diagnosis was already obtained. DNA was extracted from the previous blood samples. The three methods of real-time PCR were optimised, and the SYBR Green was used for fluorescence detection in a LightCyclerTm instrument. The PCR1 amplified a specific sequence on the *P. falciparum* Cox1 gene. The PCR2 amplified a species-specific region of the multicopy 18S rRNA present in the four plasmodium sp that infect humans. Species differentiation was obtained by melting curve analysis. The PCR3 amplified a mitochondrial DNA sequence that allowed the differentiation of *P. falciparum* from the three others species.
PCR methods were compared between each other and with the routine method. Kappa and McNemar tests were performed.
Results: On the 245 blood samples (195 diagnosis and 50 controls) collected between 2005 and 2007, 118 samples were positive for at least one of the five methods (72 [36.9%] at diagnosis, and 46 [92%] at control).
Compared to the routine method, there was no false negative, neither in PCR1 nor in PCR3 for *P. falciparum* diagnosis. It is noteworthy that microscopy alone was negative in five samples, three of them also negative in PCR2. In all *P. ovale*, *vivax* and *malariae* infections, PCR1 was negative, as expected, whereas PCR2 and PCR3 were positive and concordant (simple Kappa coefficient = 1). Globally, for first biological diagnosis, PCR3 alone (n = 103) and the association of PCR1 and 2 (n = 195) were fully concordant with routine method. As regards control samples, the three PCR methods remained more often positive than blood smears (92% vs 34%) and this for a longer period after treatment.
Conclusion: Those three rapid PCR methods showed excellent results, used solely or in association. Nevertheless, PCR did not detect additional cases of malaria potentially undiagnosed by routine testing.

P746 Epidemiology of imported malaria to Catalonia (Spain): 2001–2006

M. Quesada, N. Cardenosa, J.P. Millet, L. Acosta, M. Oviedo, J.A. Caylà, R. García, E. Rodríguez, L. Sánchez, Á. Domínguez (Barcelona, Murcia, Madrid, ES)

Objective: To describe the epidemiology of malaria imported to Catalonia in six years (2001–2006).

Methods: In this retrospective study, we investigated malaria using data provided by database reports of illness of obligatory declaration from 2001 to 2006. Epidemiological data were analysed by age, sex, country of origin, country and date of trip, reason of travel, chemoprophylaxis, type of malaria, specie of plasmodium, treatment, length of hospital stay and outcome.

Results: During the study period, 1000 cases were notified in Catalonia, 94% (944) laboratory confirmed. Missing information or indeterminate results affected all variables. Almost all malaria cases (99.8%, 936) were imported: 87.6% (784) from Africa, 8.7% (78) from Central and South America, 3.6% (32) from Asia and 0.1% (1) from Oceania, by 24% (192) Spanish citizens and 76% (623) immigrants. Forty-nine percent of cases (441) were imported from Western Africa. In 80% (674) of patients *P. falciparum* aetiology, 14% (120) *P. vivax*, 4% (32) *P. ovale* and 2% (15) *P. malariae* were confirmed. Among the subjects, 60% (600) were men. The youngest patient was 5 months and the oldest 92 years old, 52% of patients (522) were in the age group 21 to 40 years old. Most common reasons for travel were individual travel 43% (254), tourism 37% (219) and professional or missionary travel 17% (102). In 25% (210) cases some kind of chemoprophylaxis was documented, but only 29% (60) specified which drugs were taken and only 10% (21) of cases did it correctly. Chemoprophylaxis consisted in mefloquine in 57% (85) of cases, chloroquine phosphate in 12% (18) and doxicicline in 7% (10). Fifty-nine percent (533) of patients required hospitalisation and 16% (75) of them stayed at the hospital more than 7 days. Four cases of malaria death were reported, all of them due to *P. falciparum* infection. These patients were Spanish adults that travelled to African countries and did not take chemoprophylaxis. Two hundred three children living in Catalonia and travelling to their parents' endemic country of origin became infected by *Plasmodium* spp., 55% (111) of them did not take antimalarial drugs.

Conclusions: During the period 2001–2006 in Catalonia *P. falciparum* was the main aetiology. Western Africa is the region and the continent from which most cases are imported. Immigrants contribute with most of cases. Children and Spanish adults deserve special attention because they often do not take preventive measures.

P747 Pyrosequencing for *Plasmodium falciparum* resistance in returning travellers, refugees and immigrants to Alberta, Canada

S. Shokoples, S. Yanow (Edmonton, CA)

Objectives: Travelers to malaria endemic areas, refugees and immigrants infected with malaria can provide information on the resistance patterns of circulating parasite strains. In 2007 we received 13 blood samples from 8 patients with *Plasmodium falciparum* malaria. These samples were tested for malaria and speciated by real-time PCR. Samples that were positive for *P. falciparum* were genotyped at the pfdhfr locus by pyrosequencing. In this study, we have examined three single nucleotide polymorphisms (N51I, C59R, and S108N/T) associated with resistance to the antimalarial sulfadoxine-pyrimethamine (SP).

Methods: DNA was extracted from 40 microlitres of whole blood using the PSS Bio Instruments 12GC or the Qiagen QIAamp Blood Mini Kit. Real-time PCR was carried out as described (Rougemont et al., 2004) with some modifications. Primers used for pyrosequencing were modified from those designed by Zhou et al. (2006).

Results: All of the malaria strains tested showed at least one mutation in the pfdhfr locus; the majority of the strains showed mutations in all three codons. One traveler to Papua New Guinea had been infected with parasites carrying two mutations in the pfdhfr locus: 59R, and 108N, consistent with high levels of resistance to SP in this area. Sibling refugees from Sierra Leone harbored parasites with the triple mutations 51I, 59R, and 108N. Both developed symptomatic malaria upon arrival in Canada. These genotypes correlate with high SP failure rates documented for Sierra Leone (Checci et al., 2005).

Conclusion: Molecular surveillance of *P. falciparum* in returning travelers, refugees and immigrants can contribute valuable genotyping data to global sentinel networks on the prevalence of drug resistant strains in those regions. Future work will include developing pyrosequencing protocols for other mutations associated with drug resistance, including pfATPase6 and pfcytb.

P748 Chloroquine susceptibility phenotype and virulence of *Plasmodium falciparum*

G. Saliba, W. Kamouh, A. Fontanet, J. Lebras (Paris, FR)

Objective: In order to study the relation between *Plasmodium falciparum*'s virulence and phenotype, Chloroquine® resistant or susceptible, we postulated, based on the Fitness concept, that the susceptible phenotype would be more virulent in-vivo than the resistant one and thus more predictive of severe malarial episodes.

Methods: A case-control study on severe malaria imported into metropolitan France over the period of January 1st 1996 and September 30th 2006. Cases and controls were defined as subjects manifesting severe and non severe malarial episodes respectively.

The world health organisation classification, 2000, was used to assess the severity of malarial episodes. The criterion of >4% of peripheral parasitism in non-immune patients was excluded among the above criteria. All patients fulfilling this condition, solely, were regarded as manifesting non severe malaria. Using a bilateral 80% statistically powered test to detect a minimum odds ratio (OR) of 2.0, the number of subjects required was estimated to be 91 severe and 364 non severe cases. Independent risk factors of severe malaria, and subsequently virulence assessment of *Plasmodium falciparum*'s phenotypes, were determined using multiple logistic regression models.

Results: Our study population consisted of 81 severe and 840 non severe cases. The threshold of 80% statistical power required for an appropriate analysis was respected by recruiting 921 subjects thus increasing the case-control ratio to ~1/10. Regarding severe falciparum malaria, the Chloroquine® susceptible phenotype turned to be a protective factor compared to the Chloroquine® resistant phenotype. After controlling for age, level of parasitism, continent of infection and native zone, the resistant phenotype was significantly associated with an increased risk of severe malaria with an OR of 1.85 (95% CI: 1.09–3.1). This result was controlled and consistently confirmed in several logistic regression models including and excluding missing data.

Conclusion: Virulence and Fitness do not seem to correlate. The adaptive advantage of the Chloroquine® susceptible phenotype, according to the Fitness concept, does not result in more enhanced in-vivo virulence. This is the first study to address this subject without any restrictions of age or of aetiology of severe malaria.

P749 High proportion of microscopically confirmed highlands malaria in Eldoret, Kenya (2450 metres)

L. Gabrhelova, Z. Nagyova, A. Kolenova, K. Moses, E. Kalavsky, N. Jalili, A. Kalavska, V. Krcmery (Trnava, Bratislava, SK)

Introduction: Malaria is a serious public health problem with social and economic consequences in sub-Saharan Africa in altitude under 1500–2000 m. Despite of altitude higher than 2000 m, cases of non-imported malaria were observed sporadically in 1990 as "highlands malaria". The reason why malaria is ascending to higher altitudes is global warming, agricultural and hydrological changes in combination with other causes.

Methods: We investigated the proportion of confirmed malaria cases among suspected non-imported malaria cases in a community health

centre in Eldoret, Kenya. Within 12 months (6/2005–5/2006) 16484 patients in OPD were seen.
Results: In 4985 patients (30%) malaria was clinically suspected and microscopic investigation of blood smear with direct microscopy and Giemsa staining of peripheral blood was performed. Of 4985 suspected cases, 1939 (39%) were positive. All patients received ACT (artemisine combination therapy) – CoArtem (Artesunate/Lumefantrine), no death on malaria was observed and loss of follow up was common. Also no single case of cerebral malaria was noticed. Cure rates were up to 99% when practically all patients responded to initially therapy.
Conclusion: "Highlands malaria" is a daily reality and up to 2000 (12%) cases a year among more than 16000 patients visits is seen even in altitude about 2500 m.

P750 Usefulness of polymerase chain reaction in the diagnosis of asymptomatic *Plasmodium* infection

A. Rodríguez-Guardado, F. Pérez, J. Ordás, J. Fernández, A. Perez, J.A. Cartón (Oviedo, ES)

Background: In malaria-endemic countries with stable transmission of malaria, semi-immunity is usually acquired after childhood. Infected adults have either uncomplicated malaria or asymptomatic parasitaemia. This fact is frequent in immigrant population
Methods: During the period of one year we screened 117 immigrants to investigate the presence of asymptomatic malaria. In all patients we realised microscopic examination of thin and thick blood smears, determination of plasmodium antigen (BINAX NOW®) and nested-PCR.
Results: During the period of the study we diagnosed 5 cases of asymptomatic malaria in five patients (4 women, one man). The other techniques were negatives. The countries of precedence were: Equatorial Guinea (two cases), Senegal, Brazil and Ivory Coast (one case respectively). The mean of stay in Spain was 852 days (limits 123–1825). No patients come back to native countries in this time. In three cases the nested-PCR was positive to *Plasmodium falciparum* and in two cases *Plasmodium malariae*. No patients showed symptoms or analytic disturbance. All patients were treated with quinine and doxycicline. No patients dead. After the treatment the PCR became negative in all patients.
Conclusions: Asymptomatic *Plasmodium* spp. parasitaemia in immigrants proceedings of malaria-endemic country is frequent. PCR appears to be a useful method for detecting asymptomatic malaria or low parasitaemias in immigrant patients. This fact is very important in detection and management of imported malaria.

P751 Can non-specific biochemical tests improve the diagnosis and contribute to prognosis in imported malaria?

J. Poluga, G. Stevanovic, M. Pelemis, J. Nikolic, M. Pavlovic (Belgrade, RS)

Objectives: The objective of this study was to evaluate role of nonspecific biochemical tests in malaria diagnosis, according to their sensitivity, specificity and positive predictive values. In addition, comparison with parasitaemia, occurence of complications, recovery duration and organ failiure was examined to determine possible prognostic value of routine biochemical parameters.
Methods: A retrospective study included 64 patients, diagnosed and treated for malaria in Institute for Infectious and tropical diseases KCS, from January 1999. to December 2006. and healthy control group (n = 11).
Results: Thrombocytopenia, leukopenia, hyperglycaemia, hypocholesterolaemia and elevation of transaminases, lactate dehydrogenase (LDH) and creatinine were associated with malaria. Although thrombocytopenia had highest sensitivity (84%), hyperglycaemia, leukopenia and hyperbilirubinaemia were the most specific (100%) and with the strongest positive predicitive values (100%). Malaria complications were associated with anaemia, leukopenia, thrombocytopenia, hypoproteinaemia, hyponatraemia and elevation of LDH and creatinine. Hypocholesterolaemia, anaemia and fibrinogen elevation had a significant effect on recovery duration. Hepatosplenomegaly in malaria was associated with thrombocytopenia and LDH elevation, as jaundice was associated with anaemia.
Conclusion: Nonspecific laboratory test are useful for prompt and accessible orientation and avoidance of misdiagnosis in febrille travellers returning from endemic regions. Furthermore they proved as valuable auxiliary diagnostic and prognostic tools in combination with the microscopic detection of parasites.

P752 Estimating parasitaemia of *Plasmodium falciparum*: UKNEQAS experience

M. Manser, C. Olufsen, P. Chiodini (London, UK)

Objectives: Approximately 10 percent of the malaria cases from the United Kingdom are seen at the Hospital for Tropical Diseases. The remainder of cases are widely distributed throughout the UK, thus any haematologist can be called upon to diagnose malaria in their laboratory. UKNEQAS Blood Parasitology Scheme was established in 1986, part of its remit was to assess the accuracy of the estimation of malaria parasitaemia the UK. Participants in this EQA scheme are required to identify blood parasites present in either thick or thin films and to estimate the percentage parasitaemia of *Plasmodium falciparum* if appropriate.
Methods: Eight distributions each containing one Geimsa stained thin blood film and/or a Field's stained thick film are dispatched annually to 300 laboratories in both UK and overseas to examine for blood parasites. Participants are expected to estimate the percentage parasitaemia, in the blood films containing trophozoites of *Plasmodium falciparum*, by expressing the number of infected cells as a percentage of the red blood cells.
Results: Results of participants' performance for the diagnosing and estimation of the percentage parasitaemia of *Plasmodium falciparum* were analysed over a fifteen year period. It was noted that between 16 and 58 percent of participants failed to estimate the percentage parasitaemia, between 7 and 28 percent overestimate it, between 2 and 10 percent underestimate and between 1 and 7 percent misidentified the malaria species present. It was also noted that the higher the parasitaemia, the more likely it was to be overestimated.
Conclusion: Although the analyses of results achieved by participants for other blood parasites has shown an overall improvement, estimation of the percentage parasitaemia of *Plasmodium falciparum* remains unchanged. One reason for this is the failure of many participants to specify the percentage parasitaemia. Of those that overestimate the parasitaemia, it is assumed to be due to counting the number of trophozoites per 100 red blood cells and not the number of parasitised red blood cells.

P753 Polymorphism of merozoite surface protein-3α gene of *Plasmodium vivax* in isolates in Iran

A. Raeisi, A. Shahbazi, M. Nateghpour, H. Mirhendi, M. Asmar, M. Ranjbar, L. Faraji, F. Kamali (Tehran, Tabriz, IR)

Introduction: The world wide distribution of *P. vivax* has expanded significantly and the number of cases reported has been on the rise. Approximately 88% of malaria cases in Iran are caused by *Plasmodium vivax*, and in order to management of the disease, understanding the population genetic structure of the parasite is necessary for designing and applying drugs and vaccines. Among many potential candidates, merozoite surface protein-3α gene (PvMSP-3α) is promising target to develop an effective vaccine.
Objectives: This study was designed and carried out to determine the variation of this gene, as a genetic marker, in *Plasmodium vivax* isolates in malarious areas of Iran.
Method: Diversity in PvMSP-3α gene was assessed in 85 *Plasmodium vivax* isolated from four southern and east-southern provinces of the country by PCR/RFLP method. Amplification was performed with two primer pair sets in a nested PCR format and the products were digested by the Enzyme HhaI in RFLP method.

Results: Based on the size of the PCR products, we observed 3 biotypes A (about 1900bp), B (about 1400bp) and C (about 1100bp) of PvMSP-3α gene. Biotype A was predominant. According to RFLP patterns, 10 allelic groups of the gene were observed, that, 7, 2 and 1 groups correspond to the biotype A, B and C, respectively. Mixed genotype and multiple infections were not seen.
Conclusion: We found that RFLP method with HhaI enzyme is a useful method for determining the polymorphism of biotype A of PvMSP-3α gene.

P754 Risk factors and epidemiology of malaria in endemic zones of Venezuela

H. Rodulfo, M. De Donato, B. González, C. Gómez, M. Herrera, L. González, J. Moreno, C. Contreras, L. Villegas (Cumana, Carúpano, Tumeremo, Caracas, VE)

Malaria is the infectious disease with the highest prevalence in the world. In Venezuela, malaria is produced by *Plasmodium falciparum*, *P. vivax* and rarely *P. malariae*. Here, we carry out a metanalysis with all the available data from six different studies from our research group in different areas of Venezuela, as well as all the available information from published and unpublished sources, in order to characterise the risk factors and the epidemiological trends of the malaria disease. The diagnosis of malaria is commonly performed by the microscopic examination through a network of diagnostic centres. OptiMAL, Parasight and ICT have also been used in the field and for comparison reasons with sensibility and specificity values above 85 and 95%, respectively. PCR has also been used for population based and comparison studies, showing a great diagnostic power. In the endemic areas, all these techniques have detected asymptomatic infections caused mainly by *P. vivax*, and PCR have detected a higher proportion of mixed infection, which are most likely playing an important role in the permanence of disease. Malaria incidence in Sucre state was very high between the years 2000–2002, but after 2003 has declined progressively to be close to eradication in most areas. The main transmission factor here is the geographic condition with large swamp areas and the poverty of the communities. In Bolivar, the incidence have always been high, but since 2004, it has become an epidemic grown out of proportions, producing over 90% of the cases for Venezuela, and irradiating to other states. Here, as well as in Amazonas, the main transmission factor is the large selvatic area, the poorly developed health infrastructure and the migration pattern shown by the natives and illegal miners. The vector commonly reported here is A. darlingi, but recently, new species have been pointed out as vectors. Even though Venezuela has been an endemic area for a long time, our results have shown that a large proportion of people do not know how to prevent the disease. The analyses of age group, sex, occupation and cultural habits as risk factors have shown different patterns depending on the studied areas. The use of impregnated mosquito nets, shown to be a very successful prevention measure in many countries, is not widely used in the endemic areas. The official control measures are usually limited to insecticide spaying and early diagnosis.

P755 Malaria in Tunisia: epidemiology, clinical aspects and management

B. Kilani, L. Ammari, H. Tiouiri Benaïssa, R. Abdelmalek, A. Goubontini, F. Kanoun, E. Chaker, T. Ben Chaabane (Tunis, TN)

Objectives: To study the epidemiological, clinical, laboratory features and management of malaria in Tunisia where the disease has been eradicated since 1980. All the cases were imported, mainly from African countries.
Methods: Medical records were reviewed for patients with microscopically confirmed malaria diagnosed at our department during a twenty years period (from august 1986 to december 2006).
Results: 110 patients were included in the study. 90.9% of them were male, and median age was 30 years (range, 14–57). 52.7% of patients were caucasian.34.5% of them had history of malaria and were from Central Africa. Only 26% of cases had taken chemoprophylaxis with poor compliance, mainly in tunisian travellers. Of a total of 110 cases, 87 were caused by *P. falciparum*, 14 by *P. vivax*, 3 by *P. ovale*, 2 by *P. malariae*, 2 patients had dual infection and in 2 cases plasmodia were unspecified. 97% of cases were acquired in subsaharian Africa. All immigrants living in Tunisia have acquired infection in their countries of origin and develop symptoms after a journey. Tunisian people were infected outside the country while travelling for many reasons. 94% of patients gave history of fever; 29% however were afebrile at the time of their presentation. Other commonly but unspecific symptoms were headache, chills, myalgia and gastro-intestinal troubles. 38% of cases had jaundice.
Thrombocytopenia (<150,000/mm3) was the most prominent laboratory feature occurring in 41% of cases. Hemoglobin levels below 12 g/dl were observed in 22%. Leucopenia (<4000/mm3) was noted in 22%. Leukocytosis in 7%. ALT (>22U/l) was elevated in 40% of cases.
Diagnosis of malaria was made in asymptomatic African students in 7 cases. 2 patients (Tunisian) had severe falciparum malaria requiring treatment at the ICU.
For *P. falciparum* cases, mefloquine was the drug of choice, whereas chloroquine associated to primaquine was used for other species. All the patients recoverd well.
Conclusion: Malaria remains a major public health problem in many subsaharian countries. Due to the increased number of international travellers for many reasons, we should be altert to the reintroduction of the prevent disease in our country.

P756 Malaria: between two ports

I. Neves, R. Correia Abreu, M. Guimarães, E. Gonzalez (Matosinhos, PT)

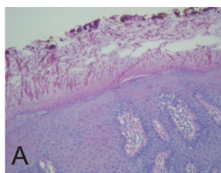
Introduction: For our hospital geographic localisation, between port of sea and airport, ill travelling people are referring to us.
Objectives: To evaluate clinical epidemiology aspects and evolution of the malaria cases.
Methods: Retrospective revision of the interned malaria cases in the last 6 years (January 2001 to April 2007).
Results: In this period 18 malaria cases had been interned (15 men: 3 women), 6 had occurred in 2006; average ages 43±14 (16–62) years. All with recent stay in Africa (Angola, Mozambique, Cameroon, Coast Ivory and Libyan), without previous prophylaxis; 10 live there, 4 had travelled and 4 were sailors embarked that had arrived in port there. In 72% the responsible parasite was *P. falciparum*, 11% *P. vivax* and in 17% was not possible identification. The most common manifestations had been gastrointestinal symptoms, fever and chills. They had presented thrombocytopenia (100%) and anaemia (78%). The complications had been acute renal insufficiency, cerebral malaria and ARDS. That had occurred in no resident endemic area people, with high parasitaemia (10, 20 and 35%) and in a pregnant woman. Patients with complications had necessity of intensive care. They had been treated with quinine and doxycycline, plus primaquine in the others species. The bed average was 8±5 (4–29) days. Mortality was 5.5% (1 case), with favourable evolution in the others.
Conclusions: In Portugal, malaria is an imported disease, most origin in Africans countries of Portuguese official language, and in our case 22% in embarked sailors. As related in literature, the severe cases had happened in not residents, high parasitaemia and predispose conditions. Prophylaxis measures must be taken, especially in travellers and sailors who arrived to endemics areas.

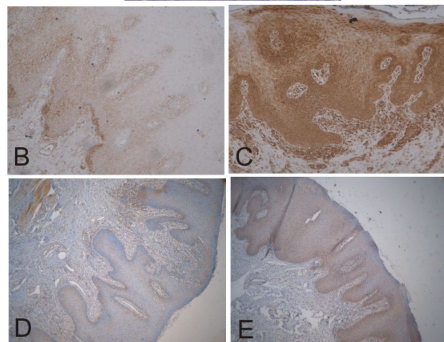
Immunology, host defences and immunotherapy

P757 Differential expression of Toll-like receptors in chronic hyperplastic candidosis

A. Ali, S. Natah, Y. Konttinen (Vantaa, FI; Alberta, CA; Helsinki, FI)

Introduction: The first step in the host defence against oral candidosis is recognising *Candida albicans* through a set of germ-encoded pathogen recognition receptors e.g. Toll-like receptors (TLRs). In man, ten types of such receptors have been identified so far out of which only TLR2, TLR4 and TLR6 have been linked to mediating Candidal ligands e.g. zymosan and mannan.
Materials and Methods: Biopsies from patients with chronic hyperplastic candidosis (n = 5), leukoplakia (n = 5) and healthy mucosa (n = 5) were immunohistochemically stained with the full panel of TLRs (TLR1–9) antibodies to visualize and compare the staining pattern of the epithelial layer in the three categories of tissues.
Results: On analysis, the epithelium of all tissues was divided into three layers: basal, middle and su-perficial. Two of the five chronic hyperplastic candidosis sections showed high numbers of hyphae compared to yeasts, which paralleled a decrease in the expression of TLR2 and an increase in the stai-ning intensity of TLR4. Leukoplakia and healthy tissue sections demonstrated stronger immunostaining of TLRs except TLR9 for the first and the basal layers for the latter.





Discussion: This study supports the concept of negative regulation of TLRs which, for long time, are either ligand-bound (e.g. in chronic hyperplastic candidosis), or not stimulated (in healthy tissue). It also augments the opinion which says that *Candida albicans*, through its hyphae rather than conidia, may exploit TLRs i.e. TLR2, to evade the immune system of the host. Leukoplakia seems to be more alert to lessen the chances of worsening the already-diseased tissue.

P758 Polymorphisms in the mannose-binding lectin and in the MBL-associated serine protease genes in intensive care unit patients with systemic inflammatory response syndrome

A. Smithson, R. Perello, G. Garcia-Segarra, G. Espinosa, D. Tassies, C. Freire, P. Castro, B. Suarez, F. Lozano, J. Nicolas (Barcelona, ES)

Background: Polymorphisms in the mannose-binding lectin (MBL2) and in the MBL-associated serine protease (MASP2) genes have been associated with an increased risk of infections. The aim of the study is to asses the possible association between polymorphisms in these genes and the frequency of infections and death among intensive care unit (ICU) patients with systemic inflammatory response syndrome (SIRS).
Methods: Blood samples from 243 consecutive UCI patients with SIRS (mean age 62.75±15.69 years; 63% men) admitted in our hospital from January 2003 to January 2004 were prospectively collected. For further comparison samples from 104 blood donors were also included in the study. At entry, 94 patients exhibited septic shock, 29 severe sepsis, 49 had sepsis and 71 had a noninfectious SIRS. Mean APACHE II, SAPS II and SOFA score at ICU entry were 17.4 + 6.3, 36.5 + 11.8, 8.7 + 3.1, respectively. In-hospital rate mortality was 30%. Six single nucleotide polymorphism's (–550 G/C, –221 C/G, +4 C/T, codon 52 CGT/TGT, codon 54 GGC/GAC and codon 57 GGA/GAA) in the promoter and the exon 1 of the MBL2 gene and the Asp 105 Gly single nucleotide polymorphism's in the MASP2 gene were genotyped using a sequence-based typing technique.
Results: No significant differences were observed in the frequencies for low expression MBL2 genotypes and for the wild type MASP2 genotype between patients with SIRS (13.02% and 94.4%, respectively) and the healthy controls (15.3% and 97.1%, respectively) (P= 0.86 and P= 0.6, respectively; Chi square test). Although patients with an infectious cause of SIRS had a higher incidence for low expression MBL2 genotypes (15.7%) compared to those with a non infectious SIRS (6.5%), these differences were not statistically significant (P= 0.064; Chi^2 test). No differences were found regarding the frequency for low MBL2 among patients with septic shock or with severe sepsis or among non-survivor ICU patients. The presence of polymorphism's in the MASP2 gene was not associated with a higher rate of infections or mortality.
Conclusions: Although patients with MBL2 genetic polymorphisms causing low MBL2 levels have a tendency to present a higher incidence of an infectious cause of SIRS, the presence of MBL2 or MASP2 genetic polymorphism's do not seem to have a significant impact neither in mortality nor in the severity of infections in ICU patients with SIRS.

P759 Toxin production by meticillin-resistant *Staphylococcus aureus* strains is related to differences in cytokine levels by peripheral blood mononuclear cells

F. Kolonitsiou, A. Spiliopoulou, V. Chini, M. Krevata, E.D. Anastassiou, I. Spiliopoulou (Patras, GR)

Objectives: To investigate the immune system response in terms of secreted cytokines, to the existence of staphylococcal virulence factors among meticillin-resistant *Staphylococcus aureus* (MRSA) isolates.
Methods: Twenty-two, 18 clinical and four reference MRSA strains were characterised on the basis of toxin gene profile by PCRs (PVL, tst, enterotoxins of the egc operon, eta, etb). Clones were defined by agr typing and MLST, while tst expression was calculated by quantitative reverse-transcription PCR (RT-PCR). Peripheral blood mononuclear cells from healthy donors were isolated by standard procedures and were co-cultured in 24-well flat bottom tissue culture plates with live MRSA cells at a ratio of 25:1. Cytokine measurements, using the Luminex® xMAP™ technology, were performed in cell-free supernatants collected at 6 and 12 hours. The 8-plex assay kit was used for simultaneous quantitative determination of the following cytokines: TNFa, IL-1b, IL-6, IL-8, IL-10, IL-12p40, IL-13 and GM-CSF.
Results: MRSA elicited production of detectable amounts of all eight cytokines. A negative correlation was detected between PVL genes carriage and production of GM-CSF at six hours, and TNFa, IL-6, IL-10, IL-13 and GM-CSF at 12h. The presence of tst gene was correlated with release of greater amounts of TNFa, IL-6, IL-8, IL-10, IL-13 and GM-CSF at 6 and 12h. The presence of tst gene correlated with lower levels of IL-12p40 at 12h. Expression level of tst and presence of the remaining superantigens were not related to cytokines' levels. Analysis of agr types and cytokine profile showed that MRSA of agr1 (including tst-positives) induced production of greater amounts of TNFa, IL-6, IL-8, IL-10, IL-13, GM-CSF and IL-12p40 at 12h than agr2 (including egc-positives) and agr3 (including PVL and egc-positives) MRSA. All differences were statistically significant ($p < 0.05$).
Conclusions: Our data reinforce the knowledge that toxic shock syndrome toxin-1 has strong proinflammatory and immunoregulatory properties, perhaps in association with other factors, as it directs immune

system to TH2 response by promoting the release of IL-10 and IL-13 and down-regulating the production of IL-12p40. PVL has a diminished potential towards triggering immune responses, as strains possessing PVL genes elicited production of lower amounts of pro-inflammatory cytokines and cytokines of adaptive immune response.

P760 Influence of combined contraceptive vaginal ring on vaginal microflora and immunity

V. Orlova, Y. Naberezhnev, O. Lebedeva (Belgorod, RU)

Objectives: to establish influence of vaginal ring on microbiocenosis of low female reproductive tract.
Methods: 31 female women age of 20–25 years old were examined before and after 3-month usage of contraceptive vaginal ring (NuvaRing). Vaginal ring is combined low-dosed hormonal contraceptive which releases 120 μg of etonogestrel and 20 μg of ethinyloestradiol daily. The samples of vaginal discharge were inoculated into a culture medium (Columbia base agar, blood agar, Man Rogosa Sharpe medium, semisynthetic growth medium, McConkey agar, *Gardnerella vaginalis* agar and Sabouraud agar) and cultured for anaerobic and aerobic bacteria. Secretory immunoglobulin, IFN-gamma, IL-4, lysozyme in cervico-vaginal mucus were detected by ELISA. Data were analysed using Statistica 6.0 (StatSoft, USA).
Results: After vaginal ring usage considerable changes of vaginal microbiocenosis structure were observed. Amount of *Lactobacillus* increased from 10^4 to 10^6 colony forming units (CFU) and *Bifidobacterium* from 18.2±1.2 to 44.4±6.1 CFU ($p \leqslant 0.05$). Percentage of women, having three-component microbial association (*Peptostreptococcus*, *Staphylococcus* and *Streptococcus*) decreased from 66.7±8.8% to 46.7±9.1%. Nevertheless, number of *Candida albicans* increased from 10^2 to 10^4 which gave rise to symptomatic yeast infection.
Elimination of cocci during NuvaRing usage could be consequence of elevation of secretory immunoglobulin (from 47±12.5ng/ml to 94.5±22.1 ng/ml) and IL-beta (from 95.7±29.1 pg/ml to 130.2±29.1pg/ml) ($p \leqslant 0.05$). High rate of *Candida* detection, apparently, could be result of high local level of estrogen among women using contraceptive vaginal ring.
Conclusion: Thus, our studies showed increasing concentration of lactobacilli and bifidobacterii, and cocci elimination, wich is favourable for antiinfectious resistance of female reproductive tract. Meanwhile, high risk of yeast infection appearance doesn't make possible to recommend this type of contraception for women with recurrent candidiasis, diabetus mellitus, AIDS and etc.

P761 Immunmodulatory potencies of linezolid in a LPS model of human whole blood

C. Lambers, M. Will, C. Wagner, M. Zeitlinger (Vienna, AT)

Objectives: Gram-negative sepsis resulting in septic shock is one of leading causes of death in critically ill patients. One important determinant of mortality is the release of endotoxin, which is a structural component of LPS. It is generally accepted, that the first mediators in the cascade of LPS-induced events are cytokines, like TNF-alpha and IL-1beta. Because treatment options are limited, a wide range of therapeutic strategies are still under investigation, but convincing reduction of mortality is still lacking. New approaches are focused on immunmodulatory effects of antimicrobials. Several studies investigating Linezolid in different models of Gram-negative sepsis showed significant reduction of pro-inflammatory cytokines but used un-physiologically high doses of LPS. The aim of our study was to characterise the immunmodulatory effects in a model of human whole blood with concentrations of LPS and Linezolid reflecting physiological conditions.
Methods: Whole blood from 10 healthy volunteers was incubated with 50 pg/mL LPS W/o 13 μg/mL Linezolid for 2 and 4 h. RT-PCR was performed from messengerRNA (mRNA) of IL-1β, IL-6 or TNFα, 18sRNA was used as control. Protein levels of the supernatant were measured using ELISA for IL-6 and TNFα.
Results: Incubation of human whole blood with LPS significantly increased mRNA levels of cytokines compared with baseline. The addition of Linezolid significantly reduced mRNA levels of IL-1β (−49%; $p < 0.01$), IL-6 (−49%; $p < 0.01$) and TNF-α (−61%; $p < 0.02$) after 2 hours. In addition, after 4 hours reduction on mRNA levels of IL-1β (−49%; $p < 0.01$), IL-6 (−25%; $p < 0.03$) and TNF-α (−32%; $p < 0.04$) were observed. Although LPS stimulation increased levels of IL-6 and TNFα between 100 and 1000-fold, in contrast to mRNA no reduction by addition of Linezolid was observed on protein level.
Conclusion: The previously assumed immunmodulatory effects of Linezolid were confirmed in our in vitro sepsis model on gene expression level. However, differences to previous findings which have shown significant reduction on protein levels were observed. This discrepancy might be mainly ascribed to methodological differences, since compared to previous work more physiologic conditions were employed in the present setting.

P762 Influence of linezolid on phagocytosis and killing of Gram-negative bacteria by polymorphonuclear neutrophils

T. Grüger, N. Schnitzler, S. Nidermajer, K. Brandenburg, J. Zündorf (Bonn, DE)

Objectives: In a recent phase III clinical trial on linezolid it became obvious that in the linezolid treatment arm more patients acquired Gram-negative catheter related blood stream infections. It was postulated, that linezolid may trigger the acquisition of Gram-negative infections associated with higher mortality rates despite adequate anti-Gram-negative therapy. Therefore, we analysed the impact of linezolid on phagocytosis and killing of Gram-negative bacteria by polymorphonuclear neutrophils (PMN). Phagocytosis and killing of pathogenic microorganisms by PMN are of high relevance for the prognosis of patients suffering from bacterial infections.
Methods: Whole-blood samples were taken from healthy volunteers and incubated with linezolid in clinical relevant concentrations (5, 20 and 50 mg/L) and compared to a drug-free control. CD11b-expression of PMN was evaluated using fluorescence-labelled mAB. To measure phagocytosis, fluorescence-labelled Gram-negative bacteria (*Escherichia coli*, *Burkholderia cepacia*, *Pseudomonas aeruginosa*) and Gram-positive control (*Staphylococcus aureus*) were added to the blood. Bacteria : PMN ratio was adjusted to 5:1. Phagocytosis was stopped after 5, 15, 30, and 60 min, respectively. Samples were subsequently analysed by flow-cytometry.
To evaluate the influence of linezolid on killing of bacteria whole blood was incubated with 0 (control), 5, 20 and 50 mg/L linezolid, respectively. Killing of bacteria in whole blood was determined after three hours of incubation by plate counting.
Results: Linezolid impaired CD11b-expression of PMN in a concentration-dependent manner up to about 15 percent. Additionally, linezolid also impaired phagocytosis of *E. coli* (5 to 29%) and to a lower extend of *B. cepacia* (⩽ 15%) and *P. aeruginosa* (⩽ 10%) in a concentration-dependent manner. In contrast killing of tested Gram-negative and Gram-positive bacteria were not affected by linezolid compared to the control.
Conclusion: Our data reveal a negative, concentration-depended influence of linezolid on the CD11b-expression of PMN and on phagocytosis of *E. coli* and to a lower extent of *B. cepacia* and *P. aeruginosa* but not of *S. aureus*. Despite no observable influence of linezolid on the killing of *S. aureus*, *E. coli*, *B. cepacia*, and *P. aeruginosa* an impaired phagocytosis of Gram-negative bacteria might be critical, especially, in patients with otherwise impaired immune system even if patients receive additional adequate anti-Gram-negative therapy.

P763 Granzyme K levels and NK cell lytic activity in experimental mice challenged with LPS and/or IL-2+IL-12

M. Rucevic, L.D. Fast (Zagreb, HR; Providence, US)

Objectives: Widespread activation of the innate immune system by infecting pathogens results in uncontrolled systemic release of an array

of inflammatory mediators that generate clinical sepsis. Recently, we found that the levels of Granzyme K (GrK), a potent lymphocyte serine protease, correlate with the stage of sepsis but, the reason for increased GrK levels during inflammatory responses/sepsis is unclear. Since natural killer (NK) cells, which are know to be critically involved in the course of sepsis may also be responsible for the production of increased GrK levels, the aim of the present study was to investigate the changes in GrK levels along with the NK cells lytic activity in experimental animal models.

Methods: Recipients C57BL/6 mice were injected with bacterial lipopolysaccharide (LPS, 25 μg) in the first experimental model. In the second model, inflammatory response was induced in recipients by combined injection of cytokines, interleukin (IL)-2 and IL-12 (3×10^5 U rhuIL-2 + 1 μg rmuIL-12) which were also shown to be synergistic inducers of granzymes message. Our previously developed GrK-ELISA system was used to measure the plasma levels of GrK in LPS and/or IL-2+IL-12 injected recipients. Subsequently, the NK cells lytic activity was examined by testing the ability of single cell suspension prepared from recipient spleen cells to lyse the NK sensitive target, 51Cr-labeled YAC cells.

Results: Increase in GrK levels in mice plasma follow the increase in NK cell lytic activity in LPS challenged mice while in IL-2+IL-12 challenged mice no significant increase in NK cell lytic activity was observed. Furthermore, the changes in GrK levels in mice plasma of both experimental models were found to correlate with the changes in GrK levels of septic patients.

Conclusions: GrK could constitute at least one of the mechanisms by which NK cells contribute to systemic inflammation/sepsis. In addition, the results confirmed the role of GrK in sepsis pathology and further indicate that it may be a potential diagnostic marker and/or novel therapeutic target for further treatments of this life-threatening disease.

P764 Chronic infection with hepatitis B virus is not associated with early senescence of CD8+ T lymphocytes

P. Carotenuto, A. Artsen, A.D. Osterhaus, O. Pontesilli (Rotterdam, NL)

Objective: To assess whether CD8+ T lymphocyte phenotype in patients with chronic hepatitis B virus (HBV) infection is compatible with accelerated senescence, as observed in infection with other persistent viruses, namely cytomegalovirus (CMV).

Methods: T lymphocyte subpopulations have been quantified in separated peripheral blood mononuclear cells from 24 chronic hepatitis B (CHB) patients (age 18–56 years), 28 healthy age-matched blood donors and 16 convalescent patients with acute hepatitis B (AHB). Expression of CD45RA and co-stimulatory molecules CD27 and CD28, determined by 4-colour direct immunofluorescence and flow cytometry, was used to establish the maturation phases of CD8+ T lymphocytes according to the sequential loss of CD45RA, CD28 and CD27 (combined with re-expression of CD45RA during quiescence) according to the model proposed by Appay and Rowland-Jones (Semin. Immunol.2004;16:205–212). Percentages of lymphocytes in each subset were compared by Student's t test and the differences scored as significant by $p < 0.01$.

Results: Comparable percentages of CD45RA+ CD8+ T lymphocytes were found in healthy controls (60±15% of CD8+ T cells) and CHB patients (65±14%), but AHB patients showed significantly lower percentages (46±19%). Truly naive (CD45RA+ CD27+ CD28+) CD8+ T lymphocytes were significantly more represented in CHB patients (23±16%) than in both healthy controls (11±11%) and AHB patients (11±7%). The AHB patients showed a relative expansion of the recently activated antigen-experienced (CD45RA- CD28- CD27+, intermediate phenotype) CD8+ T cells whereas the supposedly quiescent analogous subset (CD45RA+ CD28- CD27+) was significantly smaller in the CHB patients (20±12%) compared with healthy controls (36±21%). No significant difference was found in the late (CD28− CD27−) antigen experienced subsets.

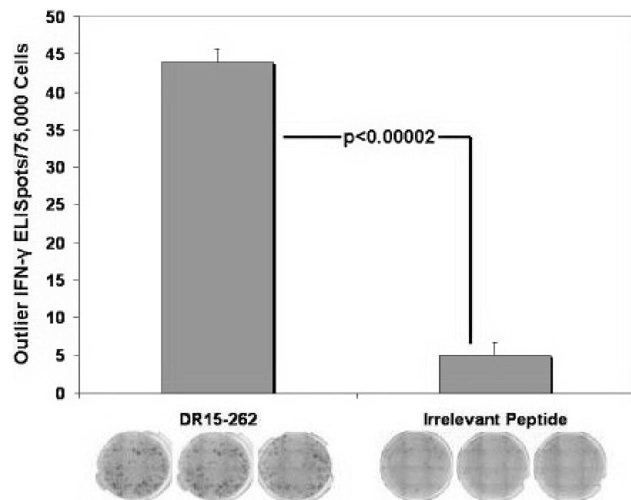
Conclusion: The data suggest that chronic infection with HBV is not associated with accumulation of terminally differentiated CD8+ T lymphocytes and a corresponding early senescent phenotype, but otherwise by a larger input or accumulation of naive lymphocytes in peripheral blood.

P765 Generation of influenza recombinant haemagglutinin-specific lymphocytes from cordblood-derived dendritic cells: immunotherapy model from an unprimed source

A. Safdar, W. Decker, E. Shpall (Houston, US)

Background: Cordblood-derived (CB) is an important source of mostly unprimed stem cells. We sought to generate CB-derived dendritic cells (DC) immunotherapy against influenzavirus.

Methods: Recombinant hemagglutinin (rHA) was expressed in insect (SF9) cells by recombinant baculovirus. The HA gene of influenza A New Caledonia/20/99 (H1N1) influenza virus was independently cloned into the plasmid baculovirus expression vector pPSC12. Generation of Immature DCs. Umbilical cord blood units discarded from the MDACC CB bank were used after IRB approval. DC Loading and Maturation. After six days of culture in GM-CSF and IL-4, immature dendritic cells were loaded with rHA protein. Immature dendritic cells were suspended at a concentration of 4×10^7 cells/ml, mixed with rHA and incubated for 10 minutes on ice in an electroporation cuvette. T-cell Priming and Re-Stimulation. Upon maturation of loaded DCs, they were incubated at a ratio of 1:10 with autologous non-adherent PBMCs (typically 50% CD3+), plus IL-12. ELISpot Assay. Typically, 10^4 to 10^5 lymphocytes from each culture were mixed at a ratio of 10:1 with thawed dendritic cells, plated in triplicate on anti-IFN-gamma coated ELISpot plates (BD Biosciences) and cultured overnight (12–18 hours). ELISpots for with putative HA peptide epitopes were performed similarly using 1×10^5–2×10^5 lymphocytes incubated overnight in 3.75 μg/ml peptide.



Results: rHA-specific lymphocytes demonstrate identifiable HLA-restriction. As demonstrated by Figure, HA-primed lymphocytes (HLA DRbeta1*1503) from a different CB demonstrated a nine-fold increase in statistically large spots when restimulated with the DR15–262 epitope ($p < 0.00002$). These data suggest that 1 in 1,900 of the HA-specific T-cells were DR15–262 restricted in a highly-specific fashion. Total ELISpot numbers ($p < 0.0002$) and total IFN-gamma release ($p < 0.00004$) between lymphocytes restimulated with DR15–262 and the control peptide were statistically distinct as well. Incubation of peptide DR15–262 in conjunction with HA-primed/DR15- lymphocytes or in conjunction with adenoviral hexon-primed (irrelevant) lymphocytes did not demonstrate significant numbers of IFN-γ spots.

Conclusions: The results demonstrate that, despite the generally naive of CB lymphocytes, influenza HA-specific responses can be generated ex vivo and could be potentially be used to enhance immune reconstitution following allogeneic stem cell transplantation.

P766 **Staphylococcal activation of plasmacytoid dendritic cells requires preformed IgG**

M. Parcina, C. Wendt, K. Heeg, I. Bekeredjian-Ding (Heidelberg, DE)

Objectives: Induction of type I interferon (IFN-I) production has previously been detected in response to infection with intracellular bacteria and upon stimulation of human PBMC with extracellularly located *Staphylococcus aureus* or *Escherichia coli*. In spite of these observations the molecular mechanism triggering IFN-I by extracellular bacteria has so far not been elucidated. The aim of the study was to provide information on the mechanism involved in IFN-I induction by staphylococci.
Methods: Human plasmacytoid dendritic cells (PDC) were enriched from PBMC with BDCA4 microbeads. PDC were resuspended in culture medium w/o human serum and stimulated with staphylococci. IFNa secretion was quantified by ELISA. Anti-staphylococcal immunoglobulin was detected by Western Blot.
Results: Here we demonstrate that staphylococcal activation of human plasmacytoid dendritic cells occurs in a species-specific manner. Interestingly, all donors tested responded to *S. aureus* while only few donors responded to *S. epidermidis* and other coagulase-negative staphylococci. PDC activation was subsequently found to depend on the donor serum. We further show that IFNa levels depend on the concentration of preformed antigen-specific IgG. Moreover, *S. epidermidis*-responsive and non-responsive donors can be distinguished by the presence or absence of anti-*S. epidermidis* Ig.
Conclusion: PDC recognition of extracellular bacteria requires a prior humoral immune response with antigen-specific IgG formation. Since IFN-I primes immune cells for a more efficient response to pathogens our data suggest that the human immune response to *S. aureus* is more efficiently unleashed than that to other staphylococci. Furthermore, patients at risk for developing sepsis may benefit from vaccination against common bacterial pathogens.

Pathogenesis and diagnosis of viral infections

P767 **Mapping of the binding domains of the Newcastle disease virus phosphoprotein in P–L and P–(NP-RNA) complexes**

F. Jahanshiri, K. Yusoff, J. Abdulah, R. Abdul rahim (Kuala Lumpur, MY)

Newcastle disease virus (NDV) is an avian pathogen which affects the poultry industry worldwide. Outbreaks of the disease known as Newcastle disease (ND) often result in mass culling of the infected chickens. NDV has also oncolytic activities against human malignancies which lead to tumour apoptosis and cell death. Besides that NDV can serve as a viral vector to express and deliver foreign genes which is useful in vaccination and gene therapy. To identify the mechanisms involved in NDV pathogenesis as well as its anti cancer properties, the understanding of the mechanisms involved in the transcription and replication of the virus is of fundamental importance. One way to characterise such mechanisms is to identify the involvement of the viral proteins and their interacting partners. It has been shown in other paramyxovirues that the phosphoprotein (P) plays a central role in the transcription and the replication of the viral genome. Together with the large (L) protein, it forms and stabilizes the active RNA-dependent RNA polymerase complex. It also mediates the interaction between the L protein subunit of this complex with the viral nucelocapsid (NP-RNA) template comprising a nucleocapsid tightly bound RNA genome. Employing a yeast-two hybrid system the presence of P-L interaction in NDV was investigated. However, due to the low expression level of L protein yeast, no interaction was observed. Therefore, an in vitro co-translation approach was carried out to identify P-L interaction. The result showed that NDV P protein is also involved in the stabilisation of L protein. To identify the presence of NDV P–(NP-RNA) interaction and the involved domain(s), co-immunoprecipitation was performed. Purified NP:-RNA template along with in vitro translated P or its derivatives were separately co-immunoprecipitated using anti-His antibody. The results revealed that the immediate N-terminal of P protein is involved in its interaction with NP-RNA template.
In conclusion, the current study has delineated the key interacting partners of NDV P. This knowledge will be useful for structural and functional exploration of this protein.

P768 **Host cellular responses in Nipah virus infection**

L.Y. Chang, S.S. Hassan, S. AbuBakar (Selangor, Ipoh, Kuala Lumpur, MY)

Objectives: Nipah virus (NiV) is a zoonotic infectious virus that causes severe to fatal central nervous system infection in human during an outbreak in Malaysia in 1998. During the outbreak, NiV also causes disease in pigs. Unlike the infection in human, infected pigs normally present with respiratory distress syndrome and the disease is less severe in comparison to human infection. The present study was undertaken to investigate and understand the possible molecular mechanisms that may contribute to the difference in pathogenicity of NiV infection in the two hosts, human and pigs.
Methods: We examined NiV infection and replication in selected cell culture systems representing the two hosts, human and pigs. The state of dysfunction of the NiV-infected cells was then examined using proteomic approaches.
Results: Infection of four different cell types representing the two host organisms using NiV shows that the virus establishes productive infection in all the cell types examined. There are no differences in the capacity to support NiV replication between fully susceptible porcine stable kidney cells (PS) and human lung fibroblasts cells (MRC-5), respectively. However, there are differences between these cells, and human neuronal cells (SK-N-MC) and monocytes (THP-1), in the ability to support NiV replication and virus release. The SK-N-MC cells are less able to support NiV infection when compared to the PS cells. Subsequent examination of the changes in cellular host response as a result of NiV infection in both human and pig cells identified a total of 15 differentially expressed proteins. Most of these proteins are involved in virus replication or RNA synthesis, and proteins associated with the cellular functions of the mitochondria or the induction of apoptosis. The potential importance of these differentially expressed proteins includes the regulation of NiV replication in the two hosts as well as the manifestation of cellular cytopathic responses to the infection.
Conclusion: The proteomic analysis of NiV-infected cells of human and pigs identified differences in the key cellular pathways and events occurring during NiV infection in the two hosts, respectively, that could contribute to the differences in manifestation and severity of NiV infection.

P769 **Crimean-Congo haemorrhagic fever virus infects peripheral blood mononuclear cells and does not disrupt tight junctions in MDCK-1 cells**

A-M. Connolly-Andersen, K-E. Magnusson, A. Mirazimi (Solna, Linköping, SE)

Objectives: Crimean Congo Haemorrhagic Fever is characterised by severe bleeding with mortality rates averaging 30%. There is no verified treatment or prophylaxis making this a grave disease to contract. The molecular mechanisms underlying pathogenesis are completely unknown, however a few theories have been postulated for other viral haemorrhagic fevers. It could be a direct effect of viral infection on cells that can cause haemorrhage (through disturbing tight junctions) or it could be a host mediated effect. If infection disrupts tight junctions, that could be the cause of blood vessel leakage explaining the observed haemorrhages.
In this study we have analysed the effect of viral infection on tight junctions in different model cell lines. We have also studied the ability of Crimean Congo Haemorrhagic Fever Virus (CCHFV) to infect different human cells.
Methods: In order to study viral effect on tight junctions, different polarised cells were grown on Transwell semi-permeable filters and

transepithelial electrical resistance measured. Visualisation of the tight junction proteins occludin and ZO-1 was performed by indirect immunofluorescence microscopy, to study localisation of these proteins upon infection.
Infectivity of cells was verified by western blotting, PCR and indirect immunofluorescence.
Results: Tight junction integrity was analysed by both TER and IF, and there was no measurable disruption indicating viral infection does not disturb tight junction integrity.
Viral protein and RNA could be found in different cells.
Conclusion: There was no measurable effect on tight junction integrity in highly polarised cells.

P770 Replication of Vaccinia virus on PBMC is restricted by mediators of innate immunity

C. Castilletti, L. Bordi, C. Agrati, E. Lalle, F. Carletti, E. Cimini, M.R. Capobianchi (Rome, IT)

Objectives: No detailed studies have been conducted on interactions of poxviruses with the immune system, relevant to clarify pathogenic mechanisms of poxviruses infection, and to improve poxvirus vaccine vectors and immunomodulatory strategies. The aim of our study was to better understand the cellular targets of Vaccinia Virus (VV) infection and their consequences of infection for cells involved in the generation of antiviral immune responses.
Methods: The ability of VV to productively infect normal PBMC and different cell subpopulations (CD14+, CD4+/CD8+ and CD4−/CD8−) was determined by back titration of infectivity and quantitative detection of viral genome in kinetic studies. In the same experiments the extent of induction of IFN alpha and/or gamma, was measured at both mRNA and protein level.
Neutralising antisera against IFN alpha and gamma were used to establish if the low replication rate of VV in PBMC is due to the activation of the IFN system.
Results: VV replication efficiency in PBMC is generally low, and is restricted to few PBMC subpopulation (namely: CD14+ and CD4−/CD8−), while resting T cells do not support VV replication. Neutralising antibodies to IFN alpha and gamma strongly increase the replication of VV in CD14+ and CD4−/CD8− cells, indicating that these cytokines are induced by VV, and are at least partially responsible for restricted replication in PBCM subpopulations.
Conclusions: Our findings indicate that mediators of innate immunity, such as IFN system, are important factors in the control of orthopoxvirus replication in white blood cells, and may be exploited as therapeutic strategy to counteract severe infections, that can occur as result of zoonotic exposure in humans.

P771 Avian influenza H5N1 virus is able to disregulate interferon response activation in human PBMC

E. Lalle, L. Bordi, R. Chiappini, A. Sacchi, M.R. Capobianchi, C. Castilletti (Rome, IT)

Objectives: The extraordinary spread of highly pathogenic avian influenza A (HPAI) H5N1 viruses has resulted in devastating outbreaks in domestic poultry and sporadic human infections with a high fatality rate. Unlike most other influenza infections, H5N1 infection causes a systemic disease. The underlying mechanisms for this effect are still unclear. Impaired Interferon (IFN) response may be involved in enhanced pathogenicity of HPAI H5N1 infection. We investigate the ability of both H5N1 and H3N2 viruses to trigger the activation of the IFN system in human PBMC in vitro.
Methods: Human, freshly collected, PBMC from healthy donors were exposed to either HPAI H5N1 or H3N2 to assess the extent of induction of IFN alpha and gamma at both mRNA and protein level. Moreover, we used quantitative Real-time RT-PCR to compare the mRNA levels of IFNAR-1 and of downstream cascade of IFN response genes, such as PKR, MxA, OAS.
Results: The HPAI H5N1 virus was more effective than H3N2 in inducing IFN alpha and gamma, at level of both intracellular mRNA and released protein. On the contrary, mRNA for IFN stimulated genes (ISGs) were less effectively induced in PBMC infected with H5N1 virus as compared to H3N2. Moreover, IFNAR-1 mRNA levels were reduced in PBMC exposed to H5N1 as compared to H3N2 and to unstimulated PBMC.
Conclusion: Our data suggest that the H5N1 virus, although being able to induce IFN alpha and gamma to a greater extent than the less pathogenic H3N2 subtype, is able to attenuate the response to IFN alpha by reducing the extent of IFNAR-1 expression, so that the downstream IFN activated cascade is less efficient as compared to H3N2. As IFN system represents one of the first lines of defence against virus infections, the impairment of this critical host innate immune response may contribute to the high virulence of HPAI H5N1 virus in humans.

P772 Comprehensive analysis of genomic sequences of oncogenic viruses in colorectal cancer

V. Militello, L. Barzon, M. Trevisan, C. Militello, G. Palù (Padua, IT)

Objectives: The aim of this study is to investigate whether there is an association between oncogenic viruses and colorectal preneoplastic lesions and carcinomas.
Methods: This study was conducted in tissue samples from 113 patients diagnosed with colorectal polyp or cancer, including 72 archival colorectal cancers and matched adjacent mucosa and biopsies of colorectal cancers, polyps, and adjacent mucosa, which were longitudinally collected from 41 consecutive patients. Biopsies from 10 subjects, who underwent colonoscopy without detection of benign or malignant lesions, were used as controls. The presence of the herpesviruses (EBV, HCMV) and the polyomaviruses (JCV, BKV, SV40) was investigated by quantitative real-time PCR. Detection and typing of HPV was performed by PCR and sequencing.
Results: EBV-DNA was detected in 30% of cancers and polyps (without significant differences between benign and malignant lesions) and in 14% adjacent mucosa (lesion vs adjacent mucosa, $P < 0.05$); HCMV-DNA was detected in 4% of cancers and in 2% of adjacent mucosa (P=NS). In control biopsies, EBV and HCMV DNA was detected in 50% and 10% of cases, respectively. Both EBV and HCMV were detected in tissue samples at very low viral genome equivalents/cell, consistent with lymphocyte/macrophage infiltration. HPV-16 was detected in 4% of cancers (all rectal carcinomas), but not in adjacent mucosa nor in control samples. No polyomavirus DNA was detected in any sample.
Conclusions: This study seems to exclude a role of EBV, HCMV, and polyomaviruses in the pathogenesis of colorectal cancer, whereas high risk HPV-16 could be involved in some cases of rectal carcinoma. These results are at variance with some reports in the literature, which demonstrated a high prevalence of JCV and HCMV sequences in colorectal cancer and suggested these viruses could have a role in tumorigenesis.

P773 Human cytomegalovirus infects adrenocortical cells and stimulates adrenal steroidogenesis

M. Trevisan, G. Masi, U. Matkovic, G. Palù, L. Barzon (Padua, IT)

Objectives: Based on our observation that human cytomegalovirus (HCMV) genome and expression of both early and late genes are frequently detected in functioning adrenocortical tumours, aim of this study was to investigate whether HCMV infects and replicates in adrenocortical cells in vitro and the effects of viral infection on steroidogenesis and adrenocortical cell growth.
Methods: human adrenocortical carcinoma (ACC) cell lines NCI-H295 and SW-13 and primary ACC cell cultures were infected with clinical isolates of HCMV and with the HCMV strain AD169 and analysed by immunofluorescence assay. At different time points, steroid hormones were measured in culture medium, while cells were harvested for RNA extraction and evaluation of gene expression by microarray analysis.

Infected cells were tested with BrdU assay and stained with propidium iodide and annexin-V antibody for the evaluation of apoptosis, cell proliferation, and cell cycle.
Results: all the HCMV strains employed resulted in productive replication in ACC cells, as demonstrated by expression of both early (pp72) and late (pp65) viral antigens. Analysis of the kinetics of viral replication in ACC cells showed efficient production of infectious viral particles. HCMV infection of NCI-H295R cells significantly increased the production of cortisol and 17β-estradiol, an effect which was probably due to viral replication/viral gene expression rather than interaction of virus particles with the host cell, as demonstrated by experiments with UV-inactivated virus. This effect on steroid hormone production was accompanied by a marked induction of the storoidogenic enzymes CYP11B1 and CYP19. Moreover, HCMV infection showed a cytopathic effect on adrenocortical cells outlined by induction of apoptosis, cell vacuolisation, inhibition of cell proliferation, and increase of cellular S phase. Finally, evaluation of global human gene expression profile by microarray analysis showed that HCMV infection induced genes involved in growth control and stress response. Bayesian analysis unveiled two key genes, P2Y11 and P2X4, induced by HCMV infection and involved in adrenal steroidogenesis.
Conclusion: these results demonstrate for the first time that HCMV infects and replicates in human adrenocortical cells. HCMV infection of adrenocortical cells stimulates cortisol and estrogen production and changes cellular gene expression profile toward a condition of stress response.

P774 Evaluation of the AcroMetrix® OptiChallenge Inhibition Panel in different QIAGEN® sample preparation protocols automated on the QIAcube

C. Kupfer, Y. Lee, G. Schulte, M. Sprenger-Haussels (Hilden, DE)

Objectives: The Clinical and Laboratory Standards Institute recommends that all clinical assay performances should be evaluated in the presence of potentially interfering substances to validate assays, to quantify interference effects, and to confirm interference in patient samples (CLSI EP-7-A2). This is particularly important for homebrew assays, where no data is available from the manufacturer on the performance of the assay in the presence of such substances. Clinical laboratories are responsible for verifying in all assays that the levels of interfering substances in their patient population are within an acceptable range.
Methods: The AcroMetrix OptiChallenge Inhibition Panel is a 7-member panel that mimics patient plasma containing potentially interfering substances that frequently occur due to clinical conditions such as hemolysis, icterus, or lipaemia.
We have evaluated the interference effect of the inhibition panel members on the performance of different silica-based sample preparation protocols on the QIAcube and their manual reference methods. Common bloodborne viruses, such as HCV and HBV, and different internal controls were spiked into each panel member in equal quantities.
Results: All tested automated sample-preparation protocols tested performed well and removed a good amount of the interfering substances when specific amounts of each analyte spiked were quantified in the presence of potentially interfering substances and compared with no-interference control. Results of the automated protocols were comparable to the manual reference methods. Different extraction and amplification chemistries show different susceptibilities to single interfering substances.
Conclusion: The automated QIAGEN extraction protocols, tested for isolation of viral RNA and DNA, have been proven to serve as reliable and robust methods. The inhibition panel was only minimally diluted, so the extraction systems were tested at the highest possible level of interference. The tested protocols were able to remove the majority of potentially interfering substances.
The OptiChallenge Inhibition Panel provides an effective tool to monitor the performance of nucleic acid extraction and amplification methods and simplifies the required validation processes by providing plasma samples that mimic interfering patient samples. This panel could be useful in QC release testing of DNA and RNA extraction and amplification systems.

P775 Importance of molecular detection for diagnosis and monitoring mumps-virus infection

E. Royuela, A. Castellanos, M.E. Guisasola, J.C. Sanz, M. Mosquera, C. Sanchez-Herrero, F. De Ory Manchón, J.E. Echevarría for the CIBERESP Investigators Group

Objectives: Mumps-virus (MVs) is a paramyxovirus that causes fever, headache and swelling of the salivary glands. Complications such as meningitis, encephalitis and orchitis are relatively frequent, however permanent sequelae are rare. Routine vaccination included in immunisation schedule has resulted in a dramatic drop in the number of reported mumps cases, although, outbreaks in vaccinated population have recently occurred, including large outbreaks worldwide. World Health Organization (WHO) recommendations for diagnosis of mumps infection includes isolation of MVs from clinical specimens or seroconversion (or significant rise in serum mumps IgG titre) or positive serological test for mumps-specific IgM antibodies. These recommendations do not include molecular detection using RT-PCR. Our goal was to evaluate the importance of RT-PCR detection methods for MVs detection in clinical samples.
Methods: For that reason, we developed an study including serological and RT-PCR detection methods, in which 593 complete cases were analysed (complete cases include serum and saliva and/or urine samples).
Results: From these analysed samples, 296 (49.9%) were positive, being 30.7% IgM and RT-PCR positive, 29.7% IgM positive but RT-PCR negative and a surprising 39.5% IgM negative but RT-PCR positive. This 39.5% positive to RT-PCR showed 97.43% IgG positive, indicating a secondary vaccine failure since reinfection was discarded after analysis of patients vaccination antecedents.
Conclusions: Data presented in this study demonstrate the importance of molecular detection methods for diagnosis of MVs infection and for the evaluation of vaccine failure previously reported, since using only serological methods the MVs infection incidence is understimated.

P776 Serological and molecular diagnosis of measles using oral fluid samples

V. Hutse, K. Van Hecke, R. De Bruyn, O. Samu, T. Lernout, J.J. Muyembe, B. Brochier (Brussels, BE; Kinshasa, CD)

Objectives: Measles Virus (MV) is responsible for a very contagious disease characterised by high fever, coryza, cough, conjunctivitis followed by the appearance of a maculopapular rash. Despite the development of a combined vaccine (Measles-Mumps-Rubella), measles remains a major cause of mortality in developing countries and a cause of continuous outbreaks in more industrialised countries. Currently measles is diagnosed by traditional serological and molecular assays on serum and nasopharyngeal secretions.
The introduction of oral fluid as an alternative medium to serum would open many perspectives. In advantage to venepuncture, the collection of oral fluid is less invasive, less painful, less expensive (i.e. no trained personal required) and safer (prevention of needle stick injuries). Since measles appears mostly in children a non invasive sample collection like oral fluid would be an enormous asset to determine measles RNA and antibodies as quick as possible in case of/or to avoid epidemic measles outbreaks.
Methods: In this study seventy-three measles positive and fifty measles negative tripled samples (serum, oral fluid and nasopharyngeal secretions) were analysed. Samples were collected in the Democratic Republic of Congo (Kinshasa) by the National Measles Laboratory. In addition 22/50 negative samples came from volunteers of the Scientific Institute of Public Health, Belgium (IPH). Oral fluid samples were collected using an Oracol collection device (Malvern Medical Developments) and were controlled for quality and quantity by an IgG quantification assay.

The detection of measles antibodies was performed by commercialised ELISAs. An in-house nested RT-PCR has been developed for the detection of measles RNA.

Results: The anti-measles IgM ELISA (MicroImmune) on oral fluid has been validated against the IgM ELISA (Dade Behring) on serum (=golden standard) and resulted in a sensitivity and specificity of respectively 93.1% and 100%. The validation of a molecular nested RT-PCR on oral fluid was performed against the standard assay on nasopharyngeal secretions and gave a sensitivity and specificity of 100%.

Conclusion: The obtained results confirm that both serological and molecular oral fluid assays are suitable for routine use.

The use of oral fluid samples may also promote the participation rate of patients, GP's and paediatricians in the Belgium measles surveillance system and other epidemiological studies in the framework of WHO elimination programme.

P777 Should PCR replace the indirect fluorescence antigen test for detection of Varicella zoster on skin swabs?

D. Ursi, K. Bergs, H. Goossens, M. Ieven (Edegem, BE)

Background: An indirect fluorescence antigen (IFA) test is classically performed for routine diagnosis of varicella zoster (VZV) infection on skin swabs. In this study the results of the IFA tests were compared to the results of PCR on skin swabs collected between January 2003 and June 2007.

Methods: Skin swabs were collected and immediately transported to the lab in virus transport medium (VTM). DNA extraction was performed on 200 μl VTM with a Qiagen blood kit (Qia). From august 2006 on, DNA extraction was performed with a NucliSens easyMAG extractor (EM) (bioMérieux). Elution volumes were 50 μl for Qia and 55 μl for EM.

PCR was performed according to the assay of Griffais et al. (NAR, 1991). From Sept 2005 on, this assay was replaced by a real-time PCR assay described by Stöcher et al (J.Clin. Virol. 2003).

The IFA test was performed by spotting the swab on a multispot plate. After addition of a MAb against VZV followed by incubation with a FITC labeled conjugate (Argene), the spots were analysed with a fluorescence microscope. The test was interpreted as positive, negative or not interpretable if the number of skin cells in the sample was too low.

Results: Between January 2003 and June 2007 a total of 380 swabs were analysed with IFA. A total of 283 swabs were scored as not interpretable (74.5%). Sixty one swabs were scored as negative (16%) and 36 as positive (9.5%). In total, 352/380 swabs were also analysed by PCR. In the IFA non-interpretable group, 273/283 were analysed by PCR. Of these, 75 were positive (27.5%) and 198 were negative (72.5%). Thirty four of the 36 IFA positive swabs were analysed by PCR. All were confirmed by PCR. In the IFA negative group, 45/61 were analysed by PCR. Three swabs were PCR positive and 42 were negative.

Conclusions: In this study, the performance of PCR was clearly superior to the IFA test that is routinely used for diagnosis of VZV infection on skin swabs. Especially, the number of uninterpretable results with IFA is unacceptably high. In this category, more than a quarter of the swabs produced a positive result by PCR, increasing the number of positive results as compared by IFA alone by more than 200%. Moreover, some additional positives were found in the IFA negative swabs. In Belgium, the IFA test is reimbursed by the national health ensurance system, while PCR on skin swabs is not. Therefore, switching the reimbursement to the most performing test should be considered.

P778 Evaluation of a new VIDAS® test for the detection of Epstein-Barr virus VCA IgG & IgM and EBNA IgG antibodies in human serum samples

L. Allard, A. Foussadier, P. Desmottes (Marcy l'Etoile, FR)

Objective: The aim of the study was to evaluate the performance of the 3 new automated VIDAS Epstein-Barr virus (EBV) reagents for the determination of the patient EBV serological characterised. The EBV reagents currently under development on VIDAS instrument are aimed to detect immunoglobulins against Viral Capside Antigen (VCA) and Epstein-Barr nuclear antigen (EBNA):VIDAS VCA IgG, VIDAS VCA IgM and VIDAS EBNA IgG

A comparison of the VIDAS EBV® tests was performed with EBV automated tests on the LIAISON® system (DiaSorin, Italy) using characterised sera samples.

Methods: VIDAS EBV VCA IgG and EBNA IgG reagents use specific EBV peptides coated on the solid phase to capture viral antigen immunoglobulins. The peptide-EBV IgG antibody complexes are later revealed using an anti-human IgG conjugated to Alkalin Phosphatase.

VIDAS EBV VCA IgM is based on immunocapture of serum EBV IgM. Twenty four sera from EBV primary infection, 20 sera from EBV past infection and 31 negative sera samples with a clinical status determined with the Immunofluorescence Gold Standard method (IF) were tested with the 3 VIDAS EBV markers to determine the performance. A concordance analysis between VIDAS and LIAISON was performed on an average of 75 samples on the 3 reagents. Discrepant results were analysed using IF.

Results: On defined IF characterised samples, the specificity of VIDAS VCA IgM, VCA IgG and EBNA IgG were 96.1%, 96.4% and 100% respectively and the sensitivity of VIDAS VCA IgM, VCA IgG and EBNA IgG were 100%, 95.6% and 100% respectively. For comparison, the specificity of LIAISON VCA IgM, VCA IgG and EBNA IgG were 98.0%, 96.4% and 97.6% respectively and the sensitivity of LIAISON VCA IgM, VCA IgG and EBNA IgG were 100%, 91.1% and 100% respectively.

Therefore, on this preliminary study VIDAS EBV overall performance leads to a more accurate clinical diagnosis of EBV primary infection than LIAISON EBV.

On random samples the concordance between VIDAS and Liaison VCA IgG, VCA IgM and EBNA IgG is 97.3%, 97.3% and 98.6%, respectively.

Conclusion: The new VIDAS EBV reagents presented good performance in accordance with the patients' serological status established with the IF. Evaluation on routine samples has also shown that VIDAS EBV reagents performed better than another automated test. VIDAS EBV reagents will be a good alternative to currently used manual method for MNI determination enabling single testing as well as series.

P779 Performance evaluation of VIDIA® CMV IgG assay, a new automated immunoassay for the detection and quantification of CMV IgG in human serum and plasma

F. Limonne, J. Dupret-Carruel, P. Desmottes (Marcy l'Etoile, FR)

Objective: The VIDIA system is a new automated, primary tube immunoassay instrument designed to reinforce traceability and simplify the daily workload for routine testing.

We evaluated the performance of VIDIA CMV IgG (bioMérieux) in terms of measuring range, precision, sensitivity, specificity. A correlation study with VIDAS CMV IgG was also performed.

Material and Methods: The VIDIA CMV IgG assay principle combines a two-step "ELISA indirect" immunoassay method with a final chemiluminescence detection. In the first step CMV IgG antibodies present in the sample bind with purified CMV Ag coated on the magnetic particles and with the anti-human IgG monoclonal conjugated with alkalin phosphatase (PAL) for the revelation phase.

The results of the tests are expressed in AU/ml (Arbitrary Unit). The positive cut-off was defined at 3 AU/ml, a grey zone is defined between 2 and 3 AU/ml and samples below 2 AU/ml are considered as negative. The study was performed by testing 60 positive and 43 negative samples. The serological status of the samples was established according to the results obtained with 3 CE-marked immunoassays: VIDAS CMV IgG (bioMérieux, France), CMV-IgG-ELA Test PKS medac (medac Diagnostika Germany), Enzygnost Anti CMV/IgG (Dade-Berhing, Germany).

Correlation with VIDAS CMV IgG was performed on 291 samples.

The study was done in the bioMérieux R&D laboratory during the development phase of the VIDIA CMV IgG reagent.
Results: With a measuring range up to 400 AU/ml, the precision obtained for samples at 10 AU/ml up to 250 AU/ml was between 4% and 12%, respectively.
Sensitivity and specificity were 100% on 103 samples tested.
Correlation coefficient between VIDIA CMV IgG and VIDAS CMV IgG was found at 0.89 and the concordance between the results of the 2 tests was 100%.
Conclusion: The very good concordance found between VIDIA CMV IgG and the status of the samples defined 3 CE-Marked tests, leads to a 100% sensitivity and specificity for the new VIDIA test under development. VIDIA CMV IgG is also well correlated with VIDAS CMV IgG and presents a good precision throughout the whole measuring range.
These first results show that VIDIA CMV IgG could adequately discriminate between IgG positive and negative samples, even if these results will have to be confirmed on the final commercialised product.

P780 Rapid and efficient detection of viral gastroenteritis by an automated multiplex real-time PCR approach

T. Schuurman, L. Gard, H.G.M. Niesters (Groningen, NL)

Objectives: Traditionally, viral gastroenteritis is diagnosed by antigen detection, electron microscopy, and increasingly PCR. However, this necessitates the use of separate assays for the different viruses. Multiplex real-time PCR (MPCR) provides an efficient alternative for diagnosis of viral gastroenteritis, especially when limited specimen is available In addition, it may be complemented by a similar approach for bacteria and parasites. In this study we compared our traditional detection methods to a 3-tube multiplex real-time PCR.
Methods: Stool specimens (n = 212) were obtained between July and December 2007 for routine diagnostics of gastrointestinal viruses at UMCG. Routine procedures consisted of antigen detection (astrovirus [hAsV], rotavirus [hRoV]), or singleplex real-time PCR (adenovirus [hAdV], enterovirus [hEV], norovirus genogroup I + II [hNoV], parechovirus [hPEV]). Nucleic acids were isolated by NucliSENS easyMAG specific A protocol (bioMérieux) using the phocin distemper virus (PDV) as internal control. Multiplex real-time PCRs included hAsV, hNoV, hRoV, PDV (Mplex 1), hEV, hPEV, PDV (Mplex 2), and hAdV, bocavirus (hBoV) (Mplex 3). Detection of hBoV was included to study its possible role in gastroenteritis.
Results: Fully concordant results were obtained by MPCR in 96.3% of tests requested. Positive specimens not detected by MPCR were exclusively specimens with low levels of viral RNA (Ct > 39), except for 1 clearly antigen positive hRoV. MPCR detected more hRoV (4/153), hPEV (8/185), and hAsV (1/135) in specimens negative by routine procedures. In addition, MPCR detected 3 positive hRoV infections in specimens with insufficient volume for antigen testing. Another 30/212 specimens tested positive for hAdV, and 7/212 for hBoV, although in the latter case, Ct values were always >35. Unresolved results due to inhibition were obtained for 3, 4, 6, and 3 specimens by routine PCR, Mplex1, Mplex2, and Mplex3 respectively.
Conclusion: MPCR provides a feasible alternative to separate routine diagnostics tests for detection of viral gastroenteritis. MPCR increased the sensitivity for hRoV and hPEV, although the sensitivity for hEV was slightly reduced. However, the clinical relevance of the infections missed by MPCR seems limited based on the high Ct values. Finally, the role of hBoV in the aetiology of viral gastroenteritis seems questionable based on the amount of hBoV DNA detected.

P781 Comparative evaluation of the NucliSENS easyMAG automated system for the extraction of viral DNA from whole blood samples: application to the monitoring of cytomegalovirus and Epstein-Barr virus loads

S. Pillet, T. Bourlet, B. Pozzetto (Saint Etienne, FR)

Objectives: Due to the high amount of genetic material in whole blood samples, the new extraction methods must be carefully evaluated by comparison to the reference techniques such as those using columns to recover correctly the nucleic acids used in amplification techniques. The aim of this study was to evaluate the ability of the NucliSENS easyMAG automated system (bioMérieux) using magnetic silica to extract viral nucleic acids from human whole blood for the determination of the viral load in patients suspected of cytomegalovirus (CMV) or Epstein-Barr virus (EBV) infection.
Methods: Two hundred microlitres of whole blood were extracted either by the manual Qiagen method (QIAamp DNA blood extraction kit) or by the "Specific B" protocol on the NucliSENS easyMAG instrument. CMV or EBV DNA was quantified by using the respective R-gene amplification kits (Argene). Ninety six samples (including 75 found initially positive in our laboratory) and 80 (59 positive) were selected for CMV and EBV analysis, respectively.
Results: A total agreement between the two extraction techniques was of 88.5% for CMV and 81.3% for EBV. The sensitivity of the NucliSENS easyMAG extraction method was 89.3% and 100% for CMV and EBV respectively; for comparison Qiagen extraction method exhibited a sensitivity of 82.6% and 83.1% for CMV and EBV respectively. As EBV tests, CMV tests were performed from same samples to compare the two extraction methods: the sensitivity difference with the conventional method used in our lab could be attributed to samples storage. For samples found positive after extraction by both methods, the correlation coefficient (r test) between the viral loads was 0.855 for CMV and 0.942 for EBV; the mean between the difference in viral loads was –0.00859 log copies/mL for CMV (not statistically significant) and 0.22 log copies/mL for EBV to the benefit of the automated extraction method ($p < 0.001$).
Conclusion: The excellent concordance between the results obtained after using both extraction methods validates the capacity of the "Specific B" protocol to extract viral DNA from whole blood with the NucliSENS easyMAG system in two models measuring viral load. A trend was noted for a better sensitivity of NucliSENS easyMAG regarding the low values. The additional advantages of this automated extraction technique include: reduction of technical time (2/3) and of cross-contamination avoiding centrifugation, and improvement of standardisation, traceability and quality control assessment.

P782 Evaluation of a new immunochromatography test for the detection of Norovirus

D. Kato, Y. Nakayama, H. Tajiri, T. Tanaka, Y. Hirayama, K. Kamata, S. Sekine (Tokyo, Nagano, Osaka, JP)

Objectives: Norovirus is one of the most common pathogens causing gastroenteritis and belongs to the family Caliciviridae, which is a non-enveloped, positive-sense, single-stranded RNA virus. RT-PCR and ELISA are widely used detection methods, which have drawbacks such as long turnaround times, relatively high cost, need for specialised equipment and trained technicians. The newly developed Quick Ex-Norovirus "SEIKEN" assay is based on immunochromatography (IC) method, which is easier to perform, rapid, cost efficient and offers true clinical value.
Materials and Methods: A total of 163 faecal specimens obtained from adults, children and infants in Japan, who showed acute gastroenteritis symptoms during period May 2006 to March 2007, were collected and stored in a public laboratory and two hospitals in Japan.
The reactivity of this test was evaluated against Virus-like particles (VLPs), containing 6 genotypes of genogroup 1 (G1) and 13 genotypes of genogroup 2 (GII).

The test was performed according to the instruction manual. In summary, 0.1 g of faecal specimen (or 100 μL of VLPs) was added to the specimen preparation tube, containing 0.9 mL of specimen buffer, then mixed with a tube mixer for 30 sec. and centrifuged at 2000xg for 5 min. An aliquot of 300 μL of supernatant was transferred to a sample tube and after capping this tube with a specimen filter, filtrate is collected into a reaction tube. The IC test strip was inserted into this tube and interpretation was done after 15 min. incubation time at room temp. All clinical specimens were also tested by RT-PCR, as described by Yan et al. (2003). A primer set of G1-SKF and G1-SKR was chosen for G1 and a set of G2-GKF and G2-SKR for GII identification.
Results: Fifty three (53) of 163 samples (32.5%) were positive by the IC test. Sensitivity, specificity and overall agreement were 73.6%, 98.9% and 87.7% respectively, when compared with RT-PCR. Nineteen (19) specimens were negative by the IC test, but positive by RT-PCR. These discrepancies might be due to low viral load in these specimens. The IC test showed positive against all VLPs, including GI types 1, 2, 3, 4 & 6 and GII types 1 to 8, 12 to 15 and 17.
Conclusion: The sensitivity and specificity of the IC test for clinical specimens were comparable with current Norovirus detection methods, hence the Quick Ex-Norovirus "SEIKEN" assay might be a valuable attribute in the clinical setting.

HIV – Therapeutics

P783 Neoplasia in patients with HIV infection: effect of HAART

C. Asencio, J.L. Puerto, J.L. Andrey, A.A. Garcia-Egido, M.A. Escobar, S.P. Romero, J.A. Bernal, J. Gonzalez-Outon, F. Gomez (El Puerto Santa Maria, ES)

Surveillance data indicate that, the incidence and type of HIV related neoplasias has changed after the introduction of HAART.
Objective: To determine the incidence and types of cancers in the pre-HAART and post-HAART eras, and the differences between women and men.
Methods: Retrospective record review of HIV infected patients with cancer from January 1991 to December 2003 at a teaching hospital.
Results: A total of 268 HIV patients with cancer were identified, 206 men (age: 38±11 years, CD4: 123±39/μL) and 62 women (age: 44±16 years, CD4: 68±27/μL), of them 90 were detected in the pre-HAART (33.6%) and 178 in the post-HAART era (66.4%, p=n/s). AIDS defining cancers (Total: 215, 72.4%; of them 108, 77.7% in men vs. 31, 22.3% in women) were more frequent pre-HAART (Total: 76, 54.7%; of them 60, 43% in men vs. 16, 11.5% in women) than post-HAART (Total: 63, 45.3%; of them 48, 34.5% in men vs. 15, 10.8% in women). Non AIDS defining cancers (Total: 53, 27.6%; of them 34, 64% in men vs. 19, 36% in women) were less frequent pre-HAART (Total: 14, 26.4%; of them 9, 17% in men vs. 5, 5.3% in women) than post-HAART (Total: 39, 73.6%; of them 25, 47.2% in men vs. 14, 26.4% in women). Total cancer related mortality was higher pre-HAART (61% vs 52%, $p < 0.05$) and in women (60% vs 55%, p=n/s) than post-HAART (Total: 53, 27.6%; of them 36, 18.8% in men vs. 17, 8.9% in women). AIDS defining cancer related mortality was higher pre-HAART (65.8% vs 36.5%, $p < 0.01$) in both sexes ($p < 0.01$), while non AIDS defining cancer related mortality was higher post-HAART (76.9% vs 35.7%, $p < 0.01$) in both sexes ($p < 0.01$).
Conclusions: The incidence of non AIDS defining cancer increased, although the total incidence of HIV related neoplasia has not changed after HAART. Total cancer related mortality is higher pre-HAART and in women. Both sexes have a higher mortality by AIDS defining cancer pre-HAART and, by non AIDS defining cancer post-HAART.

P784 Influence of anti-retroviral treatment on gastric secretion, *Helicobacter pylori* colonisation of gastric mucosa and fungal colonisation of upper gastrointestinal tract in HIV-infected patients

P. Skwara, A. Ciesla, I. Sobczyk-Krupiarz, M. Bociaga, A. Kalinowska-Nowak, T. Mach (Cracow, PL)

Objectives: HIV infection is considered to have negative influence on gastric acid juice secretion and results in higher prevalence of fungal colonisation of upper gastrointestinal (GI) tract, whereas *Helicobacter pylori* (Hp) prevalence in stomach seems to be lower in HIV-infected patients (pts). The aim of the study was to estimate influence of antiretroviral treatment (HAART) on gastric secretion, Hp colonisation of stomach and fungal colonisation of upper GI tract.
Methods: 94 HIV-infected pts were studied, half of them had CD4 lymphocyte count <200/uL. 9 of 21 pts receiving HAART belonged to this group. Biopsy samples were taken during endoscopy from corpus and antrum of stomach to confirm presence of Hp by histological analysis and rapid urease test. Quantitative mycologic cultures from oral and oesophageal swabs were analysed in 70 pts. Gastric secretion was evaluated in 37 pts using Kay method on the basis of BAO, MAO and PAO. The results were compared to HIV viral load (VL) detected by PCR.
Results: VL decrease correlated with increased BAO (correlation coefficient r=-0.165), MAO (r=-0.287) and PAO (r=-0.289) and decreased BAO/MAO ratio (r=0.22). Prevalence of Hp in pts on HAART in comparison to the rest of pts, was lower in both corpus of stomach (28%vs48%) and antrum (38%vs62%) /$p > 0.05$/. Hp was present in corpus and antrum (respectively) in 29%/47% of pts with VL < 500 copies/mL and 44%/49% of pts with higher VL /$p > 0.05$/. Fungal colonisation rate in pts on HAART (vs the rest of pts) was lower in both oral cavity (64%vs87%) and oesophagus (64%vs84%) /$p > 0.05$/. Lower prevalence of fungal colonisation in pts with VL < 500 copies/mL (vs the rest of pts) was found in oral cavity (67%vs90%) /$p > 0.05$/ and oesophagus (58%vs87%) /$p < 0.05$/.
Conclusions: Inhibited HIV replication due to antiretroviral therapy results in increase in gastric secretion, as well as decrease in fungal colonisation of the upper GI tract and Hp colonisation of stomach.

P785 Liver toxicity and plasma drug levels of lopinavir in HIV/HCV co-infected patients according to the degree of liver fibrosis

J. Moya, J.L. Casado, A. Moreno, L. Aranzabal, C. Gutierrez, M. Perez-Elias, S. Moreno (Madrid, ES)

Objectives: HCV co-infection is a well known risk factor for developing hepatotoxicity in HIV-infected patients receiving HAART. However, few data exist about liver toxicity with r/lopinavir and the influence of plasma drugs levels, especially in patients with different stages of HCV disease.
Methods: Prospective cohort study of 51 HIV/HCV co-infected patients who underwent a liver biopsy and who received lopinavir as the third drug regimen. Liver fibrosis was staged using a scoring system of 0 (no fibrosis) to 4 (cirrhosis). Hepatotoxicity was defined as an increase in AST/ALT levels over five times the upper limit of normal, or a 3.5-fold increase if baseline levels were abnormal, with or without clinical symptoms of liver toxicity. Plasma through levels of lopinavir were determinated by HPLC in all the cases.
Results: Mean age was 41 yrs, 73% were male, and 73% were former IDUs. Of note, 58% of patients had a prior diagnosis of AIDS. Mean estimated time of HCV infection was 17.6 yrs, mean HCV viral load was 1.298235 UI/ml, and the predominant HCV genotypes were 1 and 3. Median plasma drug levels of lopinavir were 7315 ng/ml (638–11206), with differences according to the stage of fibrosis (8114, 6614, 6008, and 4412 ng/ml for fibrosis stage 1 to 4, respectively). Notably, in three cirrhotic patients with an advanced stage of disease (MELD scale >11), median plasma through levels were 881 ng/ml. During an accumulated time of 461 months on r/lopinavir therapy, there were 5 cases of hepatotoxicity. In these patients, plasma trhough levels of lopinavir were

similar to those observed in patients not developing toxicity (6502 vs 7368 ng/ml).
Conclusions: The risk of liver toxicity was very low in HIV/HCV co-infected patients receiving r/lopinavir. In these patients, plasma drug levels of lopinavir showed high interpatient variability and were not associated with toxicity.

P786 Dream changes after efavirenz treatment

M. Velasco, J. Pareja, J. Losa, A. Espinosa, J. Valverde, A. Delgado-Iribarren (Madrid, ES)

Objective: Although sleep disturbance is a frequent side effect of efavirenz, there is no studies about abnormalities in the quality of dreams.
Method: This is a pilot study. HIV patients without neuropsychiatric diseases underwent a polisomnography (PSG) study before and after efavirenz treatment. Efavirenz plasma levels were assessed before the second (PSG). Patients were awoke at first REM sleep period during the night and at REM sleep period occurring after 5:00 am and invited to tell the dream. Dream changes were evaluated by recall rate, number of thematic units and emotional content classified into four categories: violent/highly anxious, moderately anxious, pleasant and neutral. Dream length was assessed by the number of words included in the description. Chi square, Student T test and Z signs test were used to compared results.
Results: Eighteen PSG were performed in ten patients. Second PSG was performed after 10.4 (SD 5.4) days of efavirenz treatment with all patients having therapeutic efavirenz plasma leves (>1 μg/ml). Dreams were recalled in 84% before efavirenz and 43% after efavirenz (p = 0.024). There were no differences in the mean number of words per dream before and after efavirenz treatment (61.96 versus 47.5, p = 0.115) neither in the number of thematic units (16 versus 6, p = 0.442). There were less anxious and violent dreams after efavirenz (3 versus 1). The proportion of dreams with no neutral emotional content (either pleasant or unpleasant) was 37.5% before efavirenz and 66.7% after efavirenz treatment (p = 0.046).
Conclusions: Efavirenz treatment increases the proportion of no neutral dreams in this group of patients. There were no longer dreams and no more dreams with negative emotional content after efavirenz treatment. Dream recall was lower after efavirenz treatment. Further studies in this area are needed.

P787 Improved long-term survival among AIDS patients with progressive multifocal leukoencephalopathy receiving potent antiretroviral therapies

J. Garcia-Garcia, J.L. Casado, I. Corral, A. Moreno, F. Dronda, M.J. Perez-Elias, J. Peris, S. Moreno (Madrid, ES)

Objective: To determine the outcome of progressive multifocal leukoencephalopathy (PML) in patients with AIDS.
Methods: A retrospective cohort of 52 subjects with AIDS who were diagnosed of PML (clinical and neuroradiological findings of active PML, no other aetiology, and/or PCR detection of JCV DNA in CSF, and/or histopathological findings in biopsy) from 1996 to 2007.
Results: At diagnosis, the median CD4+ cell count and plasma HIV RNA level were 93/mL (range, 7–410/mL) and 4.8 log copies/mL (2–5.7), respectively. A probable immune reconstitution inflammatory syndrome (IRIS), defined as new onset (<180 days) of symptoms shortly after initiation of HAART, was described in 10 cases (19%). As expected, patients with IRIS had higher CD4+ count (181 vs 117/mL) and a lower HIV RNA level (2.95 vs 4.6 log copies/mL, p = 0.002) at the time of diagnosis. JCV DNA was detected in 52% of cases, and, of note, the CD4+ count was higher in patients presenting with a negative value (156 vs 113/mL). Moreover, JCV in CSF was mostly detected in patients without IRIS (57 vs 33%). During a median follow-up of 745 days, a total of 14 patients died (27%), most of them during the first 3 months after diagnosis (13 out of 14 cases, 93%). The probability of survival was 90% and 70% at 24 weeks for patients with or without IRIS, respectively (p = 0.15, log-rank test). There was no association between initial CD4+ count and mortality (28% vs 25% for patients below or above a CD4+ count of 100/mL). At the end of follow-up, HIV viral load was <50 copies/ml in 64% of cases, and CD4+ cell count was 357/mL, without differences according to initial response.
Conclusions: The prognosis of PML in patients with AIDS receiving potent antiretroviral therapies has improved significantly, and, for patients surviving three months after the diagnosis, the outcome is similar to that observed in the HIV population. IRIS diagnosis was not associated with a worse outcome.

P788 Safety and efficacy of a fixed-dose combination of zidovudine, lamivudine, and nevirapine in antiretroviral-naive and –experienced HIV-1 infected patients

S. Sungkanuparph, S. Kiertiburanakul, B. Piyavong, W. Manosuthi, K. Malathum (Bangkok, Nonthaburi, TH)

Objectives: To evaluate the safety and efficacy of a fixed-dose combination (FDC) of zidovudine, lamivudine, and nevirapine (AZT/3TC/NVP) which has recently been available in developing countries and is planned to replace the extensive use of the FDC of stavudine, lamivudine, and nevirapine (d4T/3TC/NVP).
Methods: A cohort study was conducted in HIV-1 infected patients who were initiated FDC of AZT/3TC/NVP as an initial antiretroviral therapy (ART) or as switching ART from other stable regimens at a medical-school hospital in 2006. Patients were followed up for 12 months and were categorised into initial ART and switching ART groups.
Results: A total of 241 patients were included; 62% were male and mean (SD) age was 40.4 (8.7) years. Mean (SD) body weight and hemoglobin were 60.2 (11.3) kg and 13.4 (1.8) g/dl, respectively. Of 241 patients, 51 were in initial ART group and 190 were in switching ART group. In initial ART group, median (IQR) baseline CD4 cell count and plasma HIV-1 RNA were 159 (70–210) cells/mm^3 and 5.4 (4.6–5.9) log copies/ml, respectively. In switching ART group, median (IQR) baseline CD4 cell count was 386 (276–519) cells/mm^3 and all had plasma HIV-1 RNA <50 copies/ml. Of 190 patients, 184 (97%) switched from NNRTI-based regimens and 116 (61%) were FDC of d4T/3TC/NVP. Median (IQR) duration of ART prior to switching was 34 (22–51) months. By intend-to-treat analysis, 78% in initial ART group and 91% in switching ART group had plasma HIV-1 RNA <50 copies/ml at 12 months of FDC of AZT/3TC/NVP. At 6 and 12 months, median CD4 cell count significantly increased from baseline to 303 (p =0.030) and 352 (p < 0.001) cells/mm^3 in initial ART group; 415 (p = 0.026) and 436 (p = 0.018) cells/mm^3 in switching ART group. During 12-month follow-up period, 14% and 6% of patients in initial ART group and switching ART group, respectively, had discontinued FDC of AZT/3TC/NVP due to adverse events. These adverse events (initial ART, switching ART) included anaemia (4%, 3%), rashes (6%, 0.5%), nausea/vomiting (4%, 1%), hepatitis (2%, 0%), myalgia (0%, 0.5%), and non-improved lipodystrophy (0%, 0.5%).
Conclusions: A FDC of AZT/3TC/NVP has good safety and efficacy for using as initial ART in antiretroviral-naive patients and for switching ART in patients with stable ART and complete viral suppression. The virological and immunological outcomes are favourable. In resource-limited settings, a FDC of AZT/3TC/NVP is an alternative for replacing a FDC of d4T/3TC/NVP.

P789 Tolerance and quality of life improvements: Kaletra® soft-gel capsules vs Kaletra® tablets: the KaleVie study

N. Terrail, S. Guessant, H. Akkari, L. Michel, B. Laribii, L. Guillin, A. Becker, S. Hansel-esteller (Montpellier, Paris, Perpignan, FR)

Background: Kaletra® tablets were introduced in september 2006 in France to replace soft gel capsules (SGC) with no need for refrigeration or dosing with food, and a new excipients formulation. The aim of this study was to evaluate in real life the tolerance, the change of comfort of drug intake, and quality of life between the end of the last month on SGC (M0) and the first month on tablets (M1).

Methods: From september 2006 to february 2007, an open investigation, multicentre prospective study was conducted on HIV patients (pts) switching from Kaletra® SGC to tablets to compare the course of comfort of drug intake, quality of life, confidentiality, with or without food intake, preservation of drug, tolerance, and impact of new tablet formulation on everydaylife between M0 and M1.

Results: 81 pts were included (59 males, 22 females); mean age: 44 (29–77 years). Seropositivity detections dated back to 11 years (1 month – 21 years). Mean duration of antiretroviral treatment was 9 years: 2 years on Kaletra® (1 month – 6 years).

Comfort of drug intake evaluated on a 0 to 10 graduated scale went up from 7.9 to 8.6 ($p < 0.05$), and 73% at M1 compared to 64% at M0 did not have quality of life affected with HIV infection and treatment. Removing food restrictions was very important for 50% of pts; no need for refrigerate upgraded confidentiality for 65% of pts and was considered as very important for 94%. Food intake with SGC or tablets increased gastro-intestinal tolerance in 75% pts. Diarrhoeas and gas were less frequent and severe when switching to tablets ($p < 0.05$) and were not more associated with a regimen including AZT ($p > 0.05$) or a first month of Kaletra© treatment ($p > 0.05$). There was less dislike with the yellow tablets than orange SGC ($p < 0.05$). Observance did not increase ($p > 0.05$) but no patient encountered any confidentiality problem leading to miss an intake and 23% had the feeling tablets were more efficient; 18% declared they would change their travel habits at M1.

Conclusion: Following switch from SGC to tablets, subjects reported an increased quality of life and confidentiality, and a better tolerance. Food intake lowered gastro-intestinal adverse events with either SGC or tablet formulation.

P790 Efficacy and safety of filgrastim in HIV/AIDS patients with bacterial infections

T. Tsertsvadze, L. Sharvadze, N. Gochitashvili, M. Karchava (Tbilisi, GE)

Background: To assess the effect of filgrastim (G-CSF) in HIV/AIDS patients with bacterial infections with or without neutropenia since it is supposed that filgrastim, together with increase of neutrophil count, can also enhance their functional activity and thus improve outcome of bacterial disease.

Methods: 48 HIV/AIDS patients with severe bacterial infection/sepsis aged 19–60 (study group) were enrolled in the randomised controlled, open-label, prospective follow-up study. Among them 29 patients were neutropenic with absolute neutrophil count (ANC) $<1.0\times10^9$/l, and 19 were non-neutropenic. Patients in the study group were treated with standard therapy (antimicrobial drugs and symptomatic treatment) and filgrastim 5 μg/kg daily for 5–7 days. In control group were included 17 HIV patients with severe bacterial infection or sepsis with (9 patients) or without (8 patients) neutropenia on standard therapy without filgrastim. Functional activity of neutrophils was measured by nitroblue tetrazolium reduction (NBT)-test.

Results: As neutropenic so non-neutropenic filgrastim-treated patients required fewer hospital days for infections and fewer days of intravenous antibacterials compared to control group; death and relapse rate was less frequent in patients with filgrastim. Severe neutropenia was less frequent in neutropenic patients with filgrastim compared to control patients. NBT-test showed improved neutrophil's functional activity in filgrastim-treated patients. Filgrastim was not associated with increase in HIV plasma RNA level or any new or unexpected adverse events.

Conclusions: Filgrastim was safe and effective for severe bacterial infection/sepsis in HIV/AIDS patients with or without neutropenia. Filgrastim was well tolerated by patients and significantly improved the patient's quality of live. It may reduce the duration of infections, hospital days for infections, days of intravenous antibacterial agents and risk of relapse. Filgrastim treatment was also associated in improved neutrophil functional activity.

Further studies are required to optimise treatment regimen.

P791 Pharmacokinetics of lopinavir combined with rifabutin in a clinical setting

S. Carbonara, A. Matteelli, M. Regazzi, P. Villani, E. Ciracì, A. Carvalho, I. El-Hamad, M. Cusato, C. Tinelli, L. Monno (Bari, Brescia, Pavia, IT)

Background: The use of ritonavir-boosted lopinavir (LPV/r) plus adjusted dose rifabutin (aRFB) is currently allowed in HIV-infected subjects with mycobacterial disease (MD). This study investigated the pharmacokinetic (PK) parameters of LPV/r when associated with aRFB in a clinical setting, from which no such data have been published thus far.

Methods: This prospective, multicentre study enrolled consecutive HIV-infected subjects with MD for whom clinicians chose a combination regimen including LPV/r (standard dose)+aRFB (150mg 3x/week), associated with any anti-mycobacterial (AMB) drugs and no antiretroviral (ARV) drugs other than nucleos(t)ide reverse transcriptase inhibitors. Treatment adherence was supervised. A 12-hour PK assessment of plasma LPV levels was performed on ⩾1 occasion after >14 days of LPV/r+aRFB administration and, when feasible, after >14 days of RFB withdrawal. LPV plasma levels were centrally assayed by a validated HPLC-UV method (lower quantification limit 50ng/mL). PK parameters were calculated by standard non-compartmental methods (KINETICA, version 4, InnaPhase). Intra-subject changes in PK parameters were evaluated by calculating geometric mean ratios (GMR) and 95%CI (SAS).

Results: LPV PK parameters were obtained in 25 subjects during aRFB co-administration: median age 40 years (range 27–54), weight 61Kg (42–77), males 72%, Caucasian 64%, black 20%, other races 16%, HVC or HBV co-infection 32%, liver impairment 24%. MD was tubercular in 64%, non tubercular (24%) and undefined (12%). Mean±SD LPV Ctrough and Cmax were 11.3±5.1 and 18.7±6.9 μg/mL, respectively. AUC0–12h was 166.2±63.4 μg.h/mL and CL/F 0.05±0.02L/h/kg. LPV PK assessments in absence of RFB were also available for 6/25 patients. The GMR (95%CI) of LPV CL/F/Kg, Ctrough, Cmax and AUC0–12h when associated with aRFB versus alone were 1.17 (0.66–2.07), 0.84 (0.40–1.77), 0.80 (0.47–1.37) and 0.88 (0.44–1.76), respectively.

Conclusions: Mean LPV Ctrough and AUC0–12 during aRFB co-administration in our clinical population were well above the minimum recommended target levels (even those recommended for antiretroviral experienced patients). LPV showed a non-significant intra-patient mean increase in CL/F (17%) when associated with aRFB versus alone; however, this finding evidenced a high inter-subject variability, probably determined by the different patient characteristics which emphasizes the usefulness of therapeutic drug monitoring during AMB-ARV combination treatments.

Nosocomial outbreaks

P792 Cross-transmission of a multidrug-resistant *Acinetobacter baumannii* clone produced endemic nosocomial bacteraemia and one outbreak in a Mexican Hospital

M.D. Alcantar-Curiel, R. Morfin-Otero, M.D. Jarillo, E. Rodriguez-Noriega, J.R. Araiza, B.E. Real, C. Gayosso, J.I. Santos, C.M. Alpuche-Aranda (Mexico City, Guadalajara, MX)

Background: Multidrug-resistant *Acinetobacter baumannii* (Aba) has emerged as an important cause of endemic nosocomial infections and epidemic outbreaks.

Objectives: To describe the antimicrobial susceptibility profile associated to genotyping of Aba causing nosocomial infections and outbreaks in one Mexican Hospital.

Methods: This is a descriptive molecular epidemiology study performed in a 1,000-bed tertiary care University Hospital in Guadalajara, Jalisco, Mexico. From December 2002 to August 2007, one hundred Aba isolates from nosocomial infections were detected from several wards in Hospital Civil de Guadalajara. Clinical data were collected from medical records. Antibiotic susceptibility testing was performed by disc diffusion method

according to CLSI guidelines. Clonal analysis was determined by ApaI – Pulsed Field Gel Electrophoresis (PFGE).

Results: Sites of isolation included: Skin and soft tissue (46%), bloodstream (42%), sterile fluids (8%), and respiratory tract (4%). All Aba isolates were resistant to all quinolones, aminoglycosides, and β-lactam antibiotics, with 50% resistance to carbapenems. Genetic fingerprinting by PFGE of these isolates showed extensive heterogeneity between isolates, although one major cluster involving 37 patients belonged to a single clonal type. This Aba clone was an endemic in 2005 and 2006, and produced an outbreak in 2007. This clone was detected in the majority of the hospital wards.

Conclusions: Proper control of this multidrug-resistant Aba will require a multidisciplinary approach, including identification of resistance mechanisms, optimising antibiotic use based on local epidemiology and vigorous implementation of infection control procedures.

P793 Spread of multidrug-resistant *Acinetobacter baumannii* in intubated patients

E. Alp, M. Yerer, S. Kocagöz, G. Metan, D. Esel, Y. Gurol, M. Doganay (Kayseri, Istanbul, TR)

Objectives: *Acinetobacter baumannii* constitutes one of the most common cause of ventilator associated pneumonia in intensive care units. The colonised patients are important source for environmental contamination and patient-to-patient spread of microorganism. The major mode of transmission from patient-to-patient and environment-to-patient is contaminated hands of healthcare workers. The aim of this study was to determine the risk factors for the colonisation of respiratory tract and infection with *A. baumannii* in medical ICU (MICU) and examine the genetic relatedness of the strains to show the spread of isolates.

Methods: This study was conducted prospectively between December 1, 2004 and January 31, 2006 in MICU. Patients (>16 years) admitted to the MICU and mechanical ventilated and/or intubated were enrolled in the study. Endotracheal aspirate of these patients were screened for *A. baumannii* at the beginning of intubation (in the first 48 hours), at the end of first week and at the time of withdrawal of endotracheal tube. Patients intubated shorter than 48 hours were not included into the study and data of *A. baumannii* colonised or infected patients at ICU admission were not evaluated for the risk factors. Strains isolated from colonised and infected patients were evaluated for genetic relatedness. Genotyping analysis was performed by pulsed-field gel electrophoresis (PFGE)

Results: Ninety-eight patients were evaluated for *A. baumannii* colonisation during or at the end of their entubation and 44 (45%) of these patients were colonised with *A. baumannii*. The mean time for *A. baumannii* acquisition was 7.46±3.74 days (range 2 to 16 days). The length of entubation (OR:1.032, p: 0.014) and diabetes mellitus (OR:4.140, p:0.008) were found to be the major risk factors for the colonisation of respiratory tract with *A. baumannii*. During the study period, *A. baumannii* infection developed in 35 (80%) of 44 colonised patients. The important risk factors for infection were *A. baumannii* colonisation (OR:3.962, p:0.006) and tracheostomy (OR:4.857, p:0.001). Genotyping analysis was performed for 59 isolates. Overall, three clones (clone A, B, C) were determined from patients, whereas 88% belonged to clone A (52 isolates), 7% clone B (four isolates) and 5% clone C (three isolates).

Conclusion: This study showed the spread of *A. baumannii* in intubated patients in a ICU with inadequate infrastructure.

P794 Risk factors for nosocomial *Acinetobacter* bacteraemia: a case-control study of intensive care unit patients

O. Tunger, G. Keles, C.B. Cetin, H. Gazi, S. Coban, I. Aras, M. Sakarya (Manisa, TR)

Objectives: This study was performed to identify risk factors and to determine the attributable mortality and outcome of *Acinetobacter* bacteraemia in intensive care unit.

Methods: A retrospective case-control (1:1) study was conducted in a tertiary, academic hospital, with 300 beds. From January 2001 to December 2006, 54 cases and 54 controls were included. Cases were all the true nosocomial bacteraemias by *Acinetobacter* spp. A control was defined as the consecutive patient with negative blood cultures, matched by sex, age (±10 years), primary and secondary diagnosis, APACHE II score (±2 points), operative procedures, and date of admission. Characteristics and mortality rates of patients with *Acinetobacter* bacteraemia and their controls were compared. The results were analysed using SPSS (version 11.0) for Windows.

Results: The mean age was 51.05±22.30 years (median = 56) for the cases, and 47.90±20.58 years (median = 44) for the controls. There was a trend for a longer median duration of hospitalisation among case patients, compared with control patients (33.31±30.67 versus 11.55±10.50 days; p = 0.06). Patients with *Acinetobacter* bacteraemia had significantly more hemodynamic instability (hypoxia, shock) and longer length of ventilator requirement than controls. Case-patients were more likely than controls to have had central venous catheter, peripheral arterial catheter, mechanical ventilation and total parenteral nutrition ($p < 0.05$). Thirty-three (61.1%) of the case patients died, compared with 14 (25.9%) of the control patients (p = 0.001). Attributable mortality is determined by subtracting the crude mortality rate of the controls from the crude mortality rate of the cases. The attributable mortality was 35.2%.

Conclusion: In critically ill patients *Acinetobacter* bacteraemia is associated with a significantly increased mortality rate.

P795 Role of tigecycline in the control of outbreak of carbapenem-resistant *Acinetobacter baumannii* infections in an intensive care unit, Kuwait

V. Rotimi, W. Jamal, M.I. Salama, K. El-Din, N. Dehrab (Safat, Jabriya, KW)

Objective: To report 3 different episodes of nosocomial outbreaks of multi-resistant *Acinetobacter baumannii* (MRAB) infections in an ICU setting, successfully controlled with tigecycline.

Methods: The outbreaks of *Acinetobacter* infections occurred in February and April, 2006 and April 2007. Patients' ages, nationality, underlying co-morbidities, prior antibiotics used, site of infection, major reason for hospital admission, whether or not ventilated and length of ICU stay, were recorded. Samples of endotracheal tube (ET) secretions, sputum, blood, urine, CSF and wound were collected and cultured on appropriate bacteriological media. The isolates were identified using automated VITEK 2 ID system and the API 20NE system. Susceptibility testing was done by the Etest method. Molecular typing of the isolates was determined by PFGE. Patient and environmental screening strategies previously agreed to by the Outbreak Management Committee were carried out. Patients were nursed in isolation rooms or single side rooms.

Results: A total 21 patients, aged 19–75 years, were involved. Time of admission to time of acquiring infection ranged from 3–31 days. All isolates were resistant to 15–17 antibiotics, including carbapenems (MRAB-C) but susceptibile to tigecycline with MIC90 of 2 μg/ml. Overall mortality rate was 14.3%. The first outbreak involved 6 cases with pnuemonia, meningitis and UTI. Time to clearance of the MRAB-C after therapy with amikacin and ciprofloxacin was 8.3 days and was associated with a mortality rate of 50%; tigecycline was unavailable for use at this time. The second outbreak involved 10 patients (6 bacteraemias, 3 pneumonia and 1 UTI). All patients received tigecycline in adequate doses. Time to clearance was 2.8 days and all survived. Five patients (3 bacteraemias, 1 pneumonia and 1 abscess), were involved in the third outbreak. They were also treated with tigecycline. Time to clearance was 3.1 days and all survived. Environmental screening revealed gross contamination of many surfaces and equipment within the unit. Genotypic characteristics demonstrated 2 distinct clonal strains. Other measures included closure of the ICU to new admissions during the second outbreak to allow for adequate cleaning and disinfection of the unit.

Conclusion: Two clones of MRAB-C were responsible for the outbreaks and successful control included the use of tigecycline and aggressive infection control strategies.

P796 An outbreak of multidrug-resistant *Acinetobacter baumannii* colonisation and infection in a neonatal intensive care unit of a major paediatric university hospital in Athens, Greece

E. Petridou, J. Papavasiliou, H. Kirikou, A. Charisiadou, P. Fratzaki, S. Photopoulos, K. Xerakia, A. Pangalis (Athens, GR)

Objective: The aim of this study was to investigate and report the epidemiologic, bacteriologic and clinical features of an outbreak caused by *A. baumannii* in a Neonatal Intensive Care Unit (NICU)

Materials and Methods: During a 10 month period, from October 2006 to July 2007, 180 infants were hospitalised in a 20 bed NICU. Surveillance cultures of nasopharyngeal and anal swab specimens were performed regularly to every neonate admitted to the NICU, and every 2 weeks until their discharge. Twenty two infants were colonised by *A. baumannii*. The isolated strains of *A. baumannii* were identified and tested for antibiotic susceptibility by VITEK 2 automated system (Biomerieux, France). The results of sensitivity tests were evaluated according to CLSI recommendations. The isolates proved to be resistant to aminoglycosides, cephalosporins, penems, co-trimoxazole and ciprofloxacin and sensitive only to colimycin, doxycycline and tetracycline. Five of those neonates developed bacteraemia and one of them died from sepsis. Environmental surveillance did not reveal the *A. baumannii* source. Epidemiological investigation revealed that acinetobacter entered the NICU in October with a colonised neonate coming from a maternity Hospital in a distant area where the microorganism was abundant. The infection control committee of the hospital reinforced the usual preventive measures as cohorting of the the colonised/infected neonates and especially the proper hand hygiene protocol among healthcare workers in order to control the outbreak. *A. baumannii* disappeared from NICU after the discharge of the last colonised neonate.

Conclusions: Outbreaks of multi resistant bacteria is a major problem in NICU because of the prematurity of neonates, the consumption of antibiotics, the use of invasive devises and the prolonged hospitalisation. Surveillance cultures, followed by a good medical practice and standard hygienic precautions should be stressed out.

P797 *Burkholderia* spp. contamination detected in ultrasound gels

M. Eyigor, G. Evcil Celik, B. Gultekin, N. Aydin (Aydin, TR)

Objectives: Contamination of pressure transducers, propofol, water used to dilute alcohol including skin antiseptics, mouthwash, antiseptics, etc has resulted in outbreaks of nosocomial infections. Similarly, there are also reports stating that contaminated ultrasound gels cause hospital infections. In this study, *Burkholderia* spp. contamination determined in ultrasound gels used in our hospital were investigated.

Methods: During surveillance studies performed for infection control in our hospital, an increase in wound infection rates were determined and environmental cultures were performed to determine the source of infection. In ultrasound gels, *Burkholderia* spp. was grown. Therefore, all gels in the hospital were collected to investigate for contamination. Gels were packed in boxes containing 12 plastic bottles, and inoculations into blood agar and EMB agar for culture were performed. Bacteria grown in cultures were defined by conventional methods and BBL Crystal Identification System (Becton Dickinson and Company). In order to investigate relationship with clonality, pulse-field gel electrophoresis was performed in identified origin.

Results: Two different brands of gels were found to be used in our hospital. A total of 669 unopened bottles of gels from two brands were sampled for cultures. When no growth was observed in any of total 364 bottles for one of the brands, these gels were distributed back to the hospital. As for the other brand, a total of 305 bottles were investigated and in 222 (72.8%) of them, similar colony growth was detected. One strain was taken per packet therefore total of 21 strains of *Burkholderia* spp., were defined. Pulse gel electrophoresis was performed for all 21 strains and was found that all originated from the same clone.

Conclusions: It should be considered that ultrasound gels may be contaminated during production and/or packaging and may be a source of nosocomial infections.

P798 Pseudo-outbreak of *Serratia marcescens* in a tertiary care hospital

D. Dundar, M. Meric, H. Vahaboglu, A. Willke (Kocaeli, TR)

Objectives: To investigate an outbreak due to *Serratia marcescens* isolated from different samples (mostly cathether tips) of the patients.

Methods: Between September and November 2007, an apparent increase in positive culture results for *S. marcescens* was observed in the Clinical Microbiology Laboratory of Kocaeli University Hospital. A pseudo-outbreak was suspected and an outbreak investigation including retrospective and prospective studies using chart review, environmental sampling and random arbitrary polymorphic DNA-polymerase chain reaction (RAPD-PCR) of randomly selected isolates were performed by Infection Control Commitee.

Results: During the epidemic period, 67 strains of *S. marcescens* were isolated from the various specimens of both hospitalised and outpatients. Average isolation number was 4 strains/month of the bacteria in the previous months. Nine of 67 strains were belong to true infection. Thirty-five of them were isolated from cathether tips and 11 from deep tissue biopsy specimens. *S. marcescens* was also isolated from the saline solution in culturing area of the laboratory and recognised that he technician has been using the same stock saline solution for processing the specimens without changing needle. RAPD patterns of the isolates were identical with the pattern of saline strain. The contaminated saline solution was discarded, the technician was educated and no additional cases of suscepted contamination has been observed.

Conclusion: This pseudo-outbreak emphasise the importance of the periodic observation of specimen processing procedures and education of laboratory workers in the microbiology laboratory.

P799 A nosocomial outbreak of CTX-M producing *Serratia marcescens* in a Bulgarian neonatal hospital unit

R. Vatcheva-Dobrevska, I. Ivanov, E. Georgieva, T. Kantardjiev (Sofia, BG)

Objectives: The nosocomial spread of ESBL-producing *S. marcescens* remains a significant world-wide problem although in Bulgaria it have been rarely reported. The study investigates the epidemiology of a nosocomial outbreak of ESBL-producing *S. marcescens* in a neonatal intensive care unit.

Methods: A total of six infants were clinically studied. Three of them have experienced various clinical symptoms, one died with meningitis and two were clinically healthy. Six isolates *S. marcescens* were cultured from CSF (1), throat aspirate (3), nasal swabs (2). Identification, antimicrobial susceptibility and tests for ESBL production were performed by VITEK 2(BioMerieux, France) and conventional methods. PCR detection of CTX-M, SHV and TEM ESBL encoding genes was performed. Molecular typing was carried out by using ERIC-PCR and REP-PCR. The six isolates were compared with another set of 35 isolates originating from different hospitals from all over the country. The fragment analysis was carried out in a novel capillary electrophoresis instrument HDA-12 (eGene inc., USA) that generates results within eight minutes.

Results: The antibiotic susceptibility testing revealed two types. Five isolates were multidrug resistant, susceptible only to fluoroquinolones and carbapenems and one isolate was generally susceptible. Only CTX-M gene was found among the five MDR strains. The molecular typing grouped the isolates in two clusters – one containing the five identical MDR isolates and a second one including the unrelated susceptible strain. The two methods applied generated concordant results.

The general comparison with the other nosocomial isolates from the country revealed a total of five genotypes.
Conclusions: This study is the first to present molecular diversity of nosocomial *S. marcescens* isolates from Bulgaria. The applied PCR typing systems ERIC-PCR and REP-PCR proved efficient for discrimination of closely related as well as unrelated nosocomial isolates.

P800 Nosocomial outbreaks caused by *Serratia marcescens*

L. Lazarevska (Skopje, MK)

Background: Over the course of 2005, we registered and investigated two nosocomial outbreaks caused by *Serratia marcescens*. The first one occurred in the neonatal intensive care unit (NICU), at the Clinic of gynaecology and obstetrics, and the second one in the paediatric intensive care unit (ICU) of the Clinic for Children's Diseases – Medical Faculty – Skopje, R. Macedonia.
Methods: The initial and final Information were elaborated by the Department of Epidemiology and the Department of Microbiology at the PHO Institute for health protection-Skopje. During the outbreaks, throat, nose, and eye swabs, as well as blood samples were taken from every patient hospitalised in the ICUs. Materials from working surfaces and medical staff were taken for bacteriological investigation.
Results: *Case A*: In January 2005, 10 premature infants in NICU were infected (n = 5) or colonised (n = 5) by *Serratia marcescens*. Four of them developed septicaemia, which was fatal for one of the babies. One baby had conjunctivitis, and five babies had no clinical symptoms.
Case B: In July, 2005, seventeen newborn babies were registered in outbreaks caused by *Serratia marcescens* in ICU. Five babies suffered from septicaemia, in ten cases bacteria were isolated from the trachea, in one case from the nose and there was one case with eye-isolated bacteria.
Apart from *Serratia marcescens*, we registered five cases with *Klebsiella aerogenes* (n = 5) and *Pseudomonas aeruginosa* (n = 5).
Only six babies manifested clinical symptoms and all babies were treated with antibiotic regimen.
Conclusions: Throughout both nosocomial outbreaks, the units were partially closed, the infected newborn babies were isolated and a general cleaning was carried out, as well as disinfecting of all units. The supply of antibacterial soap was replenished and the babies were not breast-fed, but put on formula feeding.
A focal source for all micro-organisms was not identified, but we believe that bacteria transmitted via contaminated hands play an important role in the outbreaks. Cohorting, isolation of colonised and infected newborn babies, and rigorous environmental hygiene were crucial measures in preventing further hospital infections.

P801 Measles outbreak and serological testing of healthcare workers in a Spanish hospital

V. Pascual, S. Gonzalez, E. Calbo, M. Riera, M. Rodriguez-Carballeira, J. Garau (Terrassa, ES)

Background: In 1981 the combined measles-mumps-rubella vaccine was introduced in Catalonia. In 2006 the Public Health Department reported that the prevalence of IgG measles antibodies was ~99% in children and adult population. Recently, a measles community outbreak occurred in our area. A patient was diagnosed of measles on his 7th day of hospital stay. CDC recommendations state that healthcare workers (HCW) with direct patient contact and without documented immunity should be vaccinated as soon as possible and relieved from direct patient contact, from the 5th to 21st day after exposure. This measure is costly and represents a considerable burden for the hospital. The objective of the study was to determine the prevalence of measles antibodies among HCW and to evaluate a questionnaire as a screening tool.
Material and Methods: This was an observational study in an acute care hospital in Terrassa, Spain. All HCWs born between 1966 and 1980 were included. A questionnaire regarding previous exposure or immunisation with the triple vaccine was used. ELISA immunoassay was used to measure measles IgG antibody titres. HCW with exposure to the index case were relieved from direct patient contact until final serological results were obtained.
Results: 44 HCW were exposed. Only one seronegative HCW was relieved from patient contact for 15 days. 586 (91.7%) out of 639 HCW were tested. 6 (1%) refused serological testing, 78.4% were women. Median age was 33 years. 74% were physicians and nurses. 22.5% referred a previous measles episode, 29% previous vaccination, 4.2% referred both, and 55% did not refer any previous disease or vaccination. The seroprevalence was 90%, 81%, 80%, and 86%, respectively. In the whole cohort the prevalence of IgG antibodies was 86%. The sensibility of the questionnaire was 85.6% and the specificity was 14%.
Conclusions: Seroprevalence of measles antibodies in HCWs was high but lower than expected. Data obtained through personal interview did not provide accurate information as to be used as a surrogate for immunity. In case of a nosocomial outbreak, the determination of the immune status in exposed HCW is useful in order to avoid unnecessary interventions. All HCWs must be tested and, if necessary, vaccinated before their incorporation into the hospital.

P802 Uncommon nosocomial transmission of TBC in an outpatient clinic in 2005: possible route of pathogen

T. Eckmanns, H. Epple, H. Karcher, P. Buchholz, P. John, T. Schneider (Berlin, DE)

Objectives: We report an uncommon nosocomial transmission of *Mycobacterium tuberculosis* in an outpatient ear, nose and throat (ENT) clinic. The first patient suffered from an acute otitis media. The second patient complained about sudden deafness. The index patient was diagnosed with tuberculosis otitis media 3 months after the initial diagnosis. The second patient was diagnosed with tuberculosis otitis media 5 months after the initial diagnosis and 3 months after the index patient.
We investigated the contact situation regarding the two patients and the probable route of transmission.
Methods: The case histories were checked for possible contact between the two patients. The similarity of the pathogens was investigated by molecular methods. The hygienic situation of the outpatient clinic was audited and the hygienic plausibility of the transmission of the pathogens was investigated by laboratory experiments. Potential other contacts in the clinic were traced back and investigated using a t-cell based assay (Elispot) for IFN-gamma.
Results: Both patients met once in the ENT clinic. Both had an invasive ear examination on this day. Microbial investigation revealed the same clonal pattern.
The audit revealed incomplete compliance with hygienic necessities, especially concerning hand disinfection and environmental disinfection between different consultations (e.g. contact to ear microscope). In addition, staff reported that the rinse water of the ear suction device was not changed between consultations. An experiment proved a possible contamination of the suction device by contaminated rinse water. A second experiment showed that the flyback of rinse water in the upside down hanging suction device was able to contaminate the apex of the device.
None of the 10 contacts, who were treated in the ENT clinic on the same day revealed a positive result in the Elispot.
Conclusion: Investigations demonstrated probable transmission in the outpatient clinic. Different routes of transmission are possible. A lecture in hand disinfection was given and a new hygienic management was established which included systematic disinfection of patient environment between consultations. In addition structural changes like a hanger for the suction device were established. Hygienic management is a challenge in ENT clinics, as patient turnover is high, infectious disease are common and many medical devices are used.

P803 Audit of pulmonary tuberculosis management in a hospital with high tuberculosis prevalence: a tool for quality improvement in tuberculosis control

M. Hites, C. Melot, S. Van Den Wijngaert, A. Dediste, S. De Wit, M. Gerard (Brussels, BE)

Objectives: To avoid nosocomial TB transmission, infection-control measures, using administrative controls, engineering controls and personal respiratory protection are recommended by the CDC. An audit on the implementation of these administrative controls was performed at Centre Hospitalier Universitaire Saint Pierre (CHUSP), a public hospital in Brussels, Belgium, with high incidence of TB admissions. In countries with low TB incidence like Belgium, many doctors lack experience in recognition of RTB.

Methods: A retrospective observational study on all patients admitted to CHUSP, with suspicion of active respiratory TB (RTB) or with positive cultures for *M. tuberculosis* from a respiratory specimen, between January 1, 2002 and December 31, 2006. The use of airborne precautions (AP) was evaluated for each hospitalisation episode (HE). A decision tree for predicting active RTB based on 4 criteria (upper lung infiltrate at the chest X-Ray, fever, weight loss and CD4 count), elaborated by El-Solh and al. (Am J Respir Crit Care Med 1997; 155: 1711–16), was tested. Median TB management intervals (25th and 75th inter-quartiles) were calculated. Intervals exceeding 24 hours were considered to be a delay.

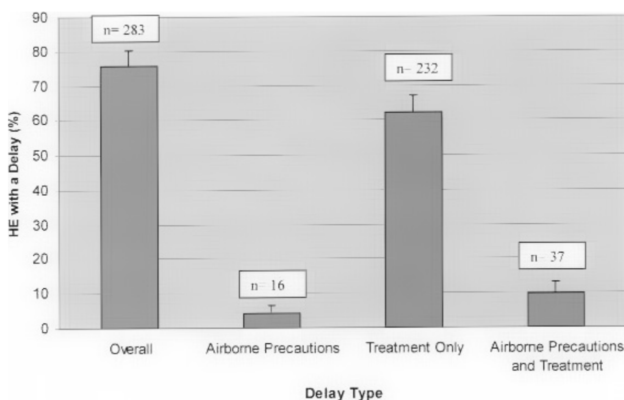


Figure: % of HE with delays in diagnosis and treatment in active RTB (n = 374).

Results: The incidence of active RTB from 2002 to 2006 was 4.25/1000 admissions. The cohort consisted of 971 HE. The ratio of active RTB to number of AP HE was 374/962. Among the 374 HE with active RTB, there were 92 AP failures (51 delays in TB suspicion, and 41 AP stopped prematurely). Theoretical delays in TB suspicion (10/364: 2.75%) generated with the decision tree were significantly inferior to the observed delays (46/364: 12.64%, p: 0.008). The median TB suspicion, treatment and overall management interval was: 0 (0–6) days, 3 (1–6) days and 4 days (1–7 days), respectively [figure: % of patients with delays in diagnosis and treatment in confirmed RTB (n = 374)].

Conclusions: APs are not correctly implemented in 25% of patients diagnosed with active RTB at CHUSP. Although overall TB management intervals seem reasonable, they are under-estimated, as some patients with active RTB are referred to CHUSP by other institutions. Results will be presented by distinguishing HE referred from other institutions to those HE entirely managed by CHUSP medical fellows. The retrospective utilisation of a decision tree has increased sensibility of RTB detection from 84% to 97%. Prospective evaluation of the tree is required to test specificity.

P804 The influence of patient heterogeneities on healthcare-associated infection, epidemic behaviour and control

J.V. Robotham, D.R. Jenkins, G.F. Medley (London, Leicester, Coventry, UK)

Objectives: Mathematical models have shown patient movement patterns to be important to healthcare-associated infection (HCAI) epidemic behaviour. Increased understanding of patient and hospital heterogeneities influencing these patterns would be of potential benefit for infection control. The objectives of this work are to: i) characterise the patient population and describe their movements within a healthcare network; ii) determine the consequences of these movements for HCAI epidemic behaviour and control.

Methods: We analysed seven years of admission data from a UK NHS Trust enabling us to fully characterise the demographics and network of movements between the three hospitals comprising the Trust. Consequences of these patterns for infection transmission and control were explored using mathematical models of infection spread, using both analytical and simulation-based methods.

Results: Despite most patients only visiting hospital a few times (40% being seen only once), for the final three years of data, readmitted patients constituted nearly 80% of admissions (numbers were lower in the first four years, attributable in part to left censoring), with approximately 80% of these being within one year.

Readmissions varied between demographic groups; most notably young women (21–30 yrs) and the elderly appeared to be ’core groups’ (the latter being a greater threat for HCAI). Analytical results showed effective isolation of these patients on admission (or clearing carriage at discharge) approximately halved their transmission potential.

Simulation results showed hospitals with the greatest number of admissions and whose patients were most likely to be readmitted had higher prevalences. Movement patterns were found to be critical to control success. For example: in a setting where each patient has, on average, 1.5 infectious admissions, admission screening has little benefit; whereas for an average of 2 infectious admissions, a strategy allocating 60% of its resources to screening the admission population is optimal.

Conclusions: Readmissions constitute a substantial proportion of the admission population and their consideration is likely to be crucial to the design of effective and cost-effective control strategies. Heterogeneities in movement patterns between hospitals imply optimal control strategies may vary between institutions. Future work will focus on investigation of tailored control strategies that identify and target patients at high risk of readmission.

P805 Scabies outbreak in an acute care setting involving 1,075 individuals

M. Buehlmann, H. Beltraminelli, C. Strub, X. Jordan, P. Itin, A. Widmer (Basel, CH)

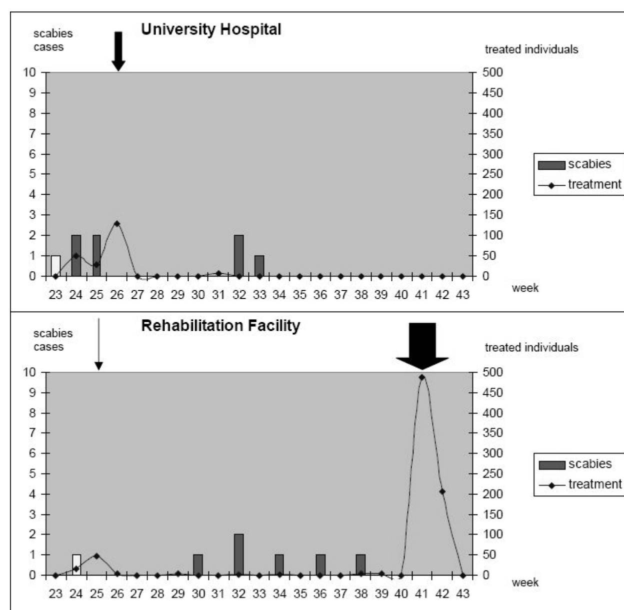
Objectives: Sarcoptes scabiei is an ectoparasite that causes either sporadical or in institutional outbreaks. We report a large outbreak in an University Hospital and a Rehabilitation Facility, that was controlled only after several months by strict infection control measures (IC).

Methods: *Setting:* University Hospital: primary and tertiary care centre with 750 beds, 39 intensive care unit (ICU) beds and 27,000 admissions per year. Rehabilitation Facility: primary and tertiary care centre with 92 beds (8 ICU beds) for patients with complex disabilities, spinal cord and brain injuries.

Epidemiological investigation: Scabies case definition: 1) positive skin scrape or 2) dermatoscopy or 3) typical burrows without history of prior scabicide treatment. Attack rate: The attack rate was defined as the number of symptomatic healthcare workers (HCW) in relation to all HCW exposed to scabies, and was evaluated by a standardised questionnaire.

Interventions: Individuals with scabies: treatment, contact precautions until 24 hours after initiation of treatment. HCW in contact with index case: preemptive treatment, including all household members (HM).

Patients in contact with the index case or infected HCW: dermatological examination, later preemptive treatment for all patients.
Results: In June 2007, a HIV patient was diagnosed with Norwegian scabies (crusted scabies) after a 6 week hospitalisation in the ICU of an University Hospital and consecutive transfer to a Rehabilitation Facility.
University Hospital: 4 HCW and 3 HM and no patients were diagnosed with scabies within 9 weeks from June to August 2007. The attack rate was 18% in HCW overall, 27% for HCW with direct contact to the index case and 10% for HM. The outbreak was finished in August after initiation of strict IC.
Rehabilitation Facility: No diagnosis of scabies was made at the beginning of the outbreak. Two HCW, 2 HM and 2 patients were diagnosed with scabies from July to September 2007 due to difficult implementation of IC. The attack rate of HCW was 3.9%, and 12.9% for HCW with direct contact to the index case. The outbreak stopped after simultaneous preemptive treatment of all HCW and patients in the Rehabilitation Facility.
Overall, 1075 individuals underwent preemptive treatment.
Conclusions: Case finding during scabies outbreaks is impaired by uncertain diagnostic tests in the early stage of disease. Therefore, in a hospital setting, early broad preemptive treatment and strict IC are essential for control.



Healthcare-associated infections

P806 Prevalence of nosocomial infections in Lithuania

R. Valinteliene, V. Jurkuvenas (Vilnius, LT)

Objectives: The main objective of the surveys was to determine prevalence of nosocomial infections and risk factors in Lithuania.
Methods: Nation-wide point prevalence surveys of nosocomial infection (NI) were undertaken in 2003, 2005 and 2007 in 39, 35 and 30 acute hospitals correspondingly. Data were collected during bedside interviews by the medical doctors recording current status of patient. CDC criteria were used for NI diagnosis.
Results: There were app 8000 patients evaluated each year. The prevalence of nosocomial infections revealed was in 2003 – 4.3%, 2005 – 3.4%, 2007 – 3.5%. Prevalence of hospital acquired infections varied widely between departments wit top level in intensive care (app. 20%). It was clear tendency of increasing NI prevalence in nursing departments, where NI prevalence in 2007 (6.3%) exceeded surgical (4.6%) and trauma (5.5%) departments. The most prevalent NI were those of respiratory tract, accounting (accounting up to 30.1–44.3% of all NI) and surgical site infections (14.7–22.6%). Prevalence of risk factors was significantly higher in university hospitals compared to regional and local in all three surweys, but there was no difference in nosocomial infection prevalence rates.
Conclusion: Prevalence studies give the realistic view on NI problem, allows to follow national NI tendencies and gives valuable data needed for NI control.

P807 Increasing numbers of *Rhodococcus* infections at a large university hospital NHS Trust, Nottingham – An investigation

S. Capewell, J. Palfreyman (Nottingham, UK)

Objectives: Towards the end of October 2003 an unusual organism was grown from a number of paediatric blood culture bottles from one of the children on the Oncology Ward at the Nottingham City Hospital Campus. Routine Laboratory identification Tests as to the identification and significance of this Gram-positive organism were inconclusive. The Reference laboratory subsequently identified the organism as *Rhodococcus* sp. (not *Rh. equi*). The isolation of this type of organism increased over the following months and it was decided that an epidemiological investigation was required to find the source of infection and to prevent further outbreaks in a ward of vulnerable children.
Methods: A number of epidemiological methods were engaged to assess the outbreak. These included a study as to where the patient came from, a case assessment including time from line to infection, line usage, age and sex, as well as what type of underlying disease. A review as undertaken to see if this increase in infections caused by *Rhodococcus* sp. was occurring elsewhere in the hospital or the United Kingdom. Finally screening and environmental swabs were taken as well as a generally survey of the ward.
Results: There were no conclusions or similarities to be drawn from the case reviews or screening swabs. This increase in *Rhodococcus* infections had not been noticed in any other areas of the hospital or elsewhere within the region or country. On investigation of the Ward it was found that the HEPA filters had never been changed. These were removed and swabbed. *Rhodococcus* sp. was grown from 3 areas of the filters. Since their removal no more cases have been seen at Nottingham University Hospitals.
Conclusions: This was a nosocomial infection. The HEPA filters were the source of the *Rhodococcus* sp. infections seen in the Oncology ward at Nottingham University Hospital.

P808 Clinical and autopsy diagnosis of infectious diseases at an Italian teaching hospital

M. Bonadio, G. Andreotti, G. Pieroni, M. Castagna (Pisa, IT)

Objectives: To evaluate the frequency of autopsy diagnosis of infectious diseases and to compare clinical and autopsy findings of infectious diseases at an Italian teaching hospital
Methods: A comparison of clinical and autopsy findings of cases studied between january 2001 and march 2007 at the Department of Pathology of Pisa hospital was made. A total number of 512 autopsies were performed in adult patients; 318 patients males and 194 females; mean age 65.0 yrs ±15.4 SD. 160 patients died in medical wards, 115 in intensive care units, 88 in surgical wards and 149 in emergency department. Particularly 201 cases with clinical diagnosis and/or autopsy diagnosis of infectious conditions were evaluated.
Results: 15 (7.5%) out of 201 autopsies showed no evident findings of infectious conditions while in the clinical diagnosis an infectious disease was included. 186 (36.3%) autopsies (114 males, 72 females) out of 512, revealed findings of infectious conditions involving 1 or more site of infection. Mean age of patients with autopsy findings of infectious disease was 63.3 yrs ±14.5 SD. In 72 (38.7%) out of 186 cases with autopsy findings of infections, no infectious diseases were diagnosed pre mortem. Underdiagnosis was most common in lung infections.
In 31 cases a clinical diagnosis of sepsis or septic shock was made. In 23 of these one or more sites of infection were evidentiated at autopsy. Infectious findings at autopsy included: pneumonia (n = 120), abdominal

infections (n = 27), meningitis or encephalitis (n = 8), pulmonar and/or extrapulmonary tubercolosis infections (n = 11), endocarditis (n = 15), invasive fungal infections (n = 12), AIDS/HIV (n = 3), HCV severe chronic hepatitis or cirrosis (n = 14), viral systemic infections caused by Herpesviridae (n = 8), urinary tract infections such as kidney abscess and acute pyelonephritis (n = 8).

Conclusions: These data underline the relative high frequency of infectious diseases at autopsy. The number of cases with clinically missed infectious conditions at autopsy was particularly high in lung infection and endocarditis. This fact confirms the difficulty in reaching a correct and timely diagnosis for this kind of infections in critical ill patients.

P809 Estimating disease burden of healthcare-associated infections in Finnish acute care hospitals

M. Kanerva, J. Ollgren, O. Lyytikäinen (Helsinki, FI)

Objectives: Few population-based estimates of disease burden for healthcare-associated infections (HAI) exist. We estimated the morbidity and mortality related to HAIs based on the data from the national prevalence survey performed in 2005. We also evaluated the completeness of the National Hospital Discharge Registry (HILMO) as a source of HAIs.

Methods: Data from the national prevalence survey constituted the basis for the register linkage. The survey included all inpatients (n = 3234) in acute care wards for adults in 30 hospitals. The Center for Disease Control and Prevention (CDC) definitions for HAIs were used and McCabe classification for comorbidity. In total, 753 HAIs were recorded in 703 patients (prevalence of HAI patients, 8.5%). Using the date of the prevalence survey and the patient's national identity code, data on hospitalisations including International Classification of Diseases (ICD)-10 codes for discharge diagnoses were obtained from HILMO, and the dates and causes of death from the National Population Information System. The incidence of HAI was calculated by Rhame and Sudderth formula using the prevalence (%), mean length of hospitalisations and mean number of days before HAI onset. Using the incidence of HAI and the 28-day case fatality of HAI patients in the prevalence survey, the annual estimates were extrapolated from the total number of hospitalisations in adult specialties in all Finnish acute care hospitals in 2005 (n = 304,456).

Results: In Finland (population, 5.2 million), we estimated that annually a total of 48,267 hospitalisations in adult acute care wards ended up to at least one HAI (9282 HAIs per million population) and 1514 patients with HAI died within 28 days (291 deaths per million population); 62% of the HAI patients who died did not have an ultimately fatal underlying disease (181 deaths per million population). In 33% of the hospitalisations with HAI, ICD-10 codes in HILMO indicated an infection. The proportions of HAIs coded in HILMO varied according to the severity of HAI: from 53% of surgical site/organ space infections, and 45% of pneumonias to 6% in urinary tract infections.

Conclusions: Our disease burden estimates can be used in healthcare planning and resource allocation. Notably, they did not cover paediatrics. The sensitivity of discharge diagnoses to recognise HAIs was low, but should not be overlooked as an additional case finding method, especially for severe HAIs.

P810 National 14-year survey of nosocomial meningitis in children and comparison of two periods, 1993–1998 to 1999–2006

B. Rudinsky, A. Ondrusova, P. Kisac, P. Beno, J. Miklosko, P. Fedor-Freybergh, F. Bauer, M. Huttova, M. Sramka (Nove Zamky, Bratislava, SK)

Introduction: In 1993–1998 and in 1999–2006 we have performed 2 surveys of paediatric bacterial meningitis in all 8 neurosurgery/paediatrics and infectious diseases departments in Slovakia.

Patients and Methods: In a prospective multicentric observational study, a prospective protocol was used to assess every case of meningitis appearing in clinically hospital stay in 0–18 years old patients in all 8 paediatric neonatal or neurosurgery departments in Slovakia. At least one positive CSF culture was involvement criteria. Mortality on infection, and/or CNS sequel and treatment (surgery, antibiotics) were analysed.

Results: 171 cases were enrolled. Comparing the two periods in our study of nosocomial meningitis 1994–1998 (A) to 1999–2004 (B) in aetiology, Gram-negative aetiology was more frequent in the second period (B) 40% vs. 2 5.3%, $p<0.05$). Vice versa fungi were more frequently obtained in the first period (8.7% vs. 2.0%, $p<0.05$). All *S. aureus* were oxacillin (OXA) resistant

Concerning Gram-negative bacteria *Acinetobacter baumannii* (14 vs. 6.1%) and *Pseudomonas aeruginosa* showed emergence (8 vs. 5.2%). Six (6) of 18 (30%) Enterobacteriaceae were cefepim resistant. Three *Ps. aeruginosa* isolates of 9 were resistant to meropenem.

Analysing mortality, there was no significant change in mortality among two periods of time (14.0% and 14.1%, NS), however there was a significant decrease of neurologic complications (e.g. hydrocephalus, palsy, epilepsy), in the 1999–2004 (29.9%) in comparison to 1993–1998, (42.9%, $p<0.01$). In contrast to that, cerebral abscess as a complication of meningitis appeared more frequently in 1994–2004 (14.3% vs. 3%, $p<0.02$).

Conclusion: There were no major changes in aetiology of nosocomial meningitis in children comparing 1993–1998 and 1999–2006, despite there was a trend towards in the increase of *Ps. aeruginosa* and *Acinetobacter baumannii* (9–12%), but the trend was only marginally significant for Gram-negative bacteria (35.5% vs 2 5.3%). Alarming was the level of resistance to teicoplanin in coagulase negative staphylococci – more than 10%. Mortality remains unchanged (12% in 1999–2006 in comparison to 15% in 1993–1998), but the number of neurologic sequellae decreased, probably because the proportion of inappropriate treated cases decreased from 20% to 10.3%. Nosocomial postoperative meningitis is still not a rare disease with 10–15% mortality and should be effectively prevented, and if occurs, radically treated with ATB.

P811 Risk factors and prognosis of external ventricular drainage-related infection

E. García-Cabrera, E. Jimenez-Mejías, J. Serra-Vich, J. García de Chuz, M. Portillo, V. Pintado, J. Colomina, G. Prats, J. Pachón-Diaz on behalf of the Spanish Network for the Research in Infectious Disease (REIPI)

Objective: To study the risk factors associated to external ventricular drainage (EVD) related infection.

Methods: Cohort study carried out since May 2004 to December 2006 in six tertiary hospital of Spanish Network for the Research in Infectious Diseases (REIPI). Inclusion criteria: Adult patients ($\geqslant$14 years) with EVD, during more than 24 h. Exclusion criteria: previous infection of central nervous system (CNS) at catheter's insertion day or death in the first 24 hours. All patients were followed until catheter withdrawal, infection, or exitus. Cases with EVD-related infection (EVDRI) defined by: a) clinical features (fever, meningeal signs, low Glasgow coma scale [< 14 or lower than previous status]); b) CSF findings (pleocytosis $\geqslant$100/UL, hipoglycorrachia < 40 mg/dL or CSF/blood glucose ratio <40%, and increased protein level > 100 mg/dL); and c) microbiological criteria (positive CSF Gram-stain, positive culture of CSF and/or catheter's tip). Patients without EVDRI were compared with cases. The end-points were the EVDRI and exitus, and the independent variables were: sex, age, diagnosis at admission, underlying diseases, prophylaxis, concomitant infections, previous antibiotic treatment, and those related to catheter use, including the need of catheter exchange. To control the interaction/confusion between variables a model of binary logistic regression adjusted by Wald test was used; significant differences were defined as $p< 0.05$.

Results: 323 patients were included, the median of catheterisation time was 10 days (2–88) days. The infection rate was 11.4% (37 patients). Thirty-four (91.8%) were monomicrobial; aetiological agents: Gram-positive cocci 17 (32.5%), Gram-negative rods 20 (50%), others 3 (7.5%). Independent risk factors associated to EVDRI were: age (OR 0.958, CI 95% 0.93–0.98); underlying disease (OR 2.80, CI 95% 1.11–7.07); Apache II (OR 1.12, CI 95% 1.04–1.22); catheter exchange (OR

9.58, CI 95% 3.14–29.20), prophylaxis at first catheter (OR 0.20, CI 95% 0.07–0.66). The mortality rate was 24.3% in EVDRI group and 21% non-infected patients (p = NS).
Conclusions: EVDRI is affected by the need of catheter exchange, the initial severity of patients, and comorbidity. Prophylaxis before the insertion reduced the EVDRI. EVDRI is not associated to higher mortality.

P812 Clinical significance of nosocomial spontaneous bacterial peritonitis in liver cirrhosis patients and impact of the 3rd generation cephalosporin resistance of Gram-negative bacilli on the outcome

H.S. Cheong, Y.M. Wi, E.S. Kim, C.I. Kang, D.R. Chung, K.R. Peck, N.Y. Lee, J-H. Song (Seoul, KR)

Background: There have been few reports of the aetiologies and treatment outcome for nosocomial spontaneous bacterial peritonitis (SBP) in liver cirrhosis (LC) patients.
Objectives and Methods: We performed a retrospective cohort study to compare the microbiological and clinical characteristics and outcome between nosocomial and community-acquired SBP in LC patients. All cases of SBP, in which culture was proven at Samsung Medical Center from Jan. 2000 to Jun. 2007 were included. Medical records and laboratory data were reviewed. Nosocomial SBP was defined as SBP diagnosed after 72 hours of hospitalisation.
Results: A total of 236 patients with SBP were enrolled (mean age, 56.6±10.7 years; male/female, 166/70). Nosocomial and community-acquired SBP were 126 and 110 cases, respectively. Among 239 microorganisms isolated, *Escherichia coli* accounted for 43.2%, *Klebsiella* spp. 14%, *Streptococcus* spp. 9.7%, *Enterococcus* spp. 8.1% and *Staphylococcus aureus* 5.1%. The overall mortality rate of nosocomial SBP was higher than that of community-acquired SBP (58.7% vs. 37.3%, p = 0.001). Nosocomial isolates of Gram-negative bacilli (GNB) were significantly more resistant to 3rd generation cephalosporin (42.1% vs. 10.0%, p < 0.001) and quinolone (30.9% vs. 50.0%, p = 0.003) than community isolates. Multivariate analysis revealed that nosocomial infection, concomitant hepatocellular carcinoma, presentation with shock, elevated creatinine and resistance to 3rd generation cephalosporin of GNB were significant risk factors for the 30-day mortality in SBP.
Conclusions: Nosocomial SBP has a poorer outcome than community-acquired SBP. The resistance to the 3rd generation cephalosporin of GNB, which is more frequent in nosocomial SBP than in community-acquired SBP, adversely affects the outcome of SBP in LC patients.

P813 Significance of positive urine cultures during the immediate post-trasnplant period in renal transplant recipients. A retrospective study

M. Koukoulaki, I. Baraboutis, E. Platsouka, V. Papastamopoulos, V. Hadjiconstantinou, O. Paniara, A. Skoutelis, S. Drakopoulos (Athens, GR)

Purpose: Urinary tract infections (UTI) are the commonest bacterial infections in renal transplant recipients. The study of UTIs in the immediate post-transplant period is of particular importance (higher degree of immunosuppression, presence of foreign bodies, exposure to nosocomial pathogens). Purpose of this retrospective study was to audit UTIs during the first post-transplant month and identify potential risk factors.
Patients and Methods: Renal transplant recipients with complete urine culture (UC) and urinalysis data for the first post-transplant month (period of September 2002-September 2007) were included in the study. All recipients, besides the induction therapy and triple immunosuppressive regimen, were treated with prophylactic antibiotics, namely intravenous cephotaxime for 10 days and then per os ciprofloxacin for six weeks.
Results: 116 renal transplant recipients (mean age 50.6±9.7 years, male gender in 74.1%) were studied. During the follow-up period of one month, 50 positive UCs were identified, derived from 38 (32.7%) recipients. A total of 27 recipients had only one positive UC. Urinalysis identified pyuria in 18 out of 38 recipients. Most frequent pathogens were Gram(+) bacteria (22/50.44%) (*Enterococcus faecalis* commonest), followed by Gram(–) bacteria (17/50.36%) (*Pseudomonas aeruginosa* commonest) and fungi (11/50, 22%) (3 *Candida albicans*, 8 *Candida* non-*albicans*). Mean time of identification of positive UC was 14±4.7 days post transplantation. Preliminary statistical analysis revealed significant association of probability of a positive UC with female gender (Pearson χ^2, p = 0.043) and cold ischaemia time (non-parametric test Mann Whitney U, p = 0.005). When the analysis included only the positive UCs accompanied with significant pyuria (defined as ⩾8–10 white cells/hpf), the above-mentioned associations were not reproduced.
Conclusions: Positive UCs were observed in 32.7% of renal transplant recipients, with *Enterococcus faecalis* and *Pseudomonas aeruginosa* being the commonest pathogens. It should be emphasised that all patients with positive UCs received specific antimicrobial therapy, irrespective of symptoms or puyria, due to concerns for defective inflammatory response. The issue of when to treat an isolated positive UC by a potential pathogen in the immediate post-transplant period has not been resolved. The probability of a positive UC in the first post-transplant month was related to female gender and cold ischaemia time.

P814 First results of ventilator-associated pneumonia results in five Dutch hospitals

T.I.I. van der Kooi, B.H.B. van Benthem, J.C. Wille, J. Manniën (Bilthoven, Utrecht, NL)

Objectives: Since 2005 Dutch hospitals can participate in the PREZIES surveillance of ventilator-associated pneumonia (VAP), in which the incidence of VAP as well of that of several risk factors are registered. These data are analysed to assess the most important risk factors in order to feedback case mix-adjusted data to the hospitals.
Methods: Data are collected and infections diagnosed based on the PREZIES-protocol, which is based on the CDC-definitions. Surveillance ended when a VAP was diagnosed or after a maximum of 28 ventilation days per period. Data were analysed with Cox regression.
Results: Five hospitals collected data on 457 ventilation periods (3098 ventilation days) with 411 patients. The average VAP incidence was 6.3% per ventilation period (9.4/1000 ventilation days). In univariate analysis neurosurgery compared to general surgery (HR 4.1), position in bed (supine compared to semirecumbent, HR 0.3) and SDD (HR 0.18) were significantly associated with the risk of VAP. Infection frequencies differed significantly per hospital. Therefore in multivariate analysis these data were adjusted for hospital and also for non significant risk factors with a p-value < 0.2 (age group).
In multivariate analysis the VAP risk was significantly higher for patients with a mean daily sedation score of four or higher (HR 6.4, 95% CI 2.6–15.7) and for patients on oropharyngeal prophylaxis (HR 16.7, CI 2.3–118). The risk for patients who were treated with multiple dose inhalers was lower, compared to those patients not treated with inspiratory medication (HR 0.36, 0.15–0.91). The interpretation of the results is hampered by the frequent presence of collinearity.
Most frequent organisms were *Klebsiella pneumoniae* (24%), *Pseudomonas aeruginosa* (13%), *Haemophilus influenzae* (11%) and *Staphylococcus aureus* (11%). In 9 of 29 cases two micro-organisms were cultured.
Conclusion: Oropharyngeal prophylaxis, the use of multiple dose inhalers and the average daily sedation score were significantly associated with the VAP incidence.

P815 Frequency and predictors of ventilator-associated pneumonia recurrence: a meta-analysis

I. Siempos, Z. Athanassa, M. Falagas (Athens, GR)

Objective: Large clinical series focusing on the risk factors associated with recurrence after the onset of an initial episode of ventilator-

associated pneumonia (VAP) produced inconsistent results. A meta-analysis would be helpful to shed light on the issue. To estimate the frequency of VAP recurrence and to identify risk factors associated with it.

Methods: PubMed, Scopus, Current Contents and references of retrieved articles were searched, without language restrictions. Pooled odds ratios (OR) and 95% confidence intervals (CI) were calculated by using both the Mantel–Haenszel fixed-effect and the DerSimonian-Laird random effects models.

Results: The overall frequency of VAP recurrence in 1,166 patients of the nine eligible reports was 23.7%. Among the twenty evaluated risk factors, only inappropriate empirical treatment (OR=1.99; 95% CI 1.06 – 3.72), acute lung injury/acute respiratory distress syndrome (OR=1.76; 95% CI 1.12–2.75) and shock (OR=1.55; 95% CI 1.01–2.41) at the day of diagnosis of the first VAP episode were found to be associated with VAP recurrence. There was also evidence, albeit inconsistent, that severity of illness at ICU admission was associated with VAP recurrence.

Conclusion: Recurrence involves almost one in four cases of VAP and is associated with inappropriate empirical treatment, acute lung injury/acute respiratory distress syndrome and shock, but not with first-episode causative pathogens. Recognition of these predictors may permit the timely implementation of measures to prevent recurrence of VAP.

P816 Closed tracheal suction systems for prevention of ventilator-associated pneumonia

I. Siempos, K. Vardakas, M. Falagas (Athens, GR)

Objective: By meta-analysis of randomised controlled trials (RCTs), we assessed the evidence that closed tracheal suction systems (TSS) prevent ventilator-associated pneumonia (VAP).

Methods: We searched PubMed and Cochrane databases to identify RCTs that compared closed with open TSS for the management of mechanically ventilated (MV) patients.

Results: Nine RCTs were included in the meta-analysis. There was no difference on VAP incidence between patients managed with closed and open TSS [odds ratio (OR) = 0.96, 95% confidence intervals (CI) 0.72–1.28]. There was no heterogeneity among the eligible trials (I2= 0, 95% CI 0–0.65). The compared groups did not differ on mortality (OR= 1.04, 95% CI 0.78–1.39) and on intensive care unit (ICU) length of stay (one RCT: 12.3 ± 1.1 vs 11.5 ± 1.4 days, and the other RCT: 15.6 ± 13.4 vs 19.9 ± 16.7 days). Suctioning with closed systems was associated with longer MV duration (weighted mean differences: 0.65 days, 95% CI, 0.28–1.03) and higher colonisation of the respiratory tract (OR= 2.88, 95% CI 1.50–5.52) than open TSS.

Discussion: The available evidence suggests that closed as opposed to open TSS usage did not provide any benefit on VAP incidence, mortality, or ICU stay of MV patients.

P817 Opinions of intensivists and nurses towards use of selective decontamination of the digestive tract and selective oropharyngeal decontamination

I.P. Jongerden, A.M.G.A. de Smet, J.A.J.W. Kluytmans, M.J.M. Bonten (Utrecht, Breda, NL)

In the past decades, use of Selective Decontamination of the Digestive tract (SDD) and Selective Oropharyngeal Decontamination (SOD) has been object of discussion. From May 2004 to July 2006, a large group-randomised, controlled cross-over multi-centre study (13 hospitals) was performed in the Netherlands, in which the effects of SDD and SOD as compared to standard care, were determined on patient survival and antibiotic resistance. As part of this trial, assumptions by intensivists and nurses on effect of SDD and SOD, as compared to standard care, were studied, and the influence of these assumptions on compliance to the study protocol was determined.

Questionnaires were developed, based upon semi-structured interviews, to inventarise experiences of intensivists and nurses with SDD and SOD, and to inventarise assumed effect. Furthermore physicians were asked to appraise current and expected (after application of SDD) mortality rate in the included patient group. In the last week of each six month study phase, during 24 hours, all nurses and physicians received the questionnaire, which could be filled in anonymously.

Divided over three studyperiods, 1024 questionnaires were returned by nurses and 253 by physicians. Expectations on effect of SDD increased as the study proceeded, both in nurses and physicians. Physicians expected less reduction in mortality when using SDD, as compared to SOD and standard care(significant difference). The assumed relative reduction in mortality as appraised by physicians raised as the study proceeded.

Application of SDD was considered time consuming and annoying for patients, but increasingly effective.

P818 Risk factor analysis of deep sternal wound infections after cardiac surgery

K. Graf, D. Sohr, A. Haverich, A. Kola, P. Gastmeier, I.F. Chaberny (Hannover, Berlin, DE)

Objective: Deep sternal wound infections (DSWI) represent a severe problem in cardiac surgery. We observed an increasing incidence of DSWI in our university hospital in the period from January 2006 to September 2007. Therefore a case control study was performed to identify significant risk factors.

Methods: All cases of DSWI were recorded using CDC definitions over a 21 months period. All patients directly operated following a case patient were considered as control patients as long as they did not develop a surgical site infection. The following risk factors were recorded for each case and control patient: diabetes mellitus, BMI >25, COLD, renal insufficiency, nicotine abuse, immune suppression, preoperative exposure time, ASA-score, risk class stratification; date and duration of operation, time at extra corporal circulation, antibiotic prophylaxis, preoperative, intraoperative and postoperative serum blood glucose level, duration of mechanical ventilation, length of stay on ICU and in hospital. Univariate and multivariate analyses were performed.

Results: During the study period a total of 120 adult patients (72=male, 48= female) who underwent coronary artery bypass grafting (n= 91) or other cardiac surgery (n = 39) developed DSWI. On average the DSWI symptoms revealed 25 days after operation. Isolates cultured most often showed *S. epidermidis* (25%), followed by MRSA (19%), enterococci (14%), *S. aureus* (12%), coagulase-negative staphylococci (10%) and others (20%). The multivariable logistic regression model identified age greater than the median age of 68 years (OR 2.19; CI95 1.20–4.06), diabetes mellitus (OR 5.36; CI95 1.35–5.36), nicotine abuse or immune suppression (OR 5.46; CI95 1.91–17.58) and intraoperative blood glucose > 8 mg/dl (OR 2.27; CI95 1.17–4.42) as significant risk factors for DSWI. Preoperative antibiotic prophylaxis (OR 0.31; CI95 0.13–0.70) and extubation on the day of operation (OR 0.25; CI95 0.11–0.55) had a protective effect.

Conclusions: Our data mainly confirm the results of previous risk factor analysis. These findings should assist clinicians in identifying patients who are at increased risk of DSWI, as well as in developing strategies to minimise modifiable risks.

P819 Impact of skin and skin structure infections on hospital length of stay, mortality and costs: a matched cohort analysis

K.S. Akhras, S. Lin, A. Quintana, H.T. Hatoum (Raritan, Chicago, US)

Introduction: Skin and skin structure infections (SSSIs) are among the most common nosocomial infections. Given the high prevalence of SSSI infections, the potential economic impact from a health system perspective is considerable. Little is published in the literature on the impact of SSSI infections using real-world data.

Objective: To estimate excess hospital length of stay (LOS), mortality and costs attributable to SSSI.

Methods: Retrospective matched cohort study using Thomson Med-STAT data from the United States from 2001 to 2005. Patients $\geqslant$18 years of age, hospitalised $\geqslant$2 days with a secondary diagnosis of SSSI were

identified using ICD-9 codes and were matched with a control cohort of non-SSSI hospitalised patients using principal diagnosis, age, gender, and admission time frame as criteria. Up to 4 matched controls were randomly selected for each eligible SSSI case. Outcomes variables were LOS, total hospitalisation charges, and mortality. Fixed effect models and conditional logistic regression were used to analyse outcomes.
Results: Among the 1,472,965 hospitalisations, 23,681 cases were identified with secondary diagnosis of SSSI and matched with 90,235 patients (control). Cellulitis/abscess was most common (66.6%) followed by surgical site infections (21.6%), osteomyelitis (8.3%) and diabetic foot infections (2.8%). Microbiologically evaluable patients accounted for 11.7% of cases. Mean and median unadjusted LOS and charges for SSSI cases were 11.4 and 8 days and $51,311 and $27,942 compared with 6.3 and 4 days and $29,883 and $16,919 for controls. Regression models on LOS and total charges to adjustment for potential confounding variables, including frequency and number of therapeutic and diagnostic procedures performed, showed that SSSI cases incurred an additional 3.81 hospital days and $14,671. Similarly, adjusted odds-ratio of mortality between cases and control was 1.31 (95% CI 1.21–1.42) indicating an increased mortality risk in hospitalised patients with SSSIs as secondary diagnoses.
Conclusion: SSSI is associated with significantly higher LOS, total charges and mortality. Given the high number of SSSI that occur annually, the burden on the health system is considerable. More effective means to prevent or to treat SSSI will most likely be cost-saving.

P820 Outcomes and costs associated with monomicrobial and polymicrobial pathogens in patients with skin and skin structure infections

K.S. Akhras, S. Lin, A. Quintana, H.T. Hatoum (Raritan, Chicago, US)

Introduction: Although skin and skin structure infections (SSSIs) are caused predominantly by Gram-positive pathogens, polymicrobial infections and multidrug-resistant (MDR) pathogens are becoming a growing concern. Little is published about outcomes associated with monomicrobial versus polymicrobial SSSI.
Objective: To compare length of hospital stay (LOS) and hospital charges associated with monomicrobial and polymicrobial infections in patients with SSSI.
Methods: This retrospective analysis used Thomson MedSTAT data from the United States from 2001 to 2005. Patients ⩾18 years of age hospitalised ⩾2 days with a primary or secondary diagnosis of SSSI were identified using ICD-9 codes. Microbiology data were used to classify patients into microbiologically evaluable (ME) and non-microbiologically evaluable (non-ME). ME patients with infections were further classified into Gram-positive, Gram-negative, monomicrobial, and polymicrobial infections. Outcomes variables were LOS, total days of IV antibiotics and total hospitalisation charges.
Results: Of the 1,472,965 hospitalisations, 44,743 cases were identified as SSSI of which 5403 (12.1%) were ME. The overall unadjusted mean and median LOS and total charges for SSSI cases were 9.4 and 6 days and $40,150 and $ 20,911. Overall mean days of IV antibiotics therapy was 8 days. The table reports results by pathogen type for ME SSSI cases.

Unadjusted LOS and total hospitalisation charges by pathogen type

	Monomicrobial*		Polymicrobial*
	Gram-positive N = 2889	Gram-negative N = 907	All polymicrobial N = 1607
LOS, mean (median)	9.3 (6)	9.9 (7)	14.9 (8)
Antibiotics therapy days, mean	8.2	8.3	11.0
Total charges, mean (median)*	$37,684 ($19,053)	$42,001 ($20,771)	$68,538 ($26,789)

*Not all patients had charge data available.

Conclusion: In this large database, SSSI type infections caused by polymicrobial pathogens were associated with longer LOS, longer treatment duration with IV antibiotics, and higher total charges compared with monomicrobial infections.

P821 The epidemiology of hospitalised cases of skin and soft tissue infection in Europe

S. Pulgar, M. Mehra, A. Quintana, A. Kempel (Raritan, US; Freiburg, DE)

Objectives: Data on complicated skin and soft tissue (SSTI) infections are scarce and a comprehensive assessment of all segments of SSTIs is not available. Therefore, the purpose of this study was to provide a thorough overview and in-depth insight to the burden of SSTI (distinguishing between community- and nosocomially-acquired infections) in European countries based on a detailed analysis of available statistical data, surveys and publications.
Methods: A multi-step approach using country-specific hospital discharge and surveillance data and data derived from a literature review were chosen to analyse the burden of SSTI in France, Germany, Italy, Spain and the UK. Relevant publications were identified through MEDLINE search of the medical literature (2000–2007) using the terms abscess, cellulitis, wound infection, ulcer wounds, skin and soft tissue infections. Annual hospitalisations for infections (cellulitis, abscesses, cysts) and underlying diseases susceptible to SSTI (burns, diabetic complications, decubitus ulcers, trauma) were extracted from annual country-specific hospital discharge surveys. Incidence rates for surgical site infections were obtained from the 2005 Hospital in Europe Link for Infection Control through Surveillance (HELICS).
Results: The analysis resulted in an estimated number of 1.3 million hospitalised SSTIs in 2004 in the EU-5. Of these, more than 25% were nosocomially acquired skin infections, while the majority of SSTIs were community-acquired or acquired in long-term care facilities. The largest proportion of all hospitalised SSTIs were cellulitis amounting to 52.7% of all SSTI, followed by surgical site infections with 15.8%, diabetic skin infections amounting to 15.3%, decubitus ulcer infections to 12%, traumatic wound infections (burns, fractures, other open wounds) to 4.2%.
Conclusion: These findings highlight the burden of SSTIs and associated underlying conditions in Europe. The summarised overview on all segments of SSTIs provides a better understanding of the large number of SSTIs and their origin.

P822 Post-operative bacterial meningitis: a 2-year study in a neurosurgery department

E. Samaras, M. Varvarou, E. Vartzioti, K. Bakopoulos, G. Bethimoutis, I. Stergiou, V. Varsos (Athens, GR)

Introduction: Post-operative bacterial meningitis is defined by a positive CSF culture in patients with clinical and laboratory findings indicative of meningitis and is associated with a wide variety of conditions requiring neurosurgical management.
Material and Methods: 745 patients who were operated on due to craniocerebral injury (CCI) or non-traumatic pathology (Non CCI) in the Neurosurgery Department of "Red Cross" Hospital, Athens, in the period 2005–2006. Meningitis, was diagnosed in 18 patients (14 male, 4 female), mean age 49.06 years. The records of patients were Statistical analysed by the statistical package SPSS 13 for Windows.
Results: Post-operative bacterial meningitis was observed in 2.4% (18) of the patients. The incidence rates meningitis among patients with CCI and those without CCI were 4.31% and 2.07%, respectively. Among patients with CCI, mortality reached 20%, while death was the final outcome of post-operative meningitis in 30.77% of the patients with non-traumatic pathology.
The mean age of patients who recovered fully was 46 years and that of patients who eventually died was 56 years..Age forms an independent prognostic factor for the outcome of postoperative meningitis ($p<0.05$).
In decreasing order of frequency, the isolated pathogens were as follows: *Acinetobacter baumannii*, *Staphylococcus* spp., *Enterococcus*

spp., *Enterobacter* spp., *Pseudomonas aeruginosa*, *Alcaligenes faecalis*, *Corynebacterium*. Eleven patients developed meningitis during their stay in ICU. Of these, 5 eventually died (45.45%). Mortality among patients stay in the Neurosurgery department was zero. Patients stay in ICU as a result to bad clinical-physical status they presented the worst outcome to post operative meningitis ($p<0.05$).
Conclusions: (1) Age was shown to be a statistically significant determinant of survival among those who developed post-operative meningitis ($p<0.05$). (2) The final outcome is worse in patients staying longer in ICU ($p<0.05$), compared to patients managed in the neurosurgery department. (3) The post-operative day that a CSF culture becames positive was not related to the final outcome of the CNS infection. (4) The incidence of resistant microbes mainly Gram(–) is increased.

P823 Treatment of joint prosthesis infection according to current recommendations improves outcome

B.Y. Betsch, S. Eggli, K.A. Siebenrock, M.G. Täuber, K. Mühlemann (Berne, CH)

Objective: Evaluation of recently recommended treatment modalities for prosthetic joint infection (PJI).
Methods: A retrospective cohort analysis of 68 patients with PJI of hip or knee treated between 1995 and 2004 was conducted at the University Hospital Bern (Bern, Switzerland).
Results: A two-stage exchange was the most frequently (75%) surgical strategy, followed by retention/debridement (17.6%), one-stage exchange (5.9%), and resection arthroplasty or suppressive antimicrobial treatment (1.5%). The chosen strategy was in 88% in agreement with the recommendations. Adherence was only 17% for retention/debridement and 0% for one-stage-exchange. Most (84%) of PJI were treated with an adequate or partially adequate antimicrobial regimen. Recurrence free survival was observed in 51.5% of PJI episodes after 24 months follow-up. The risk of failure was significantly higher in PJI with a surgical strategy other than recommended (Hazard ratio (HR) 2.34, 95% confidence interval (CI) 1.10–4.70, $p=0.01$), and in PJI with antibiotic treatment not corresponding with recommendations (HR 3.45, CI 1.50–7.60, $p=0.002$). Other risk factors associated with lack of healing were a high infection score at the time of diagnosis (HR 1.29, CI 1.10–1.40, $p<0.001$) and presence of a sinus tract (HR 2.35, CI 1.10–5.0, $p=0.02$).
Conclusions: Our study demonstrates the value of current treatment recommendations. Inappropriate choice of conservative surgical strategies (such as debridement and retention) and inadequate antibiotic treatment are associated with failure.

P824 Tolerability of prolonged linezolid-rifampicin combination in bone joint infection: a retrospective study

L. Legout, X. Lemaire, S. N'guyen, H. Dezeque, C. Loez, M. Caillaud, E. Beltrand, H. Migaud, L. Dubreuil, Y. Yazdanpanah, E. Senneville (Tourcoing, Lille, FR)

Background: High clinical success rate has been reported in patients (pts) treated with prolonged linezolid therapy (PLT) for bone joint infection (BJI) but bone marrow toxicity, especially anaemia, occurred in up to 25% of pts. Recently, a 35% decrease in the serum linezolid concentration was observed after the administration of 600 mg of rifampin due to a hypothetic increase in intestinal secretion of linezolid.
Objective: To assess whether linezolid-rifampicin combination (LRC) therapy reduces bone marrow toxicity compared with linezolid monotherapy or other linezolid combinations in patients with BJI.
Methods: Medical charts for pts with BJI treated with linezolid for at least 4 weeks were reviewed. Frequency of bone marrow toxicity events was assessed in pts treated with LRC and in those treated with linezolid monotherapy or other linezolid combinations. Anaemia was defined as haemoglobin value < 9.0g/dl, leukopenia as a total leucocyte count $<4\times10^9$/L, and thrombocytopenia as a platelet count $<100\times10^9$/L.
Results: 94 pts of mean age 53.5 ±17 years (range 18–94) treated for BJI (devices infection = 37%, chronic osteomyelitis=33%) between 1999 and 2006 were eligible for the study. Comorbidities included diabetes mellitus (27.6%), alcoholism (9.6%) and chronic renal failure (6.4%). 43 pts (44.8%) were treated with LRC, 25 (26.6%) with linezolid monotherapy and, 28 (29.7%) with other linezolid combinations. Surgery was required in 75 pts (79.78%). Culture of intraoperative samples and bone biopsy (122 microorganisms) were positive in 91pts (96.8%) [(meticillin resistant *Staphylococcus aureus*: 38 (31%), coagulase negative staphylococci: 46 (37.7%), others Gram-positive bacteria: 21 (17.2%), Gram-negative bacilli: 12 (9.8%), anaerobes: 5 (4%)]. Polymicrobial infections were seen in 21 pts (22.34%). Demographic characteristics were comparable between pts treated with either LRC or other linezolid regimens. Anaemia was recorded in 5 of the 43 LRC pts (11.6%) and, in 22 of the 51 pts (43%) treated with other linezolid regimens ($p= 0.001$). The mean delay from onset of anaemia and initiation of linezolid therapy was 13.4 ±8.7 weeks in LRC pts and 9.5 ±4.3 weeks in the other pts ($p=0.001$). 21/27 (77.8%) had to stop linezolid therapy and 15 of them had to be transfused. No other haematological adverse events were recorded.
Conclusion: PLT for BJI resulted in less anaemia episodes when it was combined with rifampin than when it was used in either monotherapy or other combinations.

P825 Risk factors and surgical site infection in a tertiary care hospital in Greece

A. Masgala, G. Nikolopoulos, Z. Touloumis, V. Schizas, C. Dervenis, T. Kakavoulis (Athens, GR)

Objectives: To estimate the risk factors for surgical site infection (SSI) in the surgical wards of a tertiary care hospital in Greece.
Materials and Methods: In two surgical wards of 33 beds each, a total of 41 patients with surgical infections were recorded during the period 1/7/07 to 30/11/07. We applied logistic regression models to examine the effect of the following risk factors on the type of infection: underlying diseases (cardiac failure, diabetes mellitus, renal failure, respiratory failure, neoplastic disease, connective tisue disease, malnutrition, obesity, liver insufficiency), smoking, alcohol consumption, medications (chemotherapy agents, corticosteroids, others), American Society of Anesthesiologists (ASA) score, type of anaesthesia, type of surgery, duration of surgical procedure, postoperative time in Intensive Care Unit (ICU) and time on ventilator.
Results: Among 41 patients with surgical infections, 26 were males (63.41%) and 15 were females (36.59%) while the mean age was 62.02 years. Totally, 22 had SSI (53.66%), 3 had pneumonia (7.32%), 3 had bacteraemia (7.32%), 2 had intraabdominal abcesses (4.88%), 3 had pneumonia plus intraabdominal abcesses (7.32%), 1 had bacteraemia plus SSI (2.44%), 2 had central catheter infection plus SSI (4.88%), 1 had SSI plus intraabdominal abcess (2.44%), 1 had pneumonia plus bacteraemia plus SSI (2.44%), 1 had pneumonia plus SSI plus central catheter infection (2.44%), 1 had bacteraemia plus SSI plus central catheter infection (2.44%), and 1 had pneumonia plus bacteraemia plus SSI plus central catheter infection (2.44%).
Using logistic regression analysis, we found that only postoperative time in ICU or time on ventilator can increase almost 10 fold the risk of acquiring any surgical infection other than SSI (Odds ratio:10.8, 95% Confidence Interval:2.01–58.10).
Conclusion: More than half of the patients in this study experienced a surgical site infection. Postoperative time on ICU and time on ventilator affected significantly the type of infection.

P826 Arthroscopic knee surgery: postoperative wound infections, antibiotic prophylaxis and preoperative hair removal. Data from AMBU-KISS

E. Meyer, E. Ingenhoven, R. Babikir, M. Dettenkofer (Freiburg, Neuss, DE)

Objectives: In 2002, a database was set up within the context of the project AMBU-KISS (surveillance of surgical site infections

in ambulatory surgery) to document post-operative wound infections occurring in ambulatory surgical centres located in hospitals and medical practices. Reference data are compiled on internal quality assurance and contribute to the control of surgical site infections (SSI).

Methods: A SSI is diagnosed according to CDC criteria either during post-operative surveillance by the surgeon himself or by another doctor or family doctor. The reference data are made available to the participants in anonymous form every six months. Furthermore, AMBU-KISS participants were interviewed about perioperative prophylaxis and preoperative hair removal.

Results From 10/2002 to 6/2007, we received results from 101 centres performing arthroscopic knee surgery. A total of 71 infections occurred after 73,165 surgical interventions. The mean incidence was 0.08, i.e. 8 infections occurred after 10,000 operations. 40 centres completed the questionnaire. 36/40 participants removed the hair of their patients, mostly with razors (32/36) and immediately prior to surgery (31/36). 24/40 centres did not give perioperative prophylaxis, whereas 16/40 administered antibiotics for selected patients. 13/16 preferred 1st or 2nd generation cephalosporins as single shot (12/16) prophylaxis and applied them before incision (14/16). However, 4 centres administered antibiotics for 3–6 days post surgery or the evening before surgery (2/16).

Conclusions: The AMBU-KISS protocol is suitable for assessing and defining the magnitude of surgical site infections in ambulatory surgery, in which setting they were shown to be very low. However, there is still room for improvement with respect to the implementation of infection control guidelines. Guidelines do not recommend routine hair removal. If shaving is necessary for technical reasons, clippers instead of razors are recommended. More frequent use of broad spectrum prophylaxis than applying a single shot is not only useless but costly and may give rise to bacterial resistance. Generally, there is no evidence to support the use of antibiotic prophylaxis in arthroscopic knee surgery. Therefore, it is imperative that antibiotic prophylaxis be restricted to high-risk patients all the more in an ambulatory setting with very low infection rates.

P827 First case series of post-operative ocular infection due to *Streptococcus dysgalactiae* ssp. *equisimilis* in humans

S. Preziuso, J. Kaliamurthy, P.A. Thomas, V. Cuteri (Matelica, IT; Tiruchirapalli, IN)

Clinical infection due to *Streptococcus dysgalactiae* ssp. *equisimilis* (*S. equisimilis*), including primary bacteraemia, pneumonia, endocarditis, arthritis, and streptococcal toxic shock syndrome are increasing; however, there has hitherto been only one report of ocular infection. In the present report, infection due to *S. equisimilis* is described in three immunocompetent patients after ocular surgery and in one theatre nurse. The three patients had a history of uncomplicated small incision cataract surgery with posterior chamber intraocular lens implantation. They developed pain and reduced vision in the operated eye 48 hours after surgery. On examination the affected eyes revealed dense peripheral corneal infiltrates with exudates in the anterior chamber. Gram-stained smears of vitreous fluid samples revealed numerous Gram-positive cocci in pairs and short chains, culture of these samples grew beta-haemolytic streptococci provisionally identified as *Streptococcus dysgalactiae* ssp. *equisimilis* by biochemical methods. The identification was confirmed by PCR for a 16S rRNA sequence specific to the species *S. dysgalactiae* and for a sequence of the streptokinase precursor gene specific to human isolates of the subspecies *equisimilis*.

Intravitreal cefazolin and amikacin along with topical ofloxacin and tobramycin for a few days resulted in resolution of infection in the patients.

The organism was also isolated from a throat swab sample collected from a 35-year-old healthy nurse who had assisted at the three surgeries. The nurse did not give a history of systemic infection and had no signs of upper respiratory tract infection or other diseases.

This is the first case series of postoperative ocular infection due to *S. equisimilis*. The infection may have been transmitted during surgery or the healthy carrier (theatre nurse) may also have transmitted the infection. Epidemiology of this organism is probably undervaluated and antibiotic treatment without bacterial identification is often done. Bacterial culture and identification by PCR followed by antimicrobial sensitivity testing are recommended in order to better investigate the spread and pathogenic potential of *S. equisimilis* and to evaluate the risk of nosocomial infections due to asymptomatic carriers.

P828 The effect of 3rd generation cephalosporin use restriction on antimicrobial resistance and clinical outcomes among intensive care unit patients

Y.B. Seo, H.J. Cheong, W.S. Choi, J. Lee, J.Y. Song, W.J. Kim (Seoul, KR)

Objectives: The primary goal of this study was to evaluate the effect of 3rd-generation cephalosporin restriction policy on the changes of the antimicrobial usage among patients admitted to ICU. The secondary goal was to investigate the changes of meticillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococci (VRE) colonisation rate. The third aim was to analyse the differences of the isolation rate of MRSA, VRE, 3rd-generation cephalosporin resistant *Acinetobacter baumannii*, extended spectrum β-lactamase (ESBL) producing *Escherichia coli* and *Klebsiella pneumoniae* from clinical specimens between pre- and post-restriction period. The fourth aim was to estimate the impact on clinical outcomes of patients, including hospital day, infection-related mortality and medical expenses.

Methods: This study was conducted between February 2006 and January 2007: a cross-sectional study with intervention measures. All patients admitted to the intensive care unit were eligible for investigation. Third-generation cephalosporin use restriction program was implemented at March 20, 2006. We compared the differences of antibiotic usage, bacterial resistance and clinical outcomes of patients between 1 month before restriction and after 8 months.

Results: Seventy-four percent reduction in cephalosporin use was observed after 3rd-generation cephalosporin restriction. This was accompanied with increments of piperacillin-tazobactam (781.3%) and 4th-generation cephalosporin (417.1%) use. There was no significant difference in colonisation rate of MRSA and VRE. The isolation rates of MRSA, VRE, 3rd-generation cephalosporin resistant *A. baumannii*, ESBL-producing *E. coli* and *K. pneumoniae* from clinical specimens of sputum and urine did not show significant differenc, while those from blood and CSF were positively correlated with the usage of 3rd-generation cephalosporin. In clinical outcomes, the infection-related mortality and the length of hospotal stay were not different. However, medical expense was decreased significantly.

Conclusion: Despite the significant decrease of 3rd-generation cephalosporin consumption after restriction policy, the bacterial resistance patterns remained unchanged. In clinical outcomes, medical expense was decreased significantly. Restriction of 3rd-generation cephalosporin was demonstrated to be efficient in the view of decreased invasive infections and economics among patients of ICU.

P829 Benefit of a single preoperative dose of antibiotics in a Sub-Saharan district hospital: minimal input, massive impact

F. Saxer, A. Widmer, J. Fehr, I. Sooka, P. Kibatala, H. Urassa, H. Mshinda, R. Frei, T. Smith, C. Hatz (Basel, CH; Ifakara, TZ)

Objective: To evaluate the impact of a single shot preoperative antimicrobial prophylaxis in reducing the rate of surgical site infections (SSI) in an African hospital with very limited resources we implemented standardised guidelines with one dose of Amoxicillin/Clavulanic Acid within 2 hours prior incision.

Methods: In this rural district hospital in southern Tanzania an average of 150 surgical interventions is performed in two operating theatres every month. Ventilation is achieved by a defective air condition and open windows. Household soap is used for scrubbing.

Instruments are reprocessed by either heat (150°C for 1 h) or steam (134°C for 5min, temperature sensitive devices at 121 °C for 20min); a chemo-indicator is in use with every sterilisation process.

In a four month period in 2004, patients admitted for clean or clean-contaminated interventions had been included as pre-intervention group. The perioperative management differed depending on the surgeon. Patients admitted in the same setting in 2005 were enrolled as intervention group. They received one dose of 2.2g Augmentin® as intravenous infusion within 2 hours before incision. The substance was targeted at the bacteriologic pattern detected in SSIs of the pre-intervention group.
Patients were assessed daily and 30 days postoperative; in case of SSIs they received free diagnostic workup and treatment. Infections were identified according to the CDC classification; samples were analysed by Gram stain and agar (CHROMagar Orientation and CHROMagar *S. aureus*) in the local laboratory and the University Hospital Basel using standard methods. Data were reviewed by a senior infectious diseases specialist with full chart review.
Results: In the pre-intervention group 527 patients qualified for routine antimicrobial prophylaxis that was administered in 88% after incision and did not cover the expected pathogens to a large extent. One hundred and fourteen patients (21.6%) developed an SSI with 60% of detected pathogens being resistant to the administered antibiotics.
After implementation of the guidelines, the incidence of surgical site infections significantly decreased from 21.6% to 4% (11/276).
Conclusions: The implementation of a single shot antimicrobial prophylaxis dramatically decreased the rate of surgical site infections in a hospital with very limited resources. Such guidelines – though developed for industrialised countries – are even more effective in non-industrialised countries.

P830 Peritoneal dialysis-associated peritonitis: clinical features and predictors of outcome

D.P. Kofteridis, A. Valachis, K. Perakis, G. Papazoglou, K. Stylianou, E. Daphnis, G. Samonis (Heraklion Crete, GR)

Objectives: To identify epidemiological, clinical and microbiological factors affecting the outcome of patients with peritoneal dialysis (PD)-associated peritonitis
Materials and Methods: All of patients with PD-associated peritonitis, admitted to the University Hospital of Heraklion, Crete, Greece from 1990 to 2007 were identified and their charts were retrospectively studied.
Results: A total of 247 episodes of PD-associated peritonitis occurring in 82 patients have been evaluated. The median age of patients was 68 years (range 10–92); 51 (62%) were males. Seventy-four (90%) had an underlying condition such as cardiovascular disease 48 (59%), diabetes mellitus 26 (32%), heart failure 17 (21%), autoimmune disease 6 (7%) and cancer 2 (2%). There were 104 episodes (42%) of Gram-positive, 46 (19%) of Gram-negative, 13 (5%) of polymicrobial and 11 (4%) of fungal peritonitis, while in 73 episodes (30%) cultures were negative. Regarding outcome, patients were divided into 2 groups: those with curable and those with complicated episodes. Complicated episodes were characterised by death due to peritonitis, relapse or repeated episode, removal of catheter and need for temporary or permanent haemodialysis. There were 183 (74%) curable, while 64 episodes (26%) were considered complicated and included 11 (4.5%) deaths, 22 (9%) relapses, 13 (5%) repeated episodes and 18 (7%) catheter removals. Multivariate analysis revealed that presence of purulent exit-site infection ($P<0.001$), peritoneal dialysis effluent cell count >100/μl for more than 5 days ($P<0.001$), prior antibiotic use during the last 3 months ($P<0.05$) and low serum total protein level on admission ($P<0.05$) were independent predictors of complicated episodes.
Conclusions: Exit-site infection, number of days with the peritoneal dialysis effluent cells count >100/μl, prior antibiotic use and serum total protein level are potential predictors of outcome in PD-associated peritonitis and may distinguish high-risk patients. Further study is needed to determine whether an aggressive management of these high-risk patients could improve outcome.

P831 Infections in patients with head injury: a 6-year retrospective study

I. Kourbeti, J. Papadakis, D. Karabetsos, C. Neophytou, M. Filippou, A. Ioannou, M. Anastasaki, A. Vakis (Heraklion, GR)

Objectives: Infections in patients with traumatic brain injury (TBI) are associated with prolonged hospitalisation and adverse outcomes. The acknowledgement of the pre-disposing risk factors may help decrease the morbidity and mortality
We conducted a retrospective cohort study to determine the incidence, bacteriology and risk factors for development of infection after head injury
Methods: The records of patients >18 years old, admitted with head injury in Crete Univ Med Ctr between 1999 and 2005 were abstracted. Data were analysed with SPSS
Results: 877 events were analysed with a total of 338 surgeries. Burr hole was the most common procedure (28%). Males predominated (75.6%) and the median age was 40. Surgical site infections (SSI) developed in 11.2% of the patients that underwent surgery. Wound infection was the most common (53%). Meningitis/ventriculitis comprised 43% of the SSI. Coagulase negative staphylococci (CNS) predominated as pathogens
Ventilator Associated Pneumonia (VAP) in 7.4% of the entries and they were the most common infections other than SSI. Gram(–) bacilli predominated in VAP with *Acinetobacter* spp. being the most common
Risk factors for SSI surgery through sinus ($p<0.001$), CSF leak($p=0.01$), ICU stay ($p<0.001$), use of a dural substitute ($p=0.01$), drain placement and duration of drains, ICP placement ($p=0.01$) and concomitant infections ($p<0.001$). Development of meningitis was associated with surgery through sinus ($p<0.001$), ICU stay ($p<0.0001$), CSF leak ($p<0.05$), use of ventricular drains ($p<0.01$) and concomitant infections ($p<0.001$). SSI and meningitis were associated with prolonged hospitalisation but only meningitis with an increased mortality ($p<0.05$). In multivariate analysis surgery through sinus, ICU stay were associated with development of SSI and meningitis but only SSI with CSF leak
Conclusions: Infections are common in patients with head injury. Superficial and deep SSI are associated with prolonged hospitalisation and increased mortality. Some of the risk factors may be minimised by careful surgical technique and aseptic management of foreign devices. The type and sensitivities of the pathogens must be determined institution by institution for effective empirical treatment

Lower respiratory tract infection

P832 Human Rhinovirus: a role in adult LRTI?

H. Donaldson, J. Troughton, P. Coyle, S. Feeney, D. McAuley, R. McMullan (Belfast, UK)

Objectives: Human Rhinovirus (HRV) is a picornavirus often responsible for the "common cold". It has been associated with exacerbations of asthma and chronic obstructive pulmonary disease in adults and with bronchiolitis and pneumonia in children. However, there is limited information on HRV-associated lower respiratory tract infection (LRTI) in adults without chronic lung disease, partly due to few laboratories offering routine HRV detection in adults. The aims of this study were, firstly, to describe the epidemiology of LRTI associated with HRV in hospitalised patients, particularly, clinical outcomes in terms of chest consolidation, duration of hospital admission and mortality. Secondly, to compare these measures among patients with coexisting bacterial LRTI (HRV+bacterial), to those with HRV infection only.
Methods: Data were collected on 27 adult patients with respiratory secretions which tested positive for HRV who had been admitted to two University hospitals in Northern Ireland, between 2003 and 2006 with a primary diagnosis of LRTI. HRV was detected from respiratory secretions by a reverse-transcriptase polymerase chain reaction (RT-PCR). A bacterial isolate was defined as a positive result from at least one of the following: sputum culture; blood culture; atypical pulmonary

pathogen serology, legionella or streptococcal urinary antigen. Duration of hospital admission was expressed as geometric mean and interquartile range (IQ).
Results: Results are summarised in the table. There was no detectable significant difference between the patients groups in terms of age ($p=0.81$), sex distribution ($p=0.25$), presence of chest consolidation ($p=0.71$), duration of hospital admission ($p=0.46$), and mortality ($p=0.38$).

	Number of patients (M, F)	Mean age (years)	Consolidation present	Duration of admission (days)	Hospital mortality
Total cohort	27 (12, 15)	51.5	7 (25.9%)	13.2 (8.0, 16.0)	5 (19%)
HRV + bacterial	10 (7, 3)	52.8	3 (30.0%)	15.5 (8.8, 45.3)	1 (10%)
HRV only	17 (8, 9)	50.7	4 (23.5%)	12.0 (6.9, 16.0)	4 (24%)

Conclusions: Patients with a LRTI who isolated HRV only, had similar clinical outcomes in terms of duration of hospital stay, chest consolidation and mortality compared with patients with a bacterial LRTI who co-isolated HRV. Although the dataset is small, these findings suggest that HRV may have a role in the aetiology of LRTI in hospitalised adults.

P833 Inhaled corticosteroids increase the risk of pneumonia? A further step in a population-based study

J. Almirall, I. Bolibar, M. Serra-Prat, J. Roig, I. Hospital, E. Carandell, M. Agustí, P. Ayuso, X. Balanzó, A. Torres on behalf of PACAP Group

Aim of the study: To identify if the inhaled treatment general and inhaled corticoids in particular are risk factor for community-acquired pneumonia (CAP).
Patients and Methods: This was a population-based case-control study with a target population of 859,033 inhabitants >14 years of age. All patients with confirmed radiographic CAP presented over 1-year were prospectively registered ($n=3336$). Each case of confirmed CAP was frequency matched to a control subject ($n=3326$). Then we selected all chronic bronchitis or asthma diagnosis (CAP patients= 473 and controls=235) in order to compare the inhaler treatments. Then we adjusted for illness severity considering the use of oxygen therapy.
Results: Multivariable analysis including health habits, household and work circumstances, clinical conditions and comorbidities, and oral treatments, confirmed IT as independent risk factor of CAP. Among chronic bronchitis or asthma patients, IT remained a significant risk factor of CAP with a dose-related relationship, particularly when steroids or plastic pear-spacers were used (see table).

Variable	Cases (n = 473)	Controls (n = 235)	OR	95% CI	P value	OR (adjusted per O_2)	95% CI
Age: mean (SD)	59.6 (20.0)	60.9 (20.7)	0.99	0.99–1.00	0.99	–	–
Sex (% women)	189 (40.0%)	103 (43.8%)	0.85	0.62–1.17	0.324	–	–
Inhalers	183 (38.7%)	69 (29.4%)	1.52	1.08–2.12	0.015	1.43	1.00–2.03
Inhaled steroids	13 (4.3%)	1 (0.6%)	7.44	0.96–57.39	0.05	1.70	1.09–2.68
Inhaled beta-agonists	88 (23.3%)	43 (20.6%)	1.17	0.78–1.768	0.451	1.08	0.70–1.64
Inhaled anticholinergic drugs	84 (22.5%)	21 (11.2%)	2.29	1.368–3.83	0.002	2.17	1.26–3.75
Puffs/day							
1–6	77 (16.5%)	38 (16.5%)	1.16	0.75–1.79	0.002	1.11	0.71–1.74
6–10	41 (8.8%)	17 (7.4%)	1.38	0.76–2.51		1.32	0.72–2.42
>10	58 (12.4%)	9 (3.9%)	3.68	1.78–7.64		3.31	1.52–7.23
Inhalers							
Without spacer device	129 (28.8%)	55 (24.3%)	1.39	0.96–2.02	0.013	1.27	0.87–1.87
With spacer device	54 (12.1%)	14 (6.2)	2.28	1.23–4.25		2.02	1.06–3.88

Conclusion: IT is a significant and independent risk factor of CAP in the general population and among patients with chronic bronchitis or asthma, particularly when medication contained steroids or plastic pear-spacers were used.

P834 Use of ACE inhibitors and risk of community-acquired pneumonia

P. Rafailidis, D. Matthaiou, I. Varbobitis, M. Falagas (Athens, GR)

Objectives: The administration of angiotensin-converting enzyme (ACE) inhibitors has been suggested as an alternative strategy for lowering the risk of community-acquired pneumonia (CAP) in the elderly, especially in patients with neurological and cerebrovascular comorbidity.
Methods: We critically examined the relevant data from studies regarding the impact of ACE inhibitors in lowering the risk of CAP and/or mortality due to CAP in the elderly. We searched in PubMed, Cochrane database and references of initially retrieved articles, and in http://clinicaltrials.gov for ongoing trials.
Results: We identified 285 evaluable studies. Eleven studies met the inclusion criteria and were evaluated further, of which 6 were prospective studies, 2 randomised controlled trials, and 3 retrospective studies. All studies including patients of Asian origin demonstrated a statistical significance in favour of ACE inhibitors. This was not the case, though, for studies including patients of non-Asian origin.
Conclusion: The available data suggest that ACE inhibitors may contribute to the reduction of the risk of CAP. Nevertheless, the clinical data are scarce and mainly comprise of studies including patients of Asian origin. Since there seem to be differences regarding the genetic polymorphism of ACE among patients of different origin, future studies may need to incorporate relevant genetics data that may help clarify the role, if any, of ACE inhibitors in prevention of CAP.

P835 Diabetes, glycaemic control and risk of hospitalisation with pneumonia: a population-based case-control study

J.B. Kornum, R.W. Thomsen, A. Riis, H. Lervang, H.C. Schønheyder, H.T. Sørensen (Aalborg, Aarhus, DK)

Objective: To examine whether diabetes is a risk factor for hospitalisation with pneumonia and to assess the impact of HbA1c level on such risk.
Methods: In this population-based case-control study we identified patients with a first-time pneumonia-related hospitalisation between 1997 and 2005, using healthcare databases in Northern Denmark. For each case, ten sex- and age-matched population controls were selected from Denmark's Civil Registration System. We used conditional logistic regression to compute odds ratios (ORs) as a measure of relative risk (RR) for pneumonia-related hospitalisation among persons with and without diabetes, controlling for comorbidity, alcoholism-related conditions, pre-admission use of antibiotics and immunosuppressants, marital status, presence of small children in the household, and degree of urbanisation.
Results: The study included 34,239 patients with a pneumonia-related hospitalisation and 342,390 population controls. The adjusted RR for pneumonia-related hospitalisation among persons with diabetes was 1.26 (95% confidence interval (CI) 1.21–1.31) compared with nondiabetic individuals. The adjusted RR was 4.43 (95% CI 3.40–5.77) for patients with Type 1 diabetes and 1.23 (95% CI 1.19–1.28) for patients with Type 2 diabetes. Diabetes duration $\geqslant$10 years increased the risk of a pneumonia-related hospitalisation (adjusted RR 1.37; 95% CI 1.28–1.47). Compared with persons without diabetes, the adjusted RR was 1.22 (95% CI 1.14–1.30) for diabetic persons whose HbA1c level was <7%, and 1.60 (95% CI 1.44–1.76) for diabetic persons whose HbA1c level was $\geqslant$9.
Conclusions: Type 1 diabetes, and to some extent Type 2 diabetes, are risk factors for a pneumonia-related hospitalisation. Poor long-term glycemic control among patients with diabetes clearly increases the risk of hospitalisation with pneumonia.

P836 Specific clinical determinants of community-acquired Legionnaires' disease associated with the Paris or Lorraine endemic strains

A. Duclos, C. Ginevra, S. Jarraud, C. Campese, D. Che, J. Etienne, P. Vanhems (Lyon, Saint Maurice, FR)

Objectives: Legionnaires' disease (LD) is primarily caused by *Legionella pneumophila* sporadic or endemic strains. The Paris and the Lorraine strains are the main endemic strains in France. The objective was to explore the clinical determinants of infection associated with these two strains in patients with community acquired LD.
Methods: A double nested case-control study based on data from the French national surveillance network of incident LD between 1998 and 2005 was performed. All notified patients with a community acquired LD based on X-chest ray of pneumonia and definite biological diagnosis, were included. Cases were patients infected with Paris or Lorraine strains, whereas controls were those infected with sporadic strains. Epidemiological and clinical factors associated with Paris or Lorraine strains were assessed by adjusted odd-ratios, according to multivariate logistic regression models.
Results: Study population included 883 persons for whom infection occurred with sporadic (n = 364), Paris (n = 37) or Lorraine (n = 32) strains. Compared to patients infected with sporadic strains, female gender (adjusted odd-ratios [OR], 2.47, 95% confidence interval [CI], 1.44 to 4.25), ageing (OR for one year increase in age, 1.03, 95% CI, 1.01 to 1.05), treatment with steroids (OR, 3.47, 95% CI, 1.84 to 6.52) and history of hemopathy or cancer (OR, 1.90, 95% CI, 1.00 to 3.59) were more frequent among those infected with Paris strains. Compared to patients infected with sporadic strains, smoking (OR, 2.09, 95% CI, 1.11 to 3.96), diabetes (OR, 2.35, 95% CI, 1.12 to 4.91) and the 2004–2005 period of LD notification (OR, 8.30, 95% CI, 1.12 to 60.60) were independently associated among those infected with Lorraine strains.
Conclusion: Several patient characteristics were associated with endemic strains of *Legionella pneumophila*. These determinants were different for patients infected with Paris or Lorraine strains. These results observed in France should be extended to other areas to corroborate the potential link between the host susceptibility and a peculiar *Legionella pneumophila* strain background.

P837 Molecular epidemiology of *Legionella pneumophila* in Comunidad Valencia (Spain)

M. Coscolla, F. Gonzalez-Candelas (Valencia, ES)

Objectives: The main objective is to investigate the epidemiology of *Legionella* strains in a Spanish region that includes an area where legionellosis has become almost endemic, with continuous bouts of sporadic cases and several outbreaks affecting tens even hundreds of people, by using molecular and phylogenetic methods. Given that the culture efficiency of this bacterium from respiratory samples is very low, a minor objective was to obtain sequences derived from infected sputum without culturing it.
Methods: We have amplified and sequenced six protein coding loci and 3 intergenic regions for which we developed primers anchored in flanking conserved genes. Sequences of these nine markers were obtained in a dataset including about 100 clinical and more than 150 environmental samples, some related and others not to the clinical isolates, collected along several years. Environmental samples were sequenced from pure cultures while a semi-nested PCR approach was used to directly amplify and sequence DNA from sputum samples. When available, cultured clinical samples were also analysed. The obtained nucleotide sequences were used to infer evolutionary, population genetics and epidemiological relationships among them.
Results and Conclusions: Comparisons among sequences derived from isolates from the same patient (cultured isolate and DNA from sputum) were 100% identical, so amplification and sequencing from respiratory samples without culturing is feasible and more efficient.
Occasionally, clinical isolates from the same outbreak were very similar but not completely identical which, given the evolutionary rates in this bacterium, might be explained having different origins despite a common epidemiological pattern. For those cases with clinical and presumed environmental source isolates, we consistently observed lack of congruence between samples from both origins, probably because the origin of the infection was not actually identified. Therefore, the molecular analysis could complement the epidemiological investigation in order to correctly identify the environmental sources of infections.
Although we have detected a large genetic diversity in both clinical and environmental samples from the Comunidad Valenciana, our results indicate the existence of a predominant clone among clinical isolates which is the main responsible for recurrent outbreaks in a restricted area where legionellosis has become almost endemic.

P838 Penicillins vs. trimethoprim-based regimens for acute bacterial exacerbations of chronic bronchitis: a meta-analysis of randomised controlled trials

I. Korbila, K. Manta, I. Siempos, G. Dimopoulos, M. Falagas (Athens, GR)

Objectives: Semi-synthetic penicillins (SSP) (amoxicillin, ampicillin, pivampicillin) and trimethoprim-based regimens [TMP, co-trimoxazole (TMP/SMX), TMP/sulfadiazine) have been used for the treatment of patients with acute bacterial exacerbations of chronic bronchitis (ABECB).
Methods: We searched MEDLINE, Current Contents, and the Cochrane Central Register of Controlled Trials to identify and extract data from relevant RCTs for a meta-analysis comparing the effectiveness and toxicity of penicillins with trimethoprim-based regimens.
Results: Out of 134 RCTs identified in the search, 5 RCTs, involving 287 patients, were included in the analysis. There was no difference between patients with ABECB treated with SSP compared to those treated with TMP, alone or in combination with a sulfonamide, regarding treatment success [intention to treat (ITT) patients: 262, odds ratio (OR)=1.68, 95% confidence intervals (CI) 0.91–3.09, clinically evaluable (CE) patients: 246, OR=1.59, 95% CI 0.79–3.20] or drug-related adverse events in general (186 patients, OR=0.37, 95% CI 0.11–1.24), diarrhoea, skin rashes, or withdrawals due to adverse events (179 patients, OR=0.27, 95% CI 0.07–1.03).
Conclusions: Based on limited evidence leading to wide confidence intervals of the estimated treatment effects, SSP and trimethoprim-based regimens seem to be equivalent in terms of effectiveness and toxicity for ABECB.

P839 Treatment of patients hospitalised with community-acquired pneumonia using moxifloxacin versus levofloxacin and ceftriaxone: comparing costs from the hospital and social insurance perspectives

A. Lloyd, A. Holman, T. Evers (London, UK; Wuppertal, DE)

Objective: To estimate the costs to German hospitals and statutory health insurers of managing patients hospitalised with CAP and treated with moxifloxacin (MXF) or a combination of levofloxacin plus ceftriaxone.
Methods: To ascertain costs from a hospital perspective, drug costs were taken from the Rote Liste; costs for hospitalisation were taken from a recent publication that reported bottom-up costing for the components of CAP management in 22 German hospitals; and costs for investigations and procedures were obtained using the German hospital fee scale, used for private patients. To estimate costs from a social insurance perspective, diagnosis-related group (DRG) codes including hospitalisation, medication, diagnostic and therapeutic procedures were used. Data on individual patient resource use were taken from a prospective, randomised, double-blind study of adults with CAP requiring hospitalisation and parenteral antibiotic therapy. Patients received sequential treatment with IV/oral antibiotics (either MXF [N=368], or comparator [N=365]) and for 7–14 days.

Results: As the percentage of patients reporting clinical response (MXF, 80%; comparator, 84%) met criteria for clinical equivalence, cost-minimisation analysis was appropriate. From a hospital perspective, mean per-patient costs were €2,190 (95% CI: €1,954, €2,463) for the MXF group, and €2,619 (95% CI: €2,422, €2,832) for the comparator group, with a between-treatment difference of –€430 (95% CI: –€740, –€138). From an insurer perspective mean per patient costs were €2,683 (95% CI: €2,576, €2,798) for the MXF group, and €2,669 (95% CI: €2,581, €2,768) for the comparator group, with a between-treatment difference of –€14 (95% CI: –€127, €152). Net income to the hospital, defined as the difference between the insurer payment and hospital cost, was €493 per patient for the MXF group (95% CI: €304, €664) and €50 (95% CI: –€110, €201) for the comparator group.
Conclusions: From a hospital perspective, treatment with MXF was significantly less costly than treatment with the comparator, with no clinically significant difference in outcomes. There was no significant difference in cost from an insurer perspective. This analysis found that compared with comparator, MXF reduced drug cost, had no significant effect on other costs and therefore reduced the per-patient cost of managing CAP.

P840 Excess death attributable to influenza in the Czech Republic in 1986–2006

J. Kyncl, B. Prochazka, M. Havlickova (Prague, CZ)

Objectives: Annual influenza epidemics differ in duration and magnitude. Influenza infection is underestimated, being easily mistaken for one of acute respiratory infections (ARI) since showing similar clinical symptoms. The aims of this study are to find correlation between mortality and influenza morbidity and to model mortality in different weeks of the year outside the influenza epidemic.
Methods: Data on daily deaths from all causes and deaths from diseases of the circulatory system in Czech Republic were available for 1986–2006 (altogether 2 317 522 and 1 267 718 deaths reported, respectively). Data on the incidence of influenza and other ARI were taken from the surveillance programme. The weeks in which ARI morbidity exceeded the epidemic threshold and at the same time, circulation of influenza virus among the population was reported by the National Influenza Centre, were considered as influenza epidemic weeks. Analysis was based on the assumption that outside the epidemic periods, deaths are distributed according to the Poisson distribution with a linear trend depending on time and with periodic behaviour during the year. The morbidity rate is only expected to increase in the epidemic compared to non-epidemic period.
Results: When comparing the weekly morbidity from acute respiratory illnesses and weekly mortality for all causes of death, the peaks of these two parameters almost overlap. In the epidemic period (152 weeks) 28.3% of findings were above the unilateral 95% tolerance limit of the model, compared to the non-epidemic period (926 weeks) with only 4.0% of findings above this limit. The mean estimated excess of annual deaths from all causes was 1922 (18.66 per 100 000). The median of deviations of the estimated number of deaths from the actual number of deaths is negligible at 11.9 for the non-epidemic period, being equal to 129.8 for the epidemic period, $p<0.001$. Similar results were found for deaths from diseases of the circulatory system accounting for 54.7% of all deaths in the study period.
Conclusions: The presented results confirm clearly and unambiguously excess in death rates during the influenza epidemic periods, depending on the duration and magnitude of the epidemic. The mean annual excess rate for Czech Republic is 1.7% population, the major part of this rate being attributable to influenza. Vaccination against influenza proved both effective and cost-effective and therefore is to be recommended as the most important preventive measure.

P841 Whooping cough in Catalonia, Spain

M. Romero, M. Quesada, N. Cardenosa, G. Carmona, M. Oviedo, G. Codina, Á. Domínguez (Barcelona, ES)

Objective: to estimate the incidence of pertussis among general population, and to identify individuals with pertussis among the contacts of children with confirmed pertussis.
Methods: From April 2003 to April 2004, 465 pertussis-suspect-cases were reported from voluntary healthcare centres all over Catalonia. Pertussis infection was confirmed by means of culture and/or polymerase chain reaction assay of the nasopharyngeal specimens. We recorded a detailed cough history at presentation, as well as we asked parents for details of their child's immunisations and verified any information they gave from the parent held record or medical notes. A descriptive analysis was carried out of the demographic characteristics, clinical history, complications, treatment, diagnostic methods, epidemiologic information and vaccination.
Results: During the study period, there were a total of 71 laboratory confirmed cases of B. pertussis infection. There were 30 males and 41 females. Most (n = 31; 43.7%) of the patients were less than 1 year of age. Seven percent (5) of patients were between 1–6 years, 22.5% (16) were between 7 and 14 years and 26.8% (n = 39) were older than 14 years of age. Forty one cases (60%) presented paroxysmal cough, 22 (32%) post-tussive vomiting, 18 (26%) inspiratory whoop and 17 (25%) apnoea. The vaccination status was not known for 24 (33.8%) patients. Of the total vaccine status documented cases, 31 (66%) patients were vaccinated. Fifty patients (70.4%) were considered the index or co-index cases, 47 of them (94%) were children under 15 years old. Pertussis was confirmed in 18.3% (13/71) of the contacts of 50 index cases. Among these contacts identified as a pertussis case, 61.5% (8/13) were older than 14 years of age. These contacts were father (6 cases), mother (6), brother (2), sister (2), grandmother (2), others (3).
Conclusion: In this sample of cases of whooping cough arising in the highly vaccinated population of Catalonia, the overwhelming majority of cases were infants less than 1 year of age and older adults. Healthcare professional should be in alert to identify new cases of pertussis. The early recognition of pertussis index cases by healthcare professionals, the treatment of the cases and prophylaxis of the contacts is fundamental to control an outbreak in the community.

P842 Pertussis surveillance in one geographic area of Catalonia, 2003–2007

M.R. Sala Farré, C. Arias Varela, A. Recasens Recasens, G. Codina (Terrassa, Barcelona, ES)

Objectives: In Catalonia pertussis suspected cases should be reported to the Epidemiological Surveillance Unit. In 2003 a pilot surveillance program was undertaken, suspected clinical cases should be laboratory confirmed. Means to confirm cases were offered to public health services, mainly urgency wards. This report summarises the epidemiological factors associated with pertussis confirmed cases in one geographic area of Catalonia (Vallès Occidental) with 836077 inhabitants. Incidence rates and trends are described.
Methods: Clinical symptoms to suspect pertussis included cough for two weeks, and at least one of the following symptoms: dyspnea, paroxysm coughing, inspiratory whoop or post-tussive vomiting. Confirmation of cases requires PCR testing of nasopharyngeal fluid or Bordetella pertussis (BP) culture or to be epidemiologically linked to a laboratory confirmed case. Samples are analysed on a central laboratory of Hospital of Vall Hebron in Barcelona. Epidemiological data and vaccination status had been collected individually from all cases. Correct vaccination status was evaluated according to the Catalonia vaccine schedule and the age of each case.
Results: During the 2003–2007 period 127 confirmed cases were reported. Higher incidence was in 2003 and 2007 (until November) with 6.4 cases/100000 inhabitants and 5.6 cases/100000 inhabitants, respectively. Cases were more frequent on children under one year (35%)

and among 10–14 years (19%) but 30–39 years old cases were 14%. Most cases have received the doses of BP vaccine recommended according the age (47%). Two cases died (1.6% lethality rate), both had one month of live. PCR were more sensitive when it was done at the first days of disease.

Conclusion: The predominance of paediatric cases can be a real incidence of cases, it may be to an increased awareness of pertussis by paediatric physicians or typical symptoms of BP infection in children; or it may be a combination of all these factors. The role of cases on vaccinated patients should be taken into account to evaluate the vaccination strategies.

P843 New insights in determining the aetiology of severe community-acquired pneumonia and its implications

N. Poblet-Mas, M. De la Torre, J.M. Sirvent, L.J. Garcia-Gil (Girona, ES)

Objectives: Severe community-acquired pneumonia (SCAP) can be caused by different bacteria which show similar clinical presentations. *Legionella pneumophila* (LP) can be difficult to diagnose and its prevalence might be underestimated. The main goals of this work were:

1. To evaluate the aetiology of SCAP, the prevalence of the aetiologic agents and its relationship with the clinical manifestations and the risk factors.
2. To assess the use of a new PCR method specific for LP as an analysis of routine.

Methods: A total of 256 specimens (BAL, blood and urine) from 96 patients (66 with SCAP and 30 controls) admitted in the Intensive Care Unit (ICU) were analysed, from December 2004 to November 2007. Etiological agents were assessed simultaneously by culturing, by urinary antigen test (UAT) and by PCR for LP. Kendall's Tau-b correlation, Mann-Whitney and Kruskall-Wallis tests, and Fisher's Chi-square were performed, using as dependent variables SCAP patients or LP-positives by PCR. Thirty-one independent variables were analysed, twenty-three describing symptoms, seven for risk factors and one for the causative agent. The level of significance was set at P<0.05.

Results: The most prevalent pathogen was LP (45.5%), followed by *Streptococcus pneumoniae* (25.8%) and others (8.2%). In 20.5% of the patients no aetiologic agents were detected. Polymicrobial infections were found in 24.2% of the patients with SCAP. LP-positives obtained by PCR were significantly (P<0.001) higher than those obtained by UAT. Smoking (P<0.05) and respiratory diseases (P<0.01) were identified as risk factors. On the other hand, fever, cough, fatigue, dyspnea, sputum, tachypnea, pulmonary shunt and infiltrate, amongst others, were symptoms of SCAP (P<0.005). Significant differences between SCAP and control patients (P<0.05) in the ICU length of stay were only observed when the infection was polymicrobial. Although a significant correlation (P = 0.001) was found between SCAP and LP positives by PCR, no correlation was observed (P>0.05) between SCAP and LP positives by UAT.

Conclusions:

1. The significant symptoms and risk factors found in this study should be taken into account when diagnosing and selecting the initial antibiotic therapy.
2. Polymicrobial infections present a worse prognosis and more agressive clinical evolution.
3. Urinary antigen test is not sensitive enough to determine SCAP positives, while PCR is a better and more powerful tool.

P844 CAPNETZ: Data on clinical efficacy of antibiotic therapy and mortality of CAP in Germany

T. Welte, O. Burkhardt, R. Marre, N. Suttorp for the CAPNETZ Study Group

Objectives: Because of the medical and economic impact of community-acquired pneumonia (CAP), the Federal Ministry for Education and Research (BMBF) has, since 2001, been financing a network on CAP (CAPNETZ). CAPNETZ was founded to gain new insights into pathogenesis, particularly on pathogen-host interactions, to improve actual care in this area in Germany.

Methods: CAPNETZ integrates components of health research as well as clinical and basic research (horizontal network) on one hand and supports cooperation among general practitioners, community hospitals and universities (vertical network). The network partners report each suspected case of pneumonia to the local clinical centre of CAPNETZ. In case of CAP confirmation all clinical and microbiological data are documented.

Results: By the end of 2006, a total of 5,965 patients had been included in CAPNETZ of whom 1807 were out-patients and 4,158 were in-patients. The mean mortality was 8.2%. A further 5.8% of the patients died within the subsequent 5 months of observation after the cure of CAP. In spite of optimal conditions, an evaluable sputum sample could only be obtained from about half the patients. Usually a throat swab or nasal rinse was obtained for virus or mycoplasma diagnosis and urine was provided for antigen diagnosis (legionella and pneumococci). Even in most cases with sputum no causal pathogen could be found. *S. pneumoniae* was the most important pathogen, followed by *H. influenzae* and *M. pneumoniae*. With a prevalence of ca. 3%, legionella were rare. Nevertheless, they were linked to marked excessive mortality, emphasising the importance of performing a urine antigen test if there is a clinical suspicion of legionella. With a prevalence of about 3%, infections with Enterobacteriaceae were rare and primarily occurred in the risk group of very old and comorbid patients and patients from nursing homes. The mortality of these patients was 8-fold higher than in patients from a domestic environment. For the older patients (> 65 years), survival was highly dependent on the adequate primary antibiotic therapy. For this group (CRB-65 > 2), moxifloxacin was superior to β-lactam antibiotics. For patients with less severe disease (CRB-65 0 and 1), antibiotics like ampicillin were as effective as broad spectrum antibiotics.

Conclusion: The CAPNETZ data confirm the importance of pneumococci in CAP. The more severe cases benefit notably from an antibiotic therapy with moxifloxacin.

P845 The performance of CURB-65 in community-acquired pneumonia deteriorates with increasing age

M.J. Parsonage, D. Nathwani, P. Davey, G. Barlow (Hull, Dundee, UK)

Background: CURB-65 has been validated as a predictor of mortality in community-acquired pneumonia (CAP) (Lim et al. Thorax 2003) and is recommended by the British Thoracic Society (BTS) and Infectious Diseases Society of America (IDSA) CAP guidelines to guide management decisions. There has been concern about the performance of CURB-65, however, in older adults (Myint et al, Age and Ageing 2006).

Objectives: To assess and compare the performance of CURB-65 in different age groups.

Method: Retrospective analyses of data prospectively collected for a CAP quality improvement study were performed (Barlow et al. Thorax 2007). Patients were stratified into four age-based cohorts: 16–64years (Group 1), 65–74years (Group 2), 75–84years (Group 3), and >85years (Group 4). For each age cohort, 30-day mortality was stratified by CURB-65 score. Sensitivity, specificity, positive predictive value, negative predictive value, and area under the receiver operator curve (AUROC) were then calculated. Statistical analyses were performed by SPSS (version 12) with a p-value of <0.05 taken to indicate statistical significance.

Results: 428 patients were included in the study (Group 1 = 132, Group 2 = 92, Group 3 = 128, Group 4 = 76); 53% female. Across the groups, there were significant differences in social circumstances, oximetry <92%, urea >7 mmol/l, new confusion, chronic illness, ITU admission and mortality. In patients with non-severe CAP (defined as CURB-65 = 0 to 2), 30-day mortality was 3% in Group 1 compared to 6%, 13%, and 27% in Groups 2 to 4, respectively. At the current cut-off of >3, sensitivity and specificity were 0.33 and 0.98 in Group

1, respectively, 0.77 and 0.62 in Group 2, 0.79 and 0.5 in Group 3, and 0.65 and 0.48 in Group 4. In Group 1, sensitivity and specificity were highest at a cut-off of >2 (1.0 and 0.83, respectively). AUROC was 0.93 (95% CI 0.88 to 0.99, p<0.001) in Group 1 versus 0.74 (0.58 to 0.90, p = 0.005) in Group 2, 0.74 (0.64 to 0.83, p<0.001) in Group 3, and 0.59 (0.46 to 0.73, p = 0.2) in Group 4.
Conclusion: Misclassification as non-severe CAP (CURB-65 = 0 to 2) of patients who subsequently died increased across the age cohorts. The performance characteristics of CURB-65 deteriorated with increasing age. Clinicians should interpret CURB-65 scores in elderly patients with caution, especially in those >75years. In those <65years, a score >2 may be a better indicator of severe CAP.

P846 The time to first antibiotic dose does not predict early clinical failure in severe community-acquired pneumonia

A.H.W. Bruns, J.J. Oosterheert, E. Hak, I.M. Hoepelman (Utrecht, NL)

Objectives: The time to first antibiotic dose (TFAD) has been raised as an important performance indicator in patients (pts) suspected of community-acquired pneumonia (CAP). However, the advice to minimise TFAD to 4 hours (4 h) is only based on retrospective database studies. Moreover, adopting TFAD as performance indicator may lead to prioritisation of pneumonia pts to others and unnecessary treatment for pts who ultimately receive a differential diagnosis, contributing to an increase in antibiotic (AB) use, resistance and costs. Therefore, we studied the effect of minimising TFAD on early clinical failure in a prospective setting.
Methods: Pts admitted because of severe CAP without previous AB treatment to our university hospital, were prospectively followed. On admission, pts' medical data and TFAD were recorded. Appropriate AB therapy was defined as all identified pathogens being susceptible for the initiated antibiotics. Early clinical failure was defined as a respiratory rate >25/min, peripheral oxygen saturation <90%, partial pressure of arterial oxygen <60 mmHg, haemodynamic instability or altered mental status on day 3 of hospitalisation. Multivariable assessment of factors predictive for early clinical failure was performed.
Results: 166 pts (mean PSI 108.8±24.1; age 67.2±14.5 year) were included. Overall, median TFAD was 3 h12min. In 100 pts (60.2%) TFAD was <4 h (median 2 h23min) and in 66 pts (39.8%) >4 h (median 5 h17min). No other significant differences were observed between both groups. In 82 pts (49.4%) aetiology could be established. Of these, 68 pts (84.1%) received appropriate AB therapy. 24 pts (26.4%) with TFAD <4 h had early clinical failure, as compared to 22 pts (35.5%) with TFAD >4 h (Odds Ratio (OR) 0.7; 95% CI 0.3–1.3; p= 0.22). In addition, after correction for pneumonia severity and appropriateness of AB therapy, no favorable effect of TFAD <4 h was found (p = 0.30). Furthermore, no time-effect relation could be identified in TFAD and early clinical failure (corr. 0.14; p>0.05). In multivariate analysis not TFAD but an arterial pH <7.35 on admission (OR 5.7; 95% CI 1.3–25.3), confusion on admission (OR 3.4; 95% CI 1.5–7.6) and *Staphylococcus aureus* infection (OR 7.2; 95% CI 1.3–39.6) were independently associated with early clinical failure (P<0.03).
Conclusions: Clinical parameters on admission other than TFAD predict early clinical failure in severe CAP. Therefore, implementation of TFAD as performance indicator may not be desirable.

P847 Evaluation of a new immunochromatographic assay for the detection of *Legionella* antigen in non-concentrated and concentrated urine samples

S. Blanco, A. Lacoma, C. Prat, L. Haba, L. Fuenzalida, I. Latorre, J. Dominguez (Badalona, ES)

Objectives: The aim of the present study was to evaluate the sensitivity and specificity of a new ICT: Uni-GoldTM *Legionella* Urinary Antigen (Trinity Biotech, Ireland) against the Binax Now *Legionella* test in non concentrated (NCU) and concentrated (CU) urine samples.
Methods: The samples tested were grouped into 3 categories;
Group 1: 80 NCU and CU samples from patients with pneumonia caused by *L. pneumophila*. Legionnaire's disease was diagnosed by isolating *L. pneumophila* from respiratory specimens and/or by serology and/or by urinary antigen detection (Bartels EIA).
Group 2: 38 NCU and 26 CU samples from patients with pneumonia of other aetiologies and also 22 NCU and 19 CU samples from patients with bacteraemia from a non-respiratory focus.
Group 3: 50 NCU and 20 CU samples from patients with urinary tract infections, with no signs of pneumonia.
Results: The Uni-GoldTM LUA test detected *Legionella* Urinary Antigen in 51/80 NCU samples from Group 1 patients (63.75% sensitivity). Binax Now test detected *Legionella* in 54/80 NCU samples from group 1 patients (67.50% sensitivity). Both tests were all negative for urine samples from Group 2 and 3 patients (100% of specificity). The overall concordance of the tests for NCU was 89.42% (k 0.961, SE: 0.023). (p: 0.083).
After concentration of the urine samples, Uni-GoldTM detected 76/80 (95% sensitivity) and Binax Now 78/80 (97.5% sensitivity) of the Group 1 samples. The specificity was 95.4% for Uni-GoldTM LUA and 100% for Binax Now. The overall concordance of the tests for CU was 96.5% (k 0.931, SE: 0.031). (p: 0.655).
Conclusions: UniGold test is a technique simple to perform, and the results are obtained in 15 minutes. Unigold when is compared to Binax Now doesn't show statistically significant differences. The concentration of antigen present in urine by ultrafiltration increased the sensitivity.

P848 Long-term course of clarithromycin for the treatment of stage II COPD patients with frequent exacerbations

K. Zykov, A. Averianov, E. Shmelev, A. Tsoi, A. Rvatcheva, O. Brodskaya, A. Chuchalin (Moscow, RU)

It was shown that standard courses of antibiotic treatment of exacerbation of chronic obstructive pulmonary disease (COPD) with macrolides or β-lactams have clinical benefits and may also reduce the frequency of further exacerbations. But the data about the long-term courses of macrolide treatment are still controversial.
The aim of the study was evaluate the safety and efficacy of long-term course of clarithromycin in comparison with standard course of amoxicillin/clavulanate potassium for the treatment of stage II COPD patients with frequent exacerbations.
Methods: 51 patients (32 male and 19 female) with exacerbation of stage II COPD were enrolled in randomised parallel-group multicentre trial to compare the efficacy of course of clarithromycin (CLA)(Fromilid, KRKA, Slovenia)with standard course of amoxicillin/clavulanate potassium (AMC) tablets (Amoksiklav, Lek d.d., Slovenia). All patients (mean age 57.3±1.1 years, smoking history 34.1±1.6 pack/years, FEV1 50.2±1.8 of predicted) had frequent exacerbations (3 or more per year)of COPD. *Chlamydophila pneumoniae* IgG antibodies in diagnostic titers were found in 70.5% patients. After randomisation 25 patients of AMC group received 625 mg of AMC three times a day during 10 days. 26 patients of CLA group were treated with 500 mg of CLA twice daily during 10 days then 250 mg once daily during 50 days. The follow-up period was 12 months. The study was conducted according to the GCP rules, Helsinki Declaration and Russian laws.
Results: No one patient has dropped out of the study. In CLA group there were 6 mild and 2 moderate, in AMC group – 2 mild and 5 moderate adverse events that did not need to stop the treatment. Dyspnea (MRC scale), sputum volume and purulence significantly reduced in both groups after 12 months. FEV1 changes in both groups were unreliable. The number of exacerbations in CLA group reduced from 4.3±0.2 to 1.4±0.2, and in AMC group – from 4.5±0.3 to 2.4±0.3 per year. Exacerbation-free interval was longer in CLA group 258.4±17.0 days than in AMC group 192.8±24.8 (p<0.03).
Conclusion: long-term courses of clarithromycin for the COPD treatment are safe with few mild adverse events. Changes of dyspnea, spirometry parameters, sputum volume and purulence in CLA-treated and AMC-treated patients were equivalent. Long-term clarithromycin treatment of stage II COPD patients with frequent exacerbations was

associated with longer exacerbation-free interval compared to standard AMC treatment.

P849 **Empirical first-line antibiotic-therapy in adult patients with acute upper respiratory tract infections in eastern part of Poland**

L. Panasiuk, W. Lukas, J. Skorupka (Lublin, Zabrze, PL)

Objectives: The main objective of the study was the evaluation of the frequency and the verification of appropriateness of the use of antibiotics in empirical first-line therapy in adult patients with acute upper respiratory tract infections. In addition, the aim of the study was to discover whether there are any differences in the amount of antibiotics prescribed according to the place of residence (urban, rural), gender and age.
Methods: The analysis covered medical records of 4,047 patients from 47 health centres in the Lublin Region (eastern part of Poland) concerning the period of one year – 1 September 2005 – 31 August 2006. From among all the diagnoses, only newly diagnosed cases of acute upper respiratory tract infections were selected in patients who had no medical history of chronic respiratory diseases. Age, gender, and place of residence of patients were recorded, as well as the fact of prescribing or not prescribing an antibiotic by a physician during the first visit, and the type of antibiotic used.
Results: The documentation contained the records concerning 1,386 visits, the reason for which was qualified by physicians as acute infection of the upper respiratory tract. Acute pharyngitis and tonsillitis, acute respiratory tract infections of multiple and unspecified sites, a common cold, and acute bronchitis were the most frequent diagnoses made. While analysing all the cases it was noted that antibiotics were applied in empirical first-line therapy in 1,103 cases, which constituted 79.58% of the total number of morbid cases. The antibiotics most frequently used were: amoxicillin (26.77%), amoxicillin with clavulanic acid (13.1%), macrolides (12.5%), and doxycycline (10.5%). No statistically significant differences in the use of antibiotics were observed according to patients' age, gender, and place of residence.
Conclusions: The analysis showed that in the great majority of cases the use of antibiotics was inappropriate. If this situation persists, in the near future it will lead to an increase in the phenomenon of antibioticoresistance in Poland. In order to prevent this situation, it is necessary to carry out an extensive educational action concerning the hazardous effect of excessive use of antibiotics, both among physicians and the whole society.

Methods for antibiotic susceptibility testing

P850 **Investigative use only test card using the VITEK 2 system as compared to broth microdilution**

R. Buckner, D. Fuller, T. Davis, K. Newcomer, S. Mirrett, L. Reller, E. Smith-Moland (Indianapolis, Durham, Omaha, US)

Objective: The purpose of this study was to demonstrate the effectiveness of antimicrobial susceptibility tests for Cefalexin (CN), Cefditoren (CDN), Cefsulodin (CFS), and Ceftobiprole (BPR) on the VITEK® 2 platform.
Methods: This multicentre trial tested Gram-negative isolates using an investigative use only (IUO) card (GN14) containing CN, CDN, CFS, and BRP. Challenge isolates (100), reproducibility isolates (best 10 strains), and quality control isolates (20 replicates of *Pseudomonas aeruginosa* ATCC 27853 and *Escherichia coli* ATCC 25922) were tested at each site by automatic and manual dilution using the GN14 IUO card. Clinical isolates were tested by automatic dilution at all sites. Broth microdilution (BMD) reference testing was performed on all reproducibility, challenge, quality control and clinical isolates using the same standard inoculums prepared for the GN14 test cards. Reproducibility tests were performed in triplicate daily for three days. Essential agreement (EA) (within ± one log dilution) and categorical agreement (CA) (S/I/R) was determined for each microorganism/antimicrobial combination.
Results: Essential agreement for all 431 clinical isolates was > 93.0%, while categorical agreement was > 90.3% (Table 1). Reproducibility for the automatic diluted isolates was 100.0%, 98.9%, 97.8% and 98.9% for CN, CDN, CFS and BRP, respectively. For the manual dilution, reproducibility was 98.9%, 98.9%, 92.2% and 98.9% for CN, CDN, CFS and BRP, respectively. The EA, for 100 challenge experiments using automatic and manual dilution methods, was >96.0% for all antibiotics.

Table 1: Percent EA and CA for GN14 Card vs. BMD

Type of isolates		CN	CDN	CFS	BRP
Clinical (N = 431)	EA	93.0	97.7	96.8	97.2
	CA	96.3	90.3	95.8	95.4
Challenge Automatic Dilution (N = 100)	EA	100.0	99.0	97.0	100.0
	CA	99.0	93.0	95.0	93.0
Clinical & Challenge Auto Dilution (N = 531)	EA	94.4	97.9	96.8	97.7
	CA	96.8	90.8	95.7	94.9
Challenge Manual Dilution (N = 100)	EA	99.0	99.0	96.0	100.0
	CA	99.0	91.0	94.0	93.0

Conclusions: This evaluation provides convincing evidence that the performance of antimicrobial susceptibility tests for CN, CDN, CFS and BRP on the VITEK® 2 platform is comparable to conventional testing in a clinical laboratory.

P851 **Comparison of the VITEK®2 AST-N054 test card with MASTDISCS® manual disc testing for the detection of extended spectrum β-lactamase production in *Escherichia coli* with CTX-M phenotypes**

H. Donaldson, M. McCalmont, D.M. Livermore, P. Rooney, G. Ong, E. McHenry, R. Campbell, R. McMullan (Belfast, London, UK)

Objectives: A new antibiotic susceptibility card, AST N-054, was introduced for testing aerobic Gram-negative bacilli on VITEK®2 (bioMerieux) systems in 2007 and has been widely adopted for routine use in the UK. We compared its performance to an established manual method for detecting extended-spectrum β-lactamase (ESBL)-production in *Escherichia coli*. *E. coli* with CTX-M enzymes are now prevalent throughout the UK, partly owing to the spread of epidemic clones with CTX-M-15 enzyme.
Methods: ESBL-producing faecal isolates of *E. coli* (n = 337) recovered from patients in nursing homes were evaluated. Based on greater resistance to cefotaxime than ceftazidime in agar dilution, all were inferred to have CTX-M type enzymes. Seventy-three belonged to strain A, the most prevalent epidemic lineage, which typically produces a low level of CTX-M-15 enzyme; 64 were non-strain A and their CTX-M enzymes remain to be fully identified. Each isolate was tested using the AST N-054 card on the VITEK®2 and with MASTDISCS® ID ESBL detection disc diffusion (DD) tests (Mast Diagnostics). All VITEK®2 advanced expert system (AES) summary interpretations that included 'ESBL' were categorised as successful. The susceptibility result recommended by the AES software was also recorded.
Results: Overall, the AST N-054 card detected ESBL production in 93 of the 137 isolates tested (test sensitivity 67.9% [95% CI, 59.7–75.1]). Strain A accounted for the majority of the 44 detection failures, with 35/73 strain A isolates incorrectly reported vs 9/64 non-strain A isolates ($p<0.0001$). By comparison, manual detection based on UK national recommendations with screening using cefotaxime and ceftazidime discs followed by confirmation using the MASTDISCS® method correctly detected ESBL in 135 of the 137 isolates (test sensitivity 98.5% [95% CI, 94.5–99.9]). Of the 44 isolates found to be negative for ESBL production by VITEK®2, the AES reported 29 as susceptible to cefotaxime, and all as susceptible to ceftazidime and aztreonam.
Conclusion: These data suggest that the AST N-054 card for the VITEK®2 system may be less reliable than combination discs for

detection of CTX-M β-lactamase-producing *E. coli* circulating in the UK; particularly for the strain A isolates, which tend to be less resistant to cefotaxime and ceftazidime than most others. In consequence many ESBL producers may be inappropriately reported as susceptible to substrate cephalosporins.

P852 Analysis of the Dade Behring MicroScan Walkaway system for the identification and antimicrobial susceptibility testing of cystic fibrosis *Pseudomonas aeruginosa*

C.J. Megson, R. Townsend (Sheffield, UK)

Objectives: Cystic Fibrosis patients are often colonised with atypical, hypermutatable strains of *Pseudomonas aeruginosa* (CF-PSA). The ability of CF-PSA to mutate frequently promotes diversification within the CF lung resulting in multiple colonial morphotypes and conferring adaptive mutations such as loss of certain phenotypic characteristics and resistance to antimicrobials. Consequently it is unsurprising that CF-PSA are notoriously difficult both to identify and to assess for their antimicrobial susceptibility.
This evaluation assessed the ability of the Dade-Behring Walkaway system to correctly identify and accurately assess antimicrobial susceptibility of CF-PSA isolates by comparison with BSAC disc diffusion methodology.
Methods: 58 CF-PSA isolates of mixed morphotype inocula were used. These were tested using the Miscroscan NC-32 panel. Discrepancies in identification were further investigated using API 20NE. Five antimicrobial agents were compared with results interpreted using BSAC breakpoint guidelines.
Results: 66% of isolates identified correctly with a high probability (>85% likelihood). 15% identified correctly at low probability, the remainder (19%) either gave an incorrect identification with a low probability or failed to give an identification.
A total of 290 antimicrobial agent/isolate combinations were tested of which 240 (83%) were in complete agreement. The overall false resistant (major) error rate was 17% (50/290). No false susceptible (very major) errors were observed.
Conclusion: CF-PSA showed atypical reactions for several identification tests; notably only 69% of all isolates were positive for citrate utilisation, and 66% were positive for tobramycin resistance. Five of the identification tests within the panel are tests for antimicrobial resistance. Given that the levels of resistance in CF-PSA are unusually high, it seems inappropriate for susceptibility to be used as a means to achieve identification of these organisms.
In our hands for our CF-PSA isolates the system demonstrated apparently high false resistant rates.
It was noted however that many of the isolates that were resistant to meropenem demonstrated inducible resistance to other β-lactams. It may be that the Walkaway was able to detect resistant mutants that could not be discerned using BSAC guided disc diffusion and this area may warrant further investigation.

P853 Comparison of three automated systems (BD Phoenix, MicroScan WalkAway and VITEK 2) for detecting imipenem resistance in *Acinetobacter baumannii*

C. Kulah, E. Aktas, F. Comert, N. Ozlu, I. Akyar, H. Ankarali (Zonguldak, Istanbul, TR)

Objectives: Carbapenems are considered the gold standard treatment for multidrug resistant *Acinetobacter baumannii* infections, however, resistance to this agent has been reported increasingly. Reliable susceptibility testing results remains a critical issue for the clinical outcome for these patients. Automated systems are currently used in many clinical laboratories. This study was organised to evaluate the accuracies of three automated susceptibility testing methods for testing *Acinetobacter baumannii* against imipenem.
Methods: One hundred twelve selected isolates of *Acinetobacter baumannii* collected between January 2003 and December 2006 were tested to confirm imipenem susceptibility results. Bacterial isolates were identified according to conventional bacteriological techniques and confirmed by API 20 NE (bioMerieux, France). Strains were tested against imipenem by broth dilution, disk difusion, Etest (AB Biodisk, Sweden), BD Phoenix (Becton Dickinson), MicroScan WalkAway (Dade Behring) and VITEK 2 (bioMérieux) automated systems. Data were analysed by comparing the results from each test method to those produced by the reference broth microdilution (BMD) test performed using in-house prepared panels.
Results: MicroScan performed true identification of all *A. baumannii* strains while VITEK 2 unidentified one strain, and Phoenix unidentified two strains and misidentified two strains. The BMD testing showed that 25 strains were susceptible to imipenem while 87 were resistant All other test systems in the study produced errors when *A. baumannii* was tested against imipenem. Etest showed the best performance with only two minor error (1.8%). VITEK 2 produced eight minor errors(7.2%). BD Phoenix produced three major errors(2.8%). Disk diffusion produced two very major errors (1.8%) and three major errors (2.7%). MicroScan showed the worst performance in susceptibility testing with 28 very major errors (25%) and 50 minor errors (44.6%).
Conclusions: Testing difficulties for imipenem do exist in susceptibility testing systems. Reporting errors can have serious implications for the clinical outcome for patients. We suggest clinical laboratories using automated systems for routine use should consider using a second, independent antimicrobial susceptibility testing method to validate imipenem susceptibility.

P854 Evaluation of the BD Phoenix™ Automated Microbiology System to detect inducible-macrolide-lincosamide-streptogramin B resistance in *Staphylococcus* species

C. Gosnell, C. Yu, D. Turner, J. Reuben (Sparks, US)

Objectives: Macrolide-resistant (Mac-R) staphylococci may have constitutive or inducible resistance to clindamycin. Currently, constitutive resistance to clindamycin can be easily detected by a number of manual and automatic antimicrobial susceptibility testing methods. On the other hand, inducible resistance to clindamycin can only be detected by the D-test as described by CLSI. The D-test requires placing a 2-ug clindamycin disk and 15-ug erythromycin disk approximately 15 mm apart per standard disk diffusion testing methods. Mac-R staphylococci showing the “D-zone” would be reported as clindamycin-resistant. In this study, we will describe a new integrated test to be offered in the BD Phoenix Automated Microbiology System (BD Diagnostic Systems, Sparks MD) for the automatic detection of inducible clindamycin resistance in staphylococci.
Methods: A total of 408 strains of staphylococci, including 293 *Staphylococcus aureus* and 115 coagulase negative staphylococci were characterised by Standard Broth Microdilution (SBM). All Mac-R staphylococci strains were tested using the D-test. Each Mac-R staphylococci strain was then tested in the Phoenix system using panels with the integrated iMLSb test reagent and algorithm. Workflow and results obtained from the Phoenix method were compared to the CLSI method for accuracy.
Results: Out of the 408 strains tested, 194 strains were determined by SBM as Mac-R and clindamycin susceptible staphylococci. Of these strains, 136 were determined to be inducible-clindamycin resistant by the D-test. The following table compares the Phoenix vs. D-test results. The overall sensitivity and specificity using the Phoenix iMLSb test was 99.3% and 96.6%, respectively.

		D-Test	
		positive	negative
Phoenix iMLSb	positive	135	2
	negative	1	56

Conclusions: The integrated iMLSb test in the Phoenix System provides accurate detection of inducible-clindamycin resistance in staphylococci. This method also eliminates the necessity of performing the D-test and the associated subjective interpretation of test results.

P855 Identification and susceptibility testing of *Enterococcus casseliflavus* and *Enterococcus gallinarum* by Phoenix 100 system (Becton Dickinson)

K.-S. Chatzigeorgiou, A. Tarpatzi, N. Siafakas, M. Pantelaki, N. Charalampaki, L. Zerva (Chaidari, Athens, GR)

Objectives: Although *E. casseliflavus/flavescens* and *E. gallinarum* are of low pathogenic potential, they may be implicated in invasive infections. The aim of the present study was to assess their correct recognition by Phoenix and to investigate their antimicrobial susceptibility profile using the same system.
Methods: A total of 82 consecutive non-*E. faecalis* and non-*E. faecium* enterococcal isolates were collected during two hospital surveillance studies for VRE faecal carriage; all were identified as *E. casseliflavus/gallinarum* by Phoenix (without species discrimination). Speciation was confirmed by a multiplex PCR assay (specific for ddl-*E. faecium*, ddl-*E. faecalis*, vanA, vanB, vanC1/2, vanD, vanE and vanG genes). Pigment production was also recorded. Susceptibilities towards 8 antimicrobials (penicillin, ampicillin, erythromycin, gentamicin, streptomycin, linezolid, teicoplanin and vancomycin) were determined by Phoenix and E-tests (AB, Biodisk) against linezolid and teicoplanin were performed for selected isolates.
Results: According to PCR all 82 isolates harboured the vanC ligase gene and by pigment production 66 were identified as *E. gallinarum* and 16 as *E. casseliflavus/flavescens*. All but one isolates tested susceptible to both penicillin and ampicillin. Eleven strains (13.4%) were found to be intermediately resistant and 5 (6.1%) resistant to erythromycin. Five isolates (6.1%) exhibited resistance against streptomycin. For 3 *E. gallinarum* isolates Phoenix produced a teicoplanin MIC >16 μg/ml, not confirmed by the E-test and PCR (3 major errors, 3.6%). Vancomycin MICs by Phoenix ranged from 4 to >16 μg/ml. Regarding linezolid, Phoenix characterised 6 strains as resistant (all susceptible by E-test; at least 6 major errors) and 21 strains as intermediately resistant (only 4 intermediately resistant by E-test; at least 17 minor errors). On repeat testing Phoenix classified again 8 susceptible isolates as intermediately resistant and 1 intermediately resistant strain as susceptible (at least 9 minor errors).
Conclusion: *E. gallinarum* and *E. casseliflavus/flavescens* are accurately identified as a group by Phoenix and are rather multi-susceptible species with the former being more frequently recovered from faecal samples of hospitalised patients. Rare major errors with teicoplanin and major and minor errors with linezolid, which may call into question correct speciation, stress the need for confirmation with supplementary testing.

P856 Evaluation of the Oxoid M.I.C.Evaluator susceptibility test strip in comparison to Etest assay and BSAC agar dilution

S. Mushtaq, M. Warner, D.M. Livermore (London, UK)

Objectives: The Oxoid M.I.C.Evaluator™ strip comprises an antibiotic gradient immobilised on a plastic support strip. We compared its performance with AB Biodisk's Etest® product and with the BSAC agar dilution method, which was taken as a reference.
Methods and Materials: All tests, whether by M.I.C.Evaluator strip, Etest strip, or agar dilution were done on IsoSensitest agar, supplemented as recommended for agar dilution by the British Society for Antimicrobial Chemotherapy. The inocula used for both strip types corresponded to a 0.5 McFarland. A total of 8775 individual organism/antibiotic combinations were tested by each method; the total number of isolates was 837, chosen to represent most clinically relevant fastidious and non-fastidious species.
Results: Essential agreement of MIC values, ± 1 doubling dilution to the agar dilution reference method, with off-scale results excluded, was 88.2% for the M.I.C.Evaluator strip against 86.0% for the Etest strip. When one of more value was off-scale, (e.g. strip >32 mg/L and agar dilution 128 mg/L) agreement was 72.4% for the M.I.C.Evaluator strip against 69.9% for the Etest strip; this included instances, (e.g. cefotaxime and oxacillin vs. MRSA) where MICs are notoriously fickle. For both strip types, agreement was best for non-fastidious genera including staphylococci, enterococci, Enterobacteriaceae and non-fermenters and weaker for beta-haemolytic streptococci and *H. influenzae*. In many instances where there was disagreement with the reference method, the results of the M.I.C.Evaluator and Etest strips agreed with each other, whether for individual isolates, or for particular antibiotics against the generality of a species: for example, both tended to estimate lower imipenem MICs than agar dilution for *P. mirabilis*.
Conclusion: The M.I.C.Evaluator™ strip has essentially equivalent performance to the Etest® strip, with both giving good agreement to agar dilution results determined by the BSAC method.

P857 Performance evaluation of M.I.C.Evaluator™ strip (Oxoid) and comparison with the BSAC reference method

R.W. Smyth, S. Bengtsson, J. Cloke, G. Kahlmeter (Växjö, SE; Basingstoke, UK)

Objectives: To evaluate the performance of a new product, the M.I.C.Evaluator™ strip for the determination of minimum inhibitory concentrations (MIC) of antibiotics for a selection of reference strains, recent isolates and stored strains displaying a variety of resistance mechanisms.
Methods: The M.I.C.Evaluator™ strip was tested in parallel with the BSAC agar dilution reference method. Enterobacteriaceae, *Pseudomonas*, *Acinetobacter*, staphylococci, streptococci, enterococci, *Haemophilus* and *Neisseria* together with appropriate reference strains were tested. Antibiotics were as shown in the results table. Iso-Sensitest Agar with or without supplements was the basic medium. Inocula were standardised to 0.5 MacFarland, strips were placed on 90 mm dishes and incubated at a temperature of 35–37°C for 18–20 h or, for some strains, up to 24 h. The reference method was carried out according to BSAC guidelines. Results were read and recorded by different workers working independently.
Results: For each organism group/antibiotic combination the middle figure shows the essential agreement (EA) i.e. ± one dilution step, between results obtained with M.I.C.Evaluator™ strip and the reference method. The figure to the left shows the percentage yielding results two or more dilution steps lower than the reference method and the figure to the right shows the percentage of results two or more dilution steps greater than the reference method. All ATCC reference strains gave MIC results within the published range.

Antibiotic n =	Enterobacteriaceae 202	*Pseudomonas* 66	*Acinetobacter* 34	*Haemophilus* 53	*Staphylococcus* 153	*Streptococcus* 163	*Neisseria* 55	*Enterococcus* 102
Amoxy/clav	0–100–0			2–98–0				
Amoxycillin	0–84–16			4–96–0		1–97–2		
Ampicillin	0–95–5			0–96–4		1–99–0	9–89–2	0–85–15
Cefotaxime low	0–87–13			0–81–19		1–63–36	0–84–16	
Cefotaxime high	0–77–23			0–79–21		0–61–39	0–91–9	
Ciprofloxacin	0–70–30	0–97–3	0–97–3		0–92–8	0–100–0	0–76–24	
Erythromycin				0–100–0	0–93–7	4–93–3		
Gentamicin low	0–93–7	0–64–36	0–100–0			0–95–5		
Gentamicin high	0–95–5	0–73–27	0–91–9			1–92–7		
Imipenem	0–97–3	0–100–0	0–100–0	13–87–0		5–91–4		0–100–0
Linezolid					0–99–1	20–80–0		3–97–0
Levofloxacin	0–96–3			0–100–0	0–86–14	1–98–1		
Oxacillin					1–85–14	5–87–8		
Penicillin low					3–46–51	1–73–26	0–95–5	
Penicillin high					3–58–39	1–74–25	0–95–5	
Tetracycline				6–94–0	1–92–7	12–88–0	13–87–0	
Vancomycin						3–96–1		

Conclusion: M.I.C.Evaluator™ strip compared to BSAC reference method showed >80% EA for ampicillin, amoxicillin, amoxicillin/clavulanic acid, erythromycin, imipenem, levofloxacin and vancomycin. In almost all instances of poor agreement the M.I.C.Evaluator™ gave a result greater than that of the reference method.

P858 Comparison of Oxoid M.I.C.Evaluator™ device with broth micro-dilution and Etest® device from AB Biodisk for antimicrobial susceptibility testing of staphylococci, streptococci and enterococci

R. Rennie, L. Turnbull, C. Brosnikoff (Edmonton, CA)

Objective: The current study was designed to evaluate a new product utilising an agar based gradient endpoint system (MICE™) produced by Oxoid (Thermo Fisher Scientific) as an alternative to broth microdilution for accurate MIC test results of staphylococci, streptococci and enterococci that can be utilised effectively in critical care.
Methods: A total of 154 strains of MSSA, MRSA and CNS, 158 strains of *S. pneumoniae*, beta-haemolytic streptococci and *viridans* group streptococci, and 106 strains of enterococci were tested. A total of 13 antimicrobial agents that were evaluable for each genus and species were tested. The strains were inoculated into BMD trays (CLSI M7-A7) and onto Mueller Hinton agar. The MIC strips were added to the plates according to each manufacturer's instructions and were incubated for 20–24 hr at 35°C. Inhibition was read where the elliptical zone intersected with the strips. ATCC *S. aureus* 29213, *S. pneumoniae* 49619, and *E. faecalis* 29212 were the quality control strains.
Results: Quality control strains were within CLSI published ranges. For the clinical strains, 5300 agent-organism MIC results were available for analysis. Over 99% of results were within 2 doubling dilutions comparing BMD to either Oxoid's MICE™ or AB Biodisk's Etest® device. Compared to BMD there were 5 Very Major errors (0.09%), and 8 Major errors (0.15%) observed with both devices. Four of the 8 major errors occurred with penicillin and staphylococci
Conclusions: MICE™ device results for clinical strains of staphylococci, streptococci and enterococci were comparable to the gold-standard CLSI BMD observations and to Etest® device results for 13 evaluable antimicrobial agents. Additional antimicrobials are undergoing evaluation. The gradient endpoint MIC device provides accurate susceptibility test results for these Gram-positive clinical species.

P859 Comparison of Oxoid M.I.C.Evaluator™ device with broth micro-dilution and Etest® device from AB Biodisk for antimicrobial susceptibility testing of Enterobacteriaceae

R. Rennie, L. Turnbull, C. Brosnikoff (Edmonton, CA)

Objective: The current study was designed to evaluate a new product utilising an agar based gradient endpoint system (MICE™) produced by Oxoid (Thermo Fisher Scientific) as an alternative to manual and automated broth microdilution systems for accurate MIC test results of Enterobacteriaceae that can be utilised effectively in critical care.
Methods: 250 recent clinical strains of Enterobacteriaceae, including 16 genera and over 30 species were tested. Initially, seven evaluable antimicrobials were tested: ciprofloxacin, amoxicillin, amoxicillin-clavulanate, ampicillin, levofloxacin; and cefotaxime and gentamicin (low and high concentrations). The strains were inoculated into BMD trays (CLSI M7-A7) and onto Mueller Hinton agar. The MIC strips were added to the plates according to each manufacturer's instructions and were incubated for 20–24 hr at 35°C. Inhibition was read where the elliptical zone intersected with the strips. ATCC *E. coli* 25922 *P. aeruginosa* 27853, *S. aureus* 29213 and *E. faecalis* 29212 were the quality control strains.
Results: Quality control stains were within CLSI published ranges. For the clinical strains, 2250 agent-organism MIC results were available for analysis. Over 98% of results were within 2 doubling dilutions comparing BMD to either Oxoid's MICE™ or AB Biodisk's Etest® device. Compared to BMD there were 8 Very Major errors (0.4%), 1 Major error (0.04%) and 7 minor errors (0.3%) observed with both devices. Six of the 8 VM errors occurred with amoxicillin and ampicillin with *Proteus* species.
Conclusions: MICE™ device results for clinical strains of Enterobacteriaceae were comparable to the gold-standard CLSI BMD observations and to Etest® device results for seven evaluable antimicrobial agents. Additional antimicrobials are undergoing evaluation. The gradient endpoint MIC device provides accurate susceptibility test results for Enterobacteriaceae.

P860 Validation of M.I.C. Evaluator strips following ISO guidelines

M.H. Nabuurs-Franssen, M.T.H. Bohne, J.W. Mouton (Nijmegen, NL)

Objectives: Oxoid has developed a new system for determining the MIC. These M.I.C.Evaluator strips (M.I.C.E.) provide a gradient of antibiotic stabilised on a polymer strip covering 15 doubling dilutions.
The aim of the study was to evaluate these M.I.C.E. vs the MIC reference method (ISO 20776–1) according to ISO guidelines (ISO 20776–2).
Methods: Following the ISO protocol, during daily clinical laboratory work 300 consecutive Gram-negative strains (fresh isolates) were collected. Identification was performed following standard procedures. From each strain, the MICs were determined following ISO guidelines (ISO 20776–1) and instructions of the M.I.C.E. manufacturer, respectively. For the M.I.C.E. an inoculum of 0.5 McFarland was streaked on a Mueller-Hinton agar plate. The M.I.C.E. were put on the plate and incubated for 16–20 h. The MIC values were read following instruction by two independent lab technicians. The following M.I.C.E. were evaluated: gentamicin 256–0.016 mg/L (Ge256), gentamicin 1024–0.064 mg/L (GE1024), amoxicillin 256–0.016 mg/L (AM), cefotaxime 32–0.002 mg/L (Cef32), cefotaxime 256–0.016 mg/L (Cef256), levofloxacin 32–0.002 mg/L (LE), imipenem 32–0.002 mg/L (IM), ciprofloxacin 32–0.002 mg/L (CI). For the interpretation of the MIC and M.I.C.E. the EUCAST breakpoints were used. Discrepancy analysis was performed following the ISO guideline.
Results: The isolates collected belonged to the following species *Citrobacter* spp. (n = 35), *Enterobacter* spp. (n = 35), *Escherichia coli* (n = 30), *Hafnia alvei* (n = 3), *Klebsiella* spp. (n = 34), *Morganella morganii* (n = 30), Pantoea agglomerans (n = 3), *Proteus* spp. (n = 37), *Providencia rettgeri* (n = 3), *Serratia marcescens* (n = 3). 63% of the strains were susceptible for the different antimicrobial agents. The category agreement after discrepancy analysis was: Ge256 99%, GE1024 99%, AM 96%, Cef32 99%, Cef256 99%, LE 98%, IM 99% and CI 98%. Very Major Discrepancy was found only for CI 1%, Cef32 0.7% and Cef256 0.3%; and none for the other antimicrobial agents. There was no Major Discrepancy was for any antimicrobial agents.
Conclusion: The new M.I.C.E. to determine MICs demonstrated an excellent performance for the interpretive category determinations of SIR of the antimicrobial agents tested. M.I.C.E. provide a welcome new methode to determine susceptibility during routine practice.

P861 Effect of lower inoculum on MIC broth microdilution: a comparison with the ISO reference method

M.H. Nabuurs-Franssen, M.T.H. Bohne, J.W. Mouton (Nijmegen, NL)

Objectives: Rapid, accurate and reproducible determination of the MIC value is important for adequate patient care, for local and international resistance surveillance. For epidemiological studies of susceptibility and for comparison of new and existing antimicrobial agents. The ISO reference method (ISO 20776–1) prescribes an inoculum of $2–8\times10^5$. The rationale behind the lower limit is not fully clear. In addition, some MIC devices do use lower inocula. For instance, the (former) guideline of the BSAC stated 10^5 /ml. The aim of this study was to evaluate the effect of a lower inoculum size on the MIC determination using the ISO protocol (ISO 20776–2).
Method: During daily clinical laboratory work 300 consecutive Gram-negative strains (fresh isolates) were collected. Identification was performed following standard procedures. From each strain, the MICs

were determined with both the 2–8×10^5 inoculum (ISO 20776–1) and with a 5–10×10^4 inoculum. MIC values were read independently by two lab technicians. For the interpretation of the MICs the EUCAST breakpoints were used. The following antimicrobial agents were tested: amoxicillin (AM), cefotaxime (Cef), ciprofloxacin (CI), amoxicillin/clavulanic acid (AC). The MIC values of the lower inoculum size was compared to the reference method following ISO guideline (ISO 20776–2).

Results: The isolates collected belonged to the following species *Citrobacter* spp. (n = 35), *Enterobacter* spp. (n = 35), *Escherichia coli* (n = 30), *Hafnia alvei* (n = 3), *Klebsiella* spp. (n = 34), *Morganella morganii* (n = 30), Pantoea agglomerans (n = 3), *Proteus* spp. (n = 37), *Providencia rettgeri* (n = 3), *Serratia marcescens* (n = 3). Forty-five percent of the strains were susceptible for the different antimicrobial agents. Following ISO guidelines the essential agreement after discrepancy analysis was: AM 99%, Cef 98%, CI 98%, AC 98% and the category agreement was: AM 96%, Cef 99%, CI 97.%, AC 92%, respectively. The Very Major Discrepancy was found only for Cef 0.3%. Discrepancy analyses with the M.I.C.E. found the same MIC as the 5–10×10^4 inoculum. A Major discrepancy was only found for Cef 0.3%. Minor discrepancies were found for AM 4%, Cef 0.6%, CI 3.3%, AC 8.3%.

Conclusion: In this study, a lower inoculum size (5–10^4) did not influence the outcome of the MIC determination; there was a very good category agreement and essential agreement between the different inoculum sises for the antimicrobial agents tested compared to the reference method.

P862 Detection of VISA/hVISA in routine clinical isolates: Microscan® modified procedure vs. Etest®

M. Ballardini, M. Meledandri, A. Ferrari, S. Falco, M. Balice, M. Gallo, C. Fontana, P. Bernaschi, M. Carletti, A. Silvestri, N. Corradetti, G.P. Testore (Rome, IT)

Objectives: Detection of VISA/hVISA strains should be pursued in routine clinical microbiology, to prevent possible therapeutic failure. Although PAP-AUC is known as reference method, many laboratories use more manageable techniques, primarily Etest® (AB-Biodisk). In this work we evaluate the performance of MicroScan® (Dade-Behring) automated method (also with a modified procedure) vs. Etest.

Methods: MRSA clinical isolates, mostly from SSI, BSI and ulcers of hospitalised patients in Italy (8 centres in Rome) in 2007, not classified by respective centres as VISA/hVISA (vancomycin MIC ⩽2 μg/ml at Vitek® or Phoenix® ASTs for all strains), were retested as follows: culturing on VA agar screen (vancomycin 6 μg/ml – Biolife - 0.5 and 2 McF, 48 h); vancomycin's MIC measure for screened colonies by means of Etest 'standard' (MHA 0.5 McF, 48 h), Etest 'macro method' (BHI 2 McF, 48 h) and Microscan panels (standard 0.5 and modified 2 McF inocula, 48 h).

Results: After screening, 106 collected strains produced 53 suspected 'not-VSSA' (none detected by respective Vitek/Phoenix ASTs). With CLSI 2006 breakpoints, Microscan showed high sensitivity (100%; Wilson CI 75–99), low specificity (55%; CI 38–71), high npv (100%; CI 87–99) and low ppv (47%; CI 29–65) vs. Etest (standard inoculum 0.5 McF, both with Etest and Microscan). Using Walsh's (2001) classification, we obtained similar results: sens.100% (CI 60–99), spec.27% (CI 15–42), npv100% (CI 89–99), and ppv19% (CI 10–35): in this case, 2 McF inoculum was used both for 'macromethod' and Microscan. Correlation (Spearman) was also observed between Microscan and Etest MICs/results: R=0.650 ($p<0.001$) and R=0.512 ($p<0.001$), respectively for 0.5 and 2 McF.

Conclusion: Microscan seemed to be an alternative to Etest for detection of presumptive VISA/hVISA, even when instrument is forced to work likewise an Etest macromethod. High sensitivity, with advantage of automation, allows practical first level identification of strains. On the other hand, overall data show that use of a glycopeptide agar (VA or TP) for screening is essential for recovery of suspected strains, especially in hospital settings as those analysed, with probable significant unrecognised rate of VISA/hVISA.

P863 Mecillinam susceptibility in *Escherichia coli* with and without ESBL: a comparison of disk diffusion and Etest on Mueller-Hinton agar and Iso-Sensitest agar

E. Matuschek, C.G. Giske, G. Kahlmeter (Växjö, Solna, SE)

Objective: Mecillinam is a 6-amidinopenicillin highly active against Gram-negative bacteria such as *Escherichia coli* and *Klebsiella pneumoniae* and has been used successfully in Scandinavia for the treatment of uncomplicated urinary tract infections. Mecillinam is semi-stable to many β-lactamases but MIC values for β-lactamase producing strains are elevated to varying degrees. Currently used MIC breakpoints for mecillinam and *E. coli* in Europe are 8/8 (BSAC), 2/8 (CA-SFM), 2/8 (NWGA) and 1/8 (SRGA). This study compared susceptibility results with Etest and disk diffusion on Mueller-Hinton agar (MHA) and Iso-Sensitest Agar (ISA) in *E. coli* strains with and without β-lactamases, including a variety of ESBLs.

Methods: Mecillinam Etest (AB Biodisk, Solna, Sweden) and disks (10 μg, Oxoid, Basingstoke, UK) were used on ISA (Oxoid) and MHA (Oxoid). All testing was performed with Kirby-Bauer inoculum, except for disk diffusion on ISA which was done with a semi-confluent inoculum (as described in the methods by BSAC and SRGA). A total of 280 *E. coli* isolates from urine samples were investigated. Of these, 161 were consecutive strains from Kronoberg County and 119 were ESBL-producers from Karolinska University Hospital. ESBL production was detected by clavulanate synergy disks (Oxoid), followed by PCR targeting CTX-M, TEM and SHV β-lactamases, and subsequent sequencing.

Results: There was excellent correlation between susceptibility testing performed on ISA and MHA, with r>0.99 for MIC v MIC both for the consecutive *E. coli* and the ESBLs. The zone diameters were generally smaller on MHA, but again correlation was strong (r=0.93 for the consecutive *E. coli* and r=0.97 for the ESBLs). The distribution of mecillinam MIC from our consecutive *E. coli* was closely similar to that presented on the EUCAST website with a peak at 0.125 mg/L. The ESBL-producing *E. coli*, mostly CTX-M-15 and -14, had higher MIC values with a peak at 0.5–2 mg/L. EUCAST has suggested a preliminary MIC breakpoint of S ⩽ 8, R>8 mg/L. Our results indicate a tentative disk diffusion breakpoint for a mecillinam 10 μg disk of S ⩾15 mm, R ⩽14 mm, both for MHA and ISA.

Conclusion: There was good agreement between MIC and disk diffusion for mecillinam and *E. coli* on both ISA and MHA. We suggest that disk diffusion can be used to predict mecillinam susceptibility for *E. coli* strains both with and without ESBL enzymes.

P864 Comparison of Etest and combined disk for detection of metallo-β-lactamase-producing isolates

E. Campana, R. Picão, A. Nicoletti, R. Girardello, S. Andrade, A.C. Gales (São Paulo, BR)

Objective: The aim of this study was to comparatively evaluate the ability of E-test MBL strip (AB BIODISK, Solna, Sweden) and combined disk (CD) assay for detection of MBL-producing *Pseudomonas aeruginosa* (PSA), *Acinetobacter* spp. (ACB) and enterobacterial clinical isolates.

Methods: A total of 46 genetically unrelated clinical isolates were tested, including 28 *P. aeruginosa* (10 SPM-1, 14 IMP-type, 3 VIM-type and 1 GIM-1), 1 P. putida (IMP-1), 10 *Acinetobacter* spp. (9 IMP-1, 1 SIM-1), and 7 enterobacterial strains [*Enterobacter cloacae* (1 IMP-1 and 3 VIM-1), *Klebsiella pneumoniae* (2 IMP-1) and *Serratia marcescens* (1 IMP-1)]. Nineteen imipenem (IMI)-resistant isolates but non-MBL producers were included as negative controls. The isolates were classified as MBL producers by E-test according to the manufacturer's instructions. The CD assay was performed adding 2, 4, 6, 8 and 10 ul of EDTA (100 mM) to IMI disks. The isolates were categorised as MBL producers considering an increase of ⩾5 mm in inhibition zone of IMI/EDTA disks, compared to the IMI disk alone.

Results: The sensitivity (S) and specificity (E) of E-test and CD assay are shown in the table below. Results of S and E (100% and 33.3%, respectively) for E-test were the same regardless of the MBL type produced. The best E results obtained by Etest and CD were observed for the Enterobacteriaceae group (80% and 100%, respectively). Two positive controls (*Acinetobacter* spp.) and four negative controls (2 *P. aeruginosa* and 2 enterobacterial strains) were categorised as non determinable (ND) by E-test. The best S and E results for CD assay were achieved after dropping 6 ul of the EDTA.

	E-test®		CD	
Species	S %	E %	S %	E %
General	100	33.3	76	95
Acinetobacter spp.	100	0	40	50
P. aeruginosa	100	25	93	83
Enterobacteriaceae	100	80	100	100

S: sensitivity; E: specificity.

Conclusions: Our results indicated that, although the E-test was able to correctly identify almost all MBL-producing isolates, false positive MBL results may occur when using this methology. On the other hand, false negative results may arise when CD test is used to screen for MBL-producing isolates. In summary, these two methods are suitable for preliminary MBL screening for some selected species, but should not be used as the unique indicator of such resistance determinants production.

P865 Comparison of Neo-Sensitabs™ with paper discs in the routine disc diffusion antimicrobial susceptibility testing

J.H. Kauppila, V.M. Koskela, M. Koskela (Oulu, FI)

Objectives: The aim of this study was to compare the use of Neo-Sensitabs™ (Rosco, Taastrup, Denmark) with paper discs for antimicrobial susceptibility testing by disc diffusion method according to the recommendations of CLSI.

Methods: We analysed antimicrobial susceptibility of 476 clinical bacterial isolates and 7 ATCC control strains by parallel disc diffusion susceptibility testing with paper discs (Oxoid Ltd, UK) and Neo-Sensitabs™ (table 1). Clinical strains were tested once, but testing was repeated when interpretative disagreement was found. ATCC control strains were tested weekly 10 times.

Results: Zone correlation with the Pearson test value for diameters produced by the discs of two manufacturers was high. Overall agreements (test results within 4 mm range) were also very high. When the comparison was based on CLSI breakpoint categorisation, agreement ranged between 78.5% and 100% (table 1).

Very major, major and minor error rates were 0.2% (8 strains), 0.15% (6 strains) and 2.7% (106 strains) of all analyses, respectively. Three out of 8 very major errors occurred when there was no intermediate category. The rest 5 were detected when testing amoxicillin + clavulanic acid (AMC) or cefuroxime (1 case) activity against ESBL-strains. 59% of all errors occurred when testing activity of betalactams (mostly AMC) against ESBL-strains, and that is very understandable considering the character of this kind of betalactamase enzymes.

All MRSAs were found by both oxacillin discs and only 1 was missed by Oxoid cefoxitin disc, but the oxacillin inhibitory zones of the Neo-Sensitabs™ were more difficult to read at MRSA-strains. Oxoid vancomycin discs failed to detect 4 VRE-strains.

Other observations in routine use: Occasional blank paper discs were found (totally resistant at first and fully susceptible at re-testing). No Neo-Sensitabs™ found to be blank. Paper discs were dropped from the plate at about 1–2% of the analyses. The Neo-Sensitabs™ were not dropped. The Neo-Sensitabs™ were broke down at about 1–2% of the analyses, and it sometimes hampered the measurement of the zone sise. The dispenser of the Neo-Sesitabs™ has 7 locus, which makes the edge effect more prominent in some cases.

Conclusion: The zone diameters produced by Neo-Sensitabs™ and paper discs correlate well and showed good interpretative agreement. Therefore, the Neo-sensitabs™ are potential alternative to the paper discs for antimicrobial susceptibility testing by disc diffusion method.

Table 1: Correlations and agreements of the test results for clinical strains

		Agreement		No. of tests performed			
	Pearson correlation coefficient	Overall	based on CLSI breakpoint categorisation	STC	EC	PAE	AGNR
Ampicillin 10 ug	0.992	96.6	100.0		29		
Aztreonam 30 ug	0.980	97.9	93.6			10	37
Cefoxitin 30 ug	0.969	88.9	98.6	144			
Ceftazidime 30 ug	0.954	98.1	94.8			44	169
Ceftriaxone 30 ug	0.981	97.1	95.9				170

STC = *Staphylococcus* spp., including 34 MRSA strains. EC = *Enterococcus* sp., including 21 VRE strains. PAE = *Pseudomonas aeruginosa*. AGNR = Aerobe Gram-negative rod, including 41 ESBL strains.
1. 95% of disagreements were strains producing ESBL-, AmpC or K1-β-lactamases.
2. 7/8 of disagreements were VRE-strains. In 4 cases Oxoid discs failed to detect VRE. So the rates of true test results considering the resistance mechanism are 99.0% for Rosco tablets and 95.0% for Oxoid discs.

P866 Comparison of two methods (Etest and MicroScan) for detecting vancomycin susceptibility in *Staphylococcus aureus*

E. Cercenado, O. Cuevas, A. Vindel, M. Goyanes, M. Marin, E. Bouza (Madrid, ES)

Objective: The efficacy of vancomycin in the treatment of infections due to *Staphylococcus aureus* and specifically to MRSA has come under debate. There is also a concern for the decreasing in vitro susceptibility of isolates to vancomycin, the difficulty in laboratory detection, and the potential therapeutic implications of resistance. Moreover, vancomycin efficacy is lower against MRSA infections with agr group II isolates. In this study we compared two methods for detecting vancomycin susceptibility among clinical isolates of *S. aureus* and determine the agr groups of the MRSA isolates.

Methods: A total of 463 *S. aureus* isolates (135 MRSA) obtained from a national multicentre survey in Spain in a prevalence study performed in 2006 were evaluated. Vancomycin susceptibility was determined using the microdilution method MicroScan (Dade-Behring) and the Etest method (AB Biodisk). The same inoculum was used for both methods. Detection of heterorresistance (GISA/hGISA) was determined by the Etest macrodilution method. A multiplex PCR was used to determine the agr types of the MRSA isolates.

Results: The origins of the isolates were skin/wound (67%), respiratory (13%), blood (8%), urine (6%), and others (6%). A total of 449 *S. aureus* isolates (97%) had vancomycin MICs of less or =1 mg/L, and 14 (3%) had MICs of 2 mg/L with MicroScan. By Etest, 2 isolates had vancomycin MICs of 0.75 mg/L; 58 of 1 mg/L; 242 of 1.5 mg/L; and 161 of 2 mg/L. None of the isolates was GISA/hGISA. Among the MRSA, 129 isolates (95.5%) had vancomycin MICs of less or =1 mg/L, and 6 (4.5%) had MICs of 2 mg/L with MicroScan. By Etest, 1 isolate had a vancomycin MIC of 0.75 mg/L; 3 of 1 mg/L; 67 of 1.5 mg/L; and 58 (43%) of 2 mg/L. Among the MRSA isolates that had a MicroScan result of less or = 1 mg/L, 3% of isolates had both MicroScan and Etest of less or =1 mg/L, 51% had an Etest of 1.5 mg/L, and 46% of 2 mg/L. Of the 6 remaining isolates with MicroScan MIC of 2 mg/L, 2 isolates had an Etest result of 1.5 mg/L, and 4 isolates of 2 mg/L. The agr groups of the MRSA isolates with vancomycin MICs of less or =1 mg/L by MicroScan

were: 17% group I, 80% group II, and 3% group III. All isolates with vancomycin MICs of 2 mg/L by MicroScan were agr group II.
Conclusions: The results of this study show variability in methods for the determination of the in vitro susceptibility of *S. aureus* and MRSA isolates to vancomycin and a high proportion of MRSA isolates belonging to the agr group II.

P867 Re-evaluation by microdilution of Etest method to determine tigecycline susceptibility in *Acinetobacter*

M. Casal, F. Rodríguez, J. Blanco, E. Garduño, R. Ortiz de Lejarazu, A. Tenorio, R. Bartolomé, N. Larrosa, B. Johnson, N. García-Escribano (Córdoba, Badajoz, Valladolid, Barcelona, ES; Schaumburg, US; Madrid, ES)

Objectives: There has been different communications related to not reliability of E-test method with different microorganisms. The aim of this study is to reevaluate by microdilution the presumably resistance to tigecycline (TGC) of 95 Spanish *Acinetobacter* isolates.
Methods: All isolates were derived from different sources. We have collected *Acinetobacter* isolates with a MIC >2 μg/ml, obtained by E-test, from four Spanish hospitals during 6 months. Organism collection, transport and retest of TGC susceptibility was carried out by Laboratories International for Microbiology Studies, a division of International Health Management Associates, Inc. (Illinois. United States). Minimum inhibitory concentrations (MICs) were determined by the CLSI (2007) recommended broth microdilution testing method. TGC was supplied by Wyeth Pharma and all other antimicrobials were supplied by Microscan (Dade Behring, Sacramento, CA). CLSI breakpoints were used for all the antimicrobials. For TGC we used the breakpoints recommended by FDA and EUCAST for Enterobacteriaceae.
Results: Despite of the results obtained by E-test in which all the isolates were resistant to TGC, by microdilution all the isolates were susceptible. TGC was the most potent agent with a MIC50 of 0.5 μg/ml and a MIC90 of 1 μg/ml. One isolate out of 95 had a MIC of 4 μg/ml for TGC. Therefore according to EUCAST and FDA TGC breakpoints, resistance to TGC was 1.1% and 0% respectively. Percentages of resistance to other antimicrobials are shown in the next table.

Antibiotic	No. Resistant isolates	Resistance (%)
Piperacillin-tazobactam	87/95	91.6
Ceftazidime	88/95	92.6
Cefepime	89/95	93.7
Meropenem	86/95	90.5
Levofloxacin	85/95	89.5
Amikacin	69/95	72.6
Minocycline	4/95	4.2
Tigecycline		
EUCAST	1/95	1.1
FDA	0/95	0

Conclusions: TGC was the most active antimicrobial against *Acinetobacter*. It is important to take into account that E-test underestimates in vitro activity of TGC vs. *Acinetobacter*. This could have important implications for patients with an *Acinetobacter* infection.

P868 Vancomycin-resistant enterococci: validation of susceptibility testing and in vitro activity of novel antibiotics

M. Rathe, L. Kristensen, H. Schumacher (Herning, DK)

Objectives: Acquired vancomycin resistance among Danish clinical isolates is rare making detection of low level resistance challenging. We evaluated the current breakpoints, given by EUCAST, ability to discriminate vancomycin resistant enterococci (VRE) from vancomycin susceptible strains. Furthermore we evaluated the antimicrobial activity of daptomycin, linezolid and tigecycline towards both VRE and vancomycin susceptible strains.
Methods: A total of 125 unique isolates were tested. The isolates were classified by PCR as either vanA, vanB or susceptible. They were divided upon 82 *Enterococcus faecium* (33 vanA, 25 vanB and 24 susceptible) and 43 *Enterococcus faecalis* (1 vanA, 20 vanB and 22 susceptible). On each day of testing appropriate QC strains were tested. All determinations were within published QC ranges. MICs were determined with Etest (AB Biodisk) on MüllerHinton (MH) agar according to the instructions of the manufacturer. Disk diffusion test were performed using vancomycin (5 μg.), tigecycline (15 μg.) and linezolid (10 μg.) disks from Oxoid on Iso-sensitest agar, according to the recommendations of the Swedish Reference Group for Antibiotics.
Results: All strains were susceptible to tigecycline (MIC50 and MIC90 were 0.125 mg/L) and linezolid (MIC50 and MIC90 were 2 mg/L). For daptomycin MIC50 and MIC90 were 2 and 4 mg/L respectively. Disk diffusion results were in concordance with Etest results. Vancomycin MIC determination by Etest produced 4 very major errors (resistant strains misinterpreted as susceptible) when compared to the vancomycin genotype. Disk diffusion produced 17 very major errors for *E. faecalis* and 15 for *E. faecium*. A tentative breakpoint of 15 mm. for *E. faecalis* produced only three very major errors while a tentative breakpoint of 16 mm. for *E. faecium* produced only four very major errors. Off note we found that 96% of strains with the vanB gene and 20% of the susceptible strains had a diffuse inhibition zone edge.
Conclusion: Our study suggests that disk diffusion using the current breakpoints is inadequate when testing for vancomycin resistance, producing an unacceptably high number of very major errors. Modifying breakpoints would lessen the number of such errors considerably but not eliminate them. Inspecting the inhibition zone for a diffuse edge may contribute to identifying resistant strains.

P869 Evaluation of phenotypic methods for detection of extended-spectrum β-lactamases in a clinical microbiology laboratory

Y. Cosgun, M. Yucel, E. Yildiz, A.E. Karakoc (Ankara, TR)

Objective: Extended spectrum β-lactamases (ESBLs) are an increasing cause of resistance in nosocomial isolates of Enterobacteriaceae. The laboratory detection of ESBLs can be complex and sometimes misleading. The aim of this study is to evaluate the results of CLSI ESBL disk diffusion screening criteria in 243 *Escherichia coli* and 140 *Klebsiella* spp. nosocomial isolates, together with the results of CLSI disc diffusion clavulanic acid inhibition effect (CAIE), VITEK 2 CAIE and double disk synergy (DDS) methods.
Method: A total of 383 Gram-negative bacilli (243 *E. coli*, 120 *Klebsiella pneumoniae* and 20 *Klebsiella oxytoca*) which were isolated between April 2005-December 2006 and defined as nosocomial pathogens according to CDC criteriae were included in this study. All the strains were evaluated with respect to CLSI screening criteria using the discs; cefpodoxime (POD), ceftazidime (CAZ), cefotaxime (CTX), ceftriaxone (CRO) and aztreonam (ATM). Isolates that were considered to be potential ESBL producers according to the CLSI screening criteriae were then examined with CLSI disc diffusion CAIE using CAZ and CTX in the presence and absence of CA. All the strains were also analysed by VITEK 2 system (AST-GN13 panel, BioMerieux, France) according to MIC breakpoint values of CTX, CTX/CA, CAZ, CAZ/CA, cefepime (FEB), FEB/CA. DDS was tested evaluating the synergistic effect of amoxicilline clavulanic acid (AMC) with CAZ, CTX, CRO, POD and ATM.
Results: According to CLSI screening criteria 148 isolates (91 *E. coli*, 51 *K. pneumoniae*, 6 *K. oxytoca*) were determined as potential ESBL producers. Of these 148 isolates; 139 were DDS positive, 140 were VITEK 2 CAIE positive. Considering the CLSI ESBL confirmation criteria, 134 isolates showed CAIE using CAZ, CAZ/CA and 133 isolates showed CAIE using CTX, CTX/CA. The sensitivities of the five discs used for ESBL disk diffusion screening were as CRO > CTX = ATM > POD > CAZ in decreasing order.

Conclusion: Although phenotypic methods for determination of ESBL production have been widely used in routine microbiology laboratories, they have certain limitations. While the results in this study favour the use of either automated antimicrobial susceptibility system or DDS for this purpose, CLSI phenotypic confirmation with these methods increase the reliability.

P870 A practical aid for detection of extended-spectrum β-lactamases in Enterobacteriaceae

N. al Naiemi, Y.J. Debets-Ossenkopp, C. Vandenbroucke-Grauls, P.H.M. Savelkoul (Amsterdam, NL)

Objectives: The detection of Extended-Spectrum Beta-Lactamases (ESBLs) is of special importance, because this resistance genes present serious implications for therapy. Currently, genotypic characterisation of ESBL genes is considered the gold standard for ESBL identification. However, the detection of ESBL genes with PCR and sequencing is complex and does not provide information about their expression. In this study, we evaluated the performance of the combination of the molecular hyplex® ESBL ID (h-ES-ID) test and the ESBL screening agar (ESA) in the identification of ESBL-producing Enterobacteriaceae isolates.
Methods: The h-ES-ID is a multiplex-PCR-ELISA for the direct detection of β-lactamase-producing bacteria. In the presence of relevant DNA, specific amplification products of the blaTEM, bla SHV, bla CTX-M (except CTX-M-8) and bla OXA-1 group are synthesised and subsequently visualised with the h-ES-ID hybridisation modules. The ESA is a MacConkey agar with third generation cephalosporins, AmpC β-lactamase inhibitor and vancomycin. We examined a total of 149 clinical Enterobacteriaceae isolates, 61 of them had been previously characterised as ESBL-producers with PCR and sequencing. The other 88 isolates were ESBL negative.
Results: The sensitivity, specificity and duration of test of h-ES-ID and ESA were 98% (60/61), 57% (50/88), 3 hours, 100% (61/61), 93% (82/88) and 18 hours respectively. With the combination of h-ES-ID and ESA, all the ESBL-positive and ESBL-negative isolates were detected correctly. CTX-M ESBL producers were detected within 3 hours with h-ES-ID. The low specificity of h-ES-ID was mainly due to TEM-1 producers among *Escherichia coli* isolates. These isolates were correctly identified with the ESA.
Conclusion: The combination of h-ES-ID and ESA is a quick, effective, and easy to use method for ESBL detection, especially of CTX-M ESBLs, which are the most prevalent ESBLs worldwide. This combination of tests provides useful early therapeutic guidance by the rapid identification of ESBL-positive isolates.

P871 Extended-spectrum β-lactamases screening agar with AmpC inhibition

N. al Naiemi, J.L. Murk, P.H.M. Savelkoul, C.M. Vandenbroucke-Grauls, Y.J. Debets-Ossenkopp (Amsterdam, NL)

Objectives: The serious increase in the prevalence of Extended-Spectrum Beta-Lactamases (ESBLs) worldwide creates a need for effective screening methods to detect these resistance genes. The currently used screening agars have low specificity, mainly due to growth of isolates of species with inducible AmpC β-lactamases. In this study we evaluated an ESBL Screening Agar (ESA) which inhibits growth of AmpC-producing isolates and Enterococci, and compared it with the commercially available BLSE agar (AES Laboratory, France) for selective isolation and presumptive identification of ESBL-producing Enterobacteriaceae.
Methods: The ESA consists of two MacConkey Agars containing either ceftazidime 1.0 mg/l or cefotaxime 1.0 mg/l + cloxacilline 400 mg/l + vancomycine 64 mg/l. The BLSE agar is a commercial double-plate agar (MacConkey + ceftazidime 2 mg/l and Drigalski + cefotaxime 1.5 mg/l). The agars were evaluated with 208 Enterobacteriaceae isolates, 70 of them had been previously genotypically characterised as ESBL-producers. The other 138 isolates were ESBL negative. The ESA was further evaluated with 100 clinical specimens. All clinical specimens were futher characterised for ESBL production with ESBL combined disc test and ESBL Etest.
Results: The sensitivity and specificity of the ESA and the BLSE agar tested with the 208 Enterobacteriaceae isolates were 100% (70/70) and 84.7% (117/138), and 100% (70/70) and 57.2% (79/138) respectively. Isolates of species with inducible AmpC were most commonly the false positives on BLSE agar. The ESA detected all 5 ESBL-positive clinical specimens correctly, 4 specimens were false positive. The sensitivity and specificity of the ESA in the clinical specimens in this study were 100% and 95.7% respectively.
Conclusion: The specificity of ESA for screening of ESBL-producing strains was significantly better than the specificity of BLSE agar; the better performance of the ESA was mainly due to less false positive results due to Amp-C-producing strains. The ESA performed well also when inoculated directly with clinical specimens. We conclude that ESA is a sensitive and convenient method to directly screen for ESBL-producing organisms in clinical specimens.

P872 Detection of ESBLs in various *Enterobacter cloacae* isolates in the Polish External Assurance National Quality Control Scheme POLMICRO 2007

E. Stefaniuk, J. Fiett, J. Empel, M. Gniadkowski, E. Zurek, W. Hryniewicz, B. Chmylak (Warsaw, PL)

Objectives: The aim of this study was to evaluate quality of performance of microbiology diagnostic laboratories in Poland. POLMICRO is the National External Quality Assurance Scheme Programme in Poland. It addresses several important questions in bacterial identification and susceptibility testing. In one of 2007 editions *Enterobacter cloacae* was selected for distribution as a resistant alert pathogen.
Methods: Nine isolates of *E. cloacae* were prepared as a part of POLMICRO 2007/III. Each of 476 laboratories participating in the programme received a set of three phenotypically different isolates. The aim of every laboratory was to identify the strains to the species level, provide susceptibility testing results and to detect and interpret the AmpC- and/or ESBL-mediated resistance. The results were delivered via Internet. The study set of *E. cloacae* strains included: a) strains PM-107, PM-108 and PM-109 with AmpC derepression, b) strains PM-110, PM-111 and PM-112 with inducible AmpC and ESBL, and c) PM-115, PM-116, PM-117 with AmpC derepression and ESBL.
Results: Results were received from 467 (99.36%) laboratories and 434 laboratories obtained acceptable results. Because of the educational character of the control some kinds of errors were permitted. Four-hundred and sixty-four laboratories correctly identified isolates to the species level. Most of laboratories correctly determined susceptibility to given antibiotics and provided correct clinical interpretation. The minority of laboratories had difficulties with the proper interpretation of resistance mechanism. Some of these, 9.66% have misinterpreted the AmpC derepressed mutants as ESBL producers. Some others, 3.65% have not detected ESBLs in wild-type strains whereas 13.09% laboratories have not identified ESBLs in the context of the AmpC derepression.
Conclusions: The great majority of participating laboratories (93%) were able to properly detect β-lactamase mediated resistance mechanisms in *E. cloacae*. The results achieved by most laboratories in POLMICRO 2007/III indicated their competence in the area covered by the control.

P873 Rapid Etest MIC testing using CHROMagar and Mueller-Hinton agar for Gram-positive and Gram-negative aerobes

A. Engelhardt, A. Yusof, P. Ho, C. Johansson, K. Sjöström (Solna, SE)

Objectives: Same day MIC results of key antibiotics against important Gram+ and Gram− pathogens can be clinically valuable. Rapid results can be used to verify, correct, adjust or de-escalate empiric therapy, as necessary. Appropriate and adequate therapy implemented early can impact clinical outcome and save significant costs. We compared a

prototype CHROMagar (CMA) to Mueller Hinton agar (MHA) for MIC testing with Etest to evaluate the possibility of obtaining same day results for 12 antibiotics of choice for 14 clinically important species of aerobes.
Methods: 108 challenge strains, including MRSA, GISA/hGISA, VRE, ESBL, AmpC, MBL, OXA phenotypes used comprised: staphylococci (18), enterococci (11), *Escherichia coli* (17), *Klebsiella pneumoniae* (6), *Enterobacter cloacae* (5), *Citrobacter freundii* (5), *Serratia marcescens* (5), *Pseudomonas aeruginosa* (16), *Acinetobacter baumannii* (10), *Stenotrophomonas maltophilia* (10) and *Burkholderia cepacia* (5) and 9 ATCC reference strains. Etest strips (Gram+: oxacillin, vancomycin, linezolid, daptomycin, tigecycline, gentamicin, tetracycline, ciprofloxacin, rifampicin, clindamycin, erythromycin, trim/sulfa), (Gram-: ciprofloxacin, amikacin, tobramycin, gentamicin, aztreonam, piperacillin/tazobactam, cefepime, cefotaxime, imipenem, tigecycline, colistin, trim/sulfa) were tested on CMA and MHA according the manufacturer's instructions and read at 4, 6, and 24 h.
Results: Good MIC agreement between CMA and MHA (80–100% +/− 1 dilution) was seen at 24 h for 153/168 (91%) of drug/species combinations (>8000 data points). Enterobacteriaceae could be read at 6 h and results agreed (+/-1 dilution) with 24 h values for > 90% of cases for both media. 50% of Gram+ strains could be read at 6 h while Gram-negative non fermenters (GNF) and certain resistant phenotypes could only be read after overnight incubation. Colour changes on CMA were useful species markers.
Conclusion: Rapid same day Etest MIC results for key antibiotics could be reliably obtained for Enterobacteriaceae, and some staphylococci and enterococci with CMA and MHA. GNF and certain resistant phenotypes required overnight incubation. CMA should be further evaluated for specimen MIC testing to generate same day results for urgent clinical cases.

P874 Evaluation of a new Etest strip for detection of plasmidic AmpC

A. Engelhardt, A. Yusof, P. Ho, C. Johansson, K. Sjöström (Solna, SE)

Objectives: Simple and reliable methods for detection of plasmid mediated AmpC phenotypes are needed in clinical laboratories. In a previous study (ICAAC abstract D-0451, 2006), Etest prototype strips for detection of AmpC based on cefotetan (CN) ± cloxacillin (CLO) was found to be useful. However, cefotetan powder is no longer readily available. Cefoxitin (FX) resistance used as a screen for AmpC, comprise an alternative to CN for the design of a FX based test. This new FX±CLO prototype strip was compared to CN±CLO using genotypically characterised strains.
Methods: FX 512–8 ug/mL ±CLO double-sided Etest strip was tested with 48 clinical strains comprising: *Escherichia coli* (24), *Klebsiella pneumoniae* (7), *Proteus mirabilis* (1), *Serratia marcescens* (4), *Klebsiella oxytoca* (1), *Enterobacter aerogenes* (7), *Enterobacter cloacae* (2), *Morganella morganii* (2). AmpC genotypes (PCR based) included CMY-1, CMY-2, DHA-1, ACC, FOX and MIR. Standard Etest MIC procedure for Gram-negative aerobes was used and reduction of the cephamycin MIC by ⩾3 dilutions by CLO or the presence of a "phantom zone" or deformation of inhibition ellipses after 16–20 h incubation was interpreted AmpC positive.
Results: See table.

		Etest AmpC Results			
		CN±CLO		FX±CLO	
Phenotype	Strains (N)	+	−	+	−
Plasmidic AmpC	29	29	0	26	3
Chromosomal AmpC	15	13	2	10	5
Negative controls	4	0	4	0	4
	Detection of Plasmidic AmpC (%)				
	Sensitivity	100		90	
	Specificity	100		91	

Conclusion: Etest FX±CLO showed acceptable sensitivity (90%) and specificity (91%) for detection of various genotype plasmidic AmpC enzymes and may comprise an alternative diagnostic tool for routine use in clinical laboratories.

P875 Detection of plasmid mediated AmpC β-lactamase in clinical isolates by three different methods

S. Ak, B. Sener, G. Hascelik (Ankara, TR)

Objectives: AmpC mediated β-lactam resistance in *Escherichia coli* and *Klebsiella* spp. is an emerging problem all over the world. High level AmpC production is typically associated with in vitro resistance to all β-lactams except for carbapenems and cefepime. AmpC detection is important to ensure effective therapeutic intervention and optimal clinical outcome. Nevertheless, detection of AmpC mediated β-lactam resistance is a challenge for laboratories. There is no recommended CLSI guidelines for detection of this resistance mechanism. The aim of our study is to address this issue by tetsting different methods.
Methods: A total of 210 blood isolates of *E. coli* and *Klebsiella* spp. resistant to cefoxitin, amoxycillin-clavulanic acid, aztreonam, and any of cephalosporins were taken to the study. All isolates were identified by Phoenix automatised system. Susceptibility testing against imipenem, ceftazidime, cefotaxime, aztreonam, cefepim, cefotetan, cefpodoxime, cefoxitin, amikacin, tobramycin, amoxicillin-clavulanic acid and ciprofloxacin were done by disc diffusion. For the phenotypic detection of plasmid mediated AmpC β-lactamase inhibitor based method with boronic acid and modified-three dimensional test were used. The isolates found as AmpC β-lactamase positive based on phenotypic results, were confirmed by multiplex PCR for the presence of six different classes of AmpC β-lactamase coding genes.
Results: Boronic acid inhibition test revealed 46 positive isolates. When the inhibition test performed by boronic acid was coupled with clavulanic acid to rule out ESBL presence, the number of positive isolates decreased to 20. Modified-three dimensional test yielded 26 positive results. With multiplex PCR 4 isolates were confirmed as plasmid mediated AmpC β-lactamase producers. All of these four isolates had inducible type AmpC β-lactamase and none of them had ESBL.
Conclusion: Although boronic acid inhibition test can be useful for phenotypic detection of AmpC type β-lactamase, clavulanic acid must be added to the inhibition test in order to prevent the false positive results on account of presence of ESBL. For the confirmation of presence of AmpC β-lactamase, molecular methods, although expensive and labour intensive, should be used in clinical laboratories.

P876 Phenotypic AmpC detection – which inhibitor is best?

R. Hope, M. Warner, R. Hill, D.M. Livermore (London, UK)

Objectives: Synergy testing for conformation of AmpC activity is not so well established as for ESBLs, and the inference of AmpC phenotypes often relies on indirect indicators, e.g. resistance to cefotaxime and cefoxitin but not cefepime. Oxacillins and boronic acid derivatives, do however, inhibit AmpC enzymes and we compared their utility in synergy based detection tests for these enzymes.
Methods: The potential inhibitors, cloxacillin 100 mg/L, benzo(b)thiophene-2-boronic acid 100 mg/L and phenylboronic acid 200 mg/L were tested in combination with cefotaxime, ceftazidime, cefpirome and cefoxitin by the BSAC agar dilution method against 71 oxyimino-cephalosporin or carbapenem-resistant isolates with a variety of known resistance mechanisms.
Results: In general, cefotaxime was the best indicator substrate for AmpC hyperproduction in Enterobacteriaceae, irrespective of the inhibitor. Thus, with either boronic acid derivative ⩾8 fold synergy was seen with cefotaxime for >90% of AmpC hyperproducing Enterobacteriaceae, with fewer than 5% false positive results for strains with ESBLs or other resistance mechanisms. Cloxacillin gave ⩾4-fold synergy for ⩾90% of AmpC producing Enterobacteriaceae too but this low potentiation threshold was associated with poor specificity, with 30%

false positives among the isolates with other modes of cephalosporin resistance. Moreover cloxacillin failed to potentiate cephalosporin MICs for AmpC-hyperproducing *P. aeruginosa* isolates; whereas 16-fold, synergy typically was seen for the boronic acid, ceftazidime combinations. Some failures (mostly with *Enterobacter*) occurred when ESBLs were present together with AmpC enzymes.
Conclusion: Benzo(b)thiophene-2-boronic acid/cefotaxime combinations provided the most effective AmpC synergy test for Enterobacteriaceae, with cefotaxime MICs potentiated ⩾8 fold for >90% of the AmpC producers and with good specificity. Boronic acid/ceftazidime combinations were more suitable for *P. aeruginosa*.

P877 Evaluation of Sensititre® Yeastone® for direct antifungal susceptibility testing from blood cultures

A. Camporese, S. Grosso, G. Bruschetta, R. De Rosa, M. Avolio (Pordenone, IT)

Objectives: The aim of this study was to evaluate Sensititre YeastOne (TREK Diagnostic Systems, Cleveland, USA), already used in our routine diagnostics for performing in-vitro antifungal susceptibility testing, starting directly from the bottle of blood culture positive for yeasts, with the explicit aim of intervening to reduce the TAT for antifungal susceptibility testing.

Organisms (no. tested) and antifungal agents	MIC (ug/ml)					
	Range		MIC_{50}		MIC_{90}	
	Reference procedure	Direct procedure	Reference procedure	Direct procedure	Reference procedure	Direct procedure
Candida albicans (20)						
amphotericin	0.008–0.06	0.008–0.06	0.03	0.03	0.06	0.06

Methods: In our laboratory, blood culture bottles are normally incubated using the system BacT/ALERT 3D (bioMerieux, Marcy l'Etoile, France). Sensititre YeastOne was used by direct inoculation from positive blood culture bottles in 40 cases of candidaemia. All the results obtained directly from a positive bottle were compared with those obtained using standard laboratory procedures, after sub-culturing from a positive bottle onto solid media. The strain of *Candida parapsilosis* ATCC 22019 was used for quality control. The direct susceptibility test was performed as follows: the positive blood culture bottle was shaken and used to prepare a Gram stain to confirm the presence of yeast monomicrobism. Five to six ml of the sample were aspirated with a vacutainer test tube (Sarstedt, Nümbrecht, Germany) and centrifuged at 3200 revs for 15 minutes; the microbial pellet was gradually suspended in a small aliquot of physiological solution then diluted with physiological solution in order to obtain turbidity of 0.5 McFarland. This final suspension was used to perform the susceptibility test according to the manufacturer's instructions. Incubation at 35°C was continued for 24 hours.
Results: The table summarises the in vitro susceptibilities (MIC's range, MIC 50 and MIC 90) of the 40 isolates of *Candida* spp., compared with the results obtained in accordance with the standard procedures. Considered as a whole, out of a total of 40 strains tested, no very major errors or major errors were revealed and only five minor errors (98% agreement rate out of a total of 240 drug/bug combinations tested).
Conclusion: The results obtained from direct inoculation of Sensititre YeastOne demonstrated excellent performance and compared very well with tests performed using standard procedures. In addition, results were easy to interpret and available on average 3 days earlier than conventional results, allowing a potentially very significant reduction in the TAT and providing tangible information, about the current management of antifungal therapy or, if necessary, its modification.

P878 Detection and reporting betalactam resistance phenotypes in *Escherichia coli* and *Klebsiella pneumoniae*: a multicentre proficiency study in Spanish laboratories

M.C. Conejo, C. Mata, F. Navarro, Á. Pascual and the GEMARA collaborative group

Objective: To evaluate the ability of Spanish microbiology laboratories in detecting and reporting betalactam resistance phenotypes in well-characterised clinical isolates of *Escherichia coli* and *Klebsiella pneumoniae* expressing extended-spectrum β-lactamases (ESBL) or AmpC β-lactamases.
Methods: Twelve well-characterised strains were sent to 57 laboratories: 6 clinical isolates expressing the most prevalent ESBL in our country (2 CTX-M-10, 1 CTX-M-9, 1 CTX-M-14, 1 TEM-4 and 1 SHV-12), 3 isolates producing AmpC-type enzymes [ACBL; 2 plasmid-mediated (FOX-5 and CMY-2) and one *E. coli* hyperproducing chromosomal ACBL], and 3 ATCC reference strains (1 with SHV-8). Laboratories were requested to use routine methods for identification and antimicrobial susceptibility testing (AST), considering the strains as blood isolates. Reference results were established by two independent laboratories by using API strips for identification and CLSI microdilution and disc diffusion methods and interpretative criteria for AST.
Results: Automated systems were used by 61% of laboratories for bacterial identification and AST. The remaining laboratories used semi-automated or manual systems. Ninety one percent of laboratories correctly recognised all seven ESBL producers and consequently low rates of errors were observed when testing cephalosporins and aztreonam. The highest rates of errors with all the ESBL producers were observed when testing the penicillin/β-lactamase inhibitor combinations, but in more than 60% of cases these errors were not related to the MIC value but to the microbiologist interpretation (minor errors). No discrepancies were observed for carbapenems in ESBL producers. Correct recognition of all three ACBL producers was assessed by 47% laboratories. ACBL producers were erroneously reported as ESBL producers in 11 cases and as penicillinase hyperproducers associated or not to permeability reduction in 10 cases. Interpretative criteria applied to ACBL phenotype were not uniform, but a tendency of considering carbapenems as the only therapeutic option was observed.
Conclusions: Most laboratories in Spain detected the ESBL phenotype, but detection of the ACBL phenotype by routine methods needs to be improved.

P879 Assessment of capacity of Russian microbiological laboratories to detect ESBL production in Gram-negative bacteria by phenotypic methods

O. Kretchikova, N. Ivanchik, R. Kozlov (Smolensk, RU)

Backgound: Patients with infections caused by ESBL-producing organisms are at an increased risk of treatment failure with β-lactam antibiotics. Thus ability of microbiological laboratory to detect ESBLs is very important. No adequate information of ability of Russian microbiological laboratories to detect ESBL is available so far.
Objectives: To assess capability of microbiological laboratories in different regions of Russia to detect ESBL production in Gram-negative bacteria with phenotypic methods.
Methods: This study was a part of nationwide external quality control program. Forty three microbiological laboratories from 22 regions of Russia participated in the study. Two "blinded" strains (ESBL-producing strains of *Enterobacter cloacae* and *Providencia rettgeri*) were distributed for identification, susceptibility testing to cefotaxime (CTX), ceftazidime (CAZ), cefepime (CFP) and interpreting resistance phenotypes (including ESBL) with any test routinely used in the laboratory. E.cloaceae was producing TEM-29 (ESBL). *P. rettgeri* was producing TEM-1 and STX-M-3 (ESBL). MICs of both strains for different antimicrobials are presented in the Table. Sises of zones of inhibition for CTX, CAZ and CFP formally were in “susceptible” range for both strains according to CLSI breakpoints.
Results: In 3 of 43 laboratories automatic susceptibility testing systems (ATB Expression and VITEK) were used, in remaining 40 laboratories susceptibility testing has been performed by disk diffusion method. In all laboratories identification was done correctly. ESBL production in E.cloaceae was detected only in 4 (9.3%) laboratories and the strain was considered as resistant to CTX, CAZ and CFP. None of these laboratories used automatic susceptibility testing systems (ASTS). In all laboratories using ASTS E.cloaceae strain has been reported as susceptible to CTX, CAZ and CFP. ESBL production in *P. rettgeri* was detected in 7 (16.3%) laboratories, 3 of which used ASTS and the strain was considered as resistant to CTX, CAZ and CFP.

Table: MICs of tested strains for antimicrobials (mg/L)

Strain	CTX	CTX/CL	CAZ	CAZ/CL	CFP	CFX	AMX	AMX/CL
E. cloacae	0.25	0.25	8	0.25	1	64	256	64
P. rettgeri	8	0.125	0.5	0.25	8	2	256	256

CTX = cefotaxime, CAZ = ceftazidime, CFP = cefepime, CFX = cefoxitine, CL = clavulanic acid, AMX = amoxicillin.

Conclusion: Capacity of routine clinical microbiological laboratories in Russia to detect ESBL production in Gram-negative bacteria is inadequate and needs to be improved.

β-lactamases: laboratory detection

P880 Validation of the extended-spectrum β-lactamase phenotype with molecular methods

T. Bruderer, L. Poirel, H. Adler, P. Nordmann, R. Frei (Basel, CH; Le Kremlin-Bicetre, FR)

Objectives: In order to validate extended-spectrum β-lactamase (ESBL) screening and confirmation assays, we determined the presence of 6 different ESBL-encoding genes in a representative collection of Swiss isolates showing an ESBL phenotype. In the subset of isolates in which no ESBL genes were detected, the presence of SHV-1 hyperproducing penicillinase, group D oxacillinases, and plasmid-mediated AmpC β-lactamases was additionally assessed.
Methods: The clinical Enterobacteriaceae isolates expressing an ESBL phenotype were consecutively collected at the University Hospital Basel (n = 39) or obtained from several Swiss laboratories (n = 33). As phenotypic confirmatory test, three different ESBL Etest strips (AB Biodisk, Sweden) were used: ceftazidime, cefotaxime, and cefepime, each plus/minus clavulanic acid. Repetitive patient isolates and K1 hyperproducing *Klebsiella oxytoca* were excluded. To determine the molecular types, PCR amplifying SHV, TEM, CTX-M, VEB, PER, GES, OXA-1, OXA-10 genes as well as genes of the SHV-1 promoter region and of 6 different phylogenetic groups of AmpC was performed and amplicons were sequenced.
Results: Among 162 isolates showing an ESBL phenotype, molecular analysis demonstrated that 103 (63.6%) expressed a CTX-M type, 23 (14.2%) a SHV ESBL-type, 17 (10.5%) a TEM ESBL type, one GES-1, and one PER-1 ESBL. Among the 21 (13.0%) isolates in which no ESBL-genes could be detected, 12 *Klebsiella pneumoniae* and 6 *Escherichia coli* harboured the typical C to A mutation in the second position of the SHV-1 –10 promoter region associated with hyperproduction of SHV-1. These 18 isolates showed a characteristic susceptibility and ESBL screening/confirmation pattern that differed significantly from all molecularly confirmed ESBL isolates except for GES-1. The remaining two *E. coli* and one *Citrobacter koseri/ amalonaticus* contained an OXA-1 gene explaining the false positive cefepime/cefepime + clavulanic acid Etest.
Conclusions: Almost all phenotypic ESBL isolates in which no ESBL genes could be detected were SHV-1 hyperproducers known leading to false positive results in phenotypic ESBL tests. The relatively high number of false positive results might be explained by the low incidence of ESBLs in Switzerland. Because of their unique characteristics determined in this study, SHV-1 hyperproducers can be excluded.

P881 Detection of ESBL production by the Hyplex® ESBL ID multiplex PCR-ELISA system

O. Paniara, E. Kraniotaki, E. Belesiotou, E. Perivolioti, M. Nepka, K. Fountoulis, E. Platsouka (Athens, GR)

Objectives: Extended-spectrum β-lactamases (ESBL), the enzymes that are able to hydrolyse diverse β-lactam antibiotics, are widely distributed among Enterobacteriaceae. This study was performed in order to compare a novel multiplex-PCR-ELISA-System with the conventional microbiological methods for the detection of ESBL-producing blood isolates of *Klebsiella pneumoniae*, in a Greek tertiary hospital.
Methods: Sixty-two different *K. pneumoniae* isolates from blood cultures of inpatients (77% ICU, 18% medical wards, 5% surgical wards) were collected over a two year period. Two *Escherichia coli* blood isolates one positive and the other negative for ESBL production, were used as positive and negative controls respectively. They were identified by standard methods and MICs were determined by the VITEK 2 automated system, according to CLSI guidelines. ESBL production was screened by Etest ESBL. The Hyplex® ESBL ID method involves amplification of blaTEM, blaSHV, blaCTX-M and blaOXA bacterial DNA by multiplex PCR and hybridisation of the PCR products to specific oligonucleotide probes: a Consensus probe (TEM, SHV, CTX-M and OXA specific) and a CTX-M specific probe. Nine of the above positive blood cultures were tested directly with the Hyplex® ESBL ID test.
Results: Sixty-one out of sixty-two *K. pneumoniae* blood isolates were found to produce an ESBL activity by the Etest. The same isolates gave a positive result with the Consensus probes demonstrating the presence of ESBL phenotype-associated genes (sensitivity 100%, specificity 100%). Only three of the sixty-one isolates gave an additional positive result with the CTX-specific probes proving ESBL production. The nine blood cultures that were tested directly gave identical results with their respective isolates.
Conclusion: The hyplex®ESBL ID test can be reliably applied for the detection of ESBL genes carriage by Gram-negative species directly in positive blood cultures or in blood isolates. This diagnostic utility may be very useful for the timely detection of ESBL genes and has to be evaluated.

P882 ChromID ESBL agar for the detection of extended-spectrum β-lactamase producing Enterobacteriaceae

J. Montgomery, J. Wang, J. Nakos, V. Gurtler (Melbourne, AU)

Objectives: Extended spectrum β-lactamases (ESBL) are major nosocomial pathogens, and more recently have emerged in community patients. This study evaluated chromID ESBL (chromID) chromogenic agar for the rapid detection of ESBL in Enterobacteria as part of the routine identification and susceptibility testing of isolates, and was compared with molecular detection.
Method: Using a multipoint inoculator (in-house agar dilution method) 244 pure cultures of Enterobacteria was stamped onto chromID agar, as part of the daily identification procedure. In addition Jarlier's double disk synergy tests were also performed. PCR for CTX-M, SHV and TEM genes was performed on all isolates. AmpC PCR was also done.
Results: Of 244 isolates, 97 were ESBL positive by PCR. These were *Citrobacter freundii* (6), *Enterobacter aerogenes* (5), *Enterobacter cloacae* (30), *Escherichia coli* (30), *Klebsiella oxytoca* (10), *Klebsiella pneumoniae* (13), *Proteus penneri* (1) and *Proteus vulgaris* (2). Enzymes detected included TEM (45), SHV (42) and CTX-M (65). Multiple genes were detected in 51 (53%) of isolates. Five PCR positive isolates that failed to grow on chromID, were *K. pneumoniae* (CTX-M, TEM and SHV), *K. oxytoca* (CTX-M), *E. aerogenes* (SHV) and two *E. coli* one with SHV and the other TEM. There were 36 that grew on chromID but were not confirmed by PCR. Of these false positives 27 (75%) were chromosomal or plasmid-mediated AmpC producers. Of 30 Enterobacteria that grew on chromID but produced no pigment, 13 were ESBL producers and included *C. freundii* (3), *E. coli* (6), *K. oxytoca* (1), *E. cloacae* (2) and *P. vulgaris* (1). The sensitivity and specificity of chromID was 95% and 80%.In comparison Jarlier's disk synergy testing were positive in 64 isolates of which 58 were ESBL producers. This method did not detect 39 of the ESBL producers. Sensitivity was 60% and specificity of 96%.
Conclusions: ChromID agar is a very sensitive medium for the detection of ESBL-producing Enterobacteria. Some isolates that grow on the medium but have no pigmentation are ESBL producers. AmpC producing Enterobacteria are a significant source of false positive growth.

P883 Comparison of phenotypic tests for detection of plasmid-mediated AmpC β-lactamases

J. Montgomery, J. Nakos, V. Gurtler (Melbourne, AU)

Objectives: Detection of plasmid-mediated AmpC β-lactamases is important for optimal outcome in patients with serious infections. Laboratory detection of these enzymes is difficult. This study compared six phenotypic methods of detection of plasmid-mediated AmpC β-lactamases with PCR.
Methods: Organisms selected included 106 *Escherichia coli*, 17 *Klebsiella* spp., three *Proteus mirabilis* and two *Salmonella* spp. Etest MICs wre performed on all isolates. Multiplex PCR comprised MOX, CMY, DHA, ACC, EBC and FOX genes. Phenotypic tests; cefoxitin resistance (CR): disk testing with benzeneboronic acid (BB), benzothiopene-2-boronic acid (BT) and 3-aminophenyl boronic acid (AB) each combined with a third generation cephalosporin with and without the boronic acid derivative, (a zone diameter difference of five millimetres or more indicated enzyme presence): tris-EDTA (TE) and cefoxitin with a flattening of the zone indicating inhibition; Cica-beta-C-test (CC) using the chromogenic cephalosporin HMRZ-86, combined with a boronic acid inhibitor. Disk diffusion tests used standard CLSI methods. Etest MIC were performed according to the manufacturers instructions and interpreted according to CLSI criteria.
Results: Of a total of 128 isolates studied 29 were PCR positive. Twenty-one of 106 *Escherichia coli*; five of 15 *Klebsiella pneumoniae*, one of two *Klebsiella oxytoca* and two *Salmonella* spp. were PCR positive. Enzymes detected were DHA (13) and CIT (16). Three *Proteus mirabilis* were PCR negative. Six PCR positive and 57 PCR negative isolates had cefoxitin Etest MIC results equal to or less than 16 mg/L. The table summaries the results when compared with AmpC detection by PCR.

Phenotypic method	Sensitivity %	Specificity %	Positive Predictive Value	Negative Predictive Value
CR	76	58	34	89
BB	76	80	52	92
BT	72	61	35	88
AB	69	88	63	91
TE	45	92	62	85
CC	31	91	53	82

Conclusions: No one phenotypic method tested reliably detected all plasmid-mediated AmpC enzymes. A combination of CR and CC may be useful but requires further study. Screening methods still require PCR confirmation.

P884 Development and validation of a novel media (CHROMagar ECC CTX-M) for isolation of CTX-M producing Enterobacteriacae whilst inhibiting ampC producing organisms

L.P. Randall, A. Brook, M. Kirchner, C. Teale, N. Coldham, M. Woodward, E. Liebana, F. Clifton-Hadley (New Haw, UK; Parma, IT)

Objectives: To develop and validate a novel media based on CHROMagar ECC to isolate bacteria containing the blaCTX-M gene whilst inhibiting ampC strains and to evaluate different phenotypic tests for identifying blaCTX-M strains as being ESBL producers.
Methods: A panel of strains was assembled to assess different agars for ability to isolate bacteria containing the blaCTX-M gene whilst inhibiting ampC strains. The panel comprised 123 isolates (mainly *E. coli*) and was characterised genotypically (tested for blaCTX-M blaOXA, blaSHV, blaTEM and ampC genes) and phenotypically (cefepime, cefotaxime, cefpodoxime and ceftazidime MAST EsbL ID disks, the Cica-Beta test and MICs). The final evaluation panel comprised ~ 54% and ~ 32% of strains positive for blaCTX-M and ampC genes respectively. A range of agents was evaluated as additives to CHROMagar ECC and the most optimal combination selected to produce CHROMagar ECC CTX-M. The CHROMagar ECC CTX-M was assessed against other agars with and without enrichment for the isolation of blaCTX-M positive organism from bovine faeces spiked with 10^1 to 10^4 cfu/g of blaCTX-M strains with and without the presence of ampC strains.

Table 1: Recovery of CTX-M positive colonies from bovine faecal samples spiked with ~10^1 to 10^4 cfu/g CTX-M positive strains with and without ~10^4 cfu/g ampC positive strains

Agar	% of colonies that were CTX-M positive for spike levels; **With/without presence of ampC strains**			
Spike level	**10^1**	**10^2**	**10^3**	**10^4**
CA-ECC	0/0	17/0	0/0	20/17
CA-ECC + 2 μg/ml CTX	0/80	0/17	50/100	50/100
CA-ECC + 8 μg/ml CTX	17/100	0/100	17/100	50/100
bioMérieux ESBL	0/67	0/50	33/83	83/100
CA-EEC-CTX-M	**67/83**	**67/100**	**67/100**	**67/100**

CA-ECC, CHROMagar ECC; CA-EEC-CTX-M, CHROMagar ECC CTX-M, CTX, cefotaxime. If no colonies were recovered from faeces directly cultured onto agars, then enrichment was used (faeces overnight in buffered peptone water at 37º).

Results: CHROMagar ECC CTX-M showed a 98.5% sensitivity and 83.6% specificity for growth of the blaCTX-M positive strains in the panel and this was superior to CHROMagar ECC with addition of different concentrations of either cefotaxime or ceftazidime and to bioMérieux ESBL-Bx agar. CHROMagar ECC CTX-M was also overall superior to other agars for the isolation of blaCTX-M strains from bovine

faeces, and was capable at detecting ~ 10 cfu blaCTX-M strains per gram of faeces, even in the presence of ampC strains (Table 1). The sensitivity and specificity of MAST ESbL ID disks for confirming the blaCTX-M strains as ESBL strains ranged from 93.9% to 100% for the each set of disks but the sensitivity and specificity could be increased to 98.5% and 100% respectively by taking results from two sets of disks. The Cica-Beta test showed a 77.3% and 90.9% sensitivity and specificity for confirming the blaCTX-M strains as ESBL strains.
Conclusion: The results show that CHROMagar ECC CTX-M is a highly sensitive, selective and specific agar for isolating medically important blaCTX-M strains, particularly in the presence of ampC strains. The MAST ESbL ID disks proved to be highly sensitive and specific at confirming blaCTX-M strains as ESBL's, particularly if results were taken from two sets of disks.

P885 Evaluation of a chromogenic medium (chromID™ ESBL, BioMérieux) for the screening of ESBL-producing *Escherichia coli*

T. Halaby, W. Goessens, T. Krooshof, A. Hofkamp, M.G.R. Hendrix (Enschede, NL)

Introduction: Detection of Extended-Spectrum-Beta-Lactamase (ESBL) producing *E. coli* isolates relies on decreased susceptibility for at least one of the indicator antibiotics as recommend by the CLSI. The results are subsequently confirmed in an ESBL confirmation test. This two-step procedure is necessary to increase the specificity as decreased susceptibility may rely on mechanisms other than ESBL. Since ESBLs are increasing worldwide companies have developed selective chromogenic media in which the most important ESBL-producing organisms are identified by a difference in colony colours. Growth followed by colourisation is only possible if organisms possess β-lactamases capable of hydrolyzing the indicator antibiotics present in the agar.
Objectives: to evaluate the performance of a chromogenic medium (chromID tm ESBL, BioMérieux) compared to the CLSI ESBL-screening procedure.
Methods: 1968 *E. coli* strains prospectively sampled between 1/9/2006 and 1/9/2007 isolated from community and hospitalised patients were included. Susceptibility testing is performed by agar dilution and ESBL detection is performed using ceftazidime, ceftriaxone and aztreonam as indicator antibiotics. *E. coli* strains with MICs > 1 mg/l for either agent are subjected for confirmation. Confirmation for ESBL is performed by combined double disks (DD) of Becton Dickinson (Sparks, MD, USA), consisiting of cefotaxime (30 micg) or ceftazidime (30 micg) alone and combined with clavulanic acid (10 micg). All isolates growing on the chromID tm ESBL with pink to burgundy colours were also subjected to the same confirmation procedure.
Results: 1799 isolates were ESBL negative according to the CLSI guidelines and did not grow on ChromID tm ESBL plates. 169 isolates were tested positive of which 81 also grew on ChromID tm ESBL plates. 75 out of the 81 were confirmed ESBL-positive by DD. 64 isolates out of 88 not growing on ChromID tm ESBL but positive in the CLSI screening were negative in the DD confirmation. One isolate missed by ChromID tm was tested positive in the DD confirmation. 23 remaining isolates were not tested.

	ChromID ESBL pos	ChromID ESBL neg	
CLSI pos	81	88	169
CLSI neg	0	1799	1799
			1968

Conclusion: Application of the CLSI guidelines resulted in twice as much isolates suspected for ESBL as by ChromID tm ESBL-agar plates. However, the majority of the extra positives are false positive probably due to the presence of other resistance mechanisms. Screening for ESBL with ChromID tm ESBL-agar plates has a higher specificity than the method advocated by CLSI.

P886 Evaluation of a chromogenic agar plate as screening medium for the detection of extended-spectrum β-lactamase-producing Enterobacteriaceae

M. Boudewijns, M. Zuliani, M. Vandermarliere, J. Colaert (Kortrijk, BE)

Objectives: To evaluate the performance of a selective chromogenic agar medium (ChromID ESBL, bioMérieux) as primary medium for the detection of extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae directly from clinical specimens.
Methods: Clinical specimens (urine samples, lower respiratory tract samples, perineal swabs and wound swabs) were prospectively collected from a hospitalised patient population. Specimens were inoculated on the ESBL medium and the in house media (MacConkey agar medium and blood agar medium). Isolates were identified to the species level by use of VITEK 2 ID cards (bioMérieux). Isolates were screened for ESBL production by MIC analysis and the ESBL test with VITEK 2 AST-N045 cards (bioMérieux). ESBL production was confirmed by use of the combined-disk method (ceftazidime and cefepime with and without clavulanic acid, Rosco) and the E-test method (cefotaxime, ceftazidime and cefepime with and without clavulanic acid, AB Biodisk).
Results: A total of 558 specimens were obtained from 374 patients. The ESBL medium yielded growth of 111 isolates from 101 specimens (18%). These 101 isolates consisted of 57 Enterobacteriaceae isolates (51%). The non-Enterobacteriaceae isolates belonged mainly to the species *Pseudomonas aeruginosa*. Of the 57 Enterobacteriaceae isolates, 30 isolates were confirmed as being ESBL producers (specificity 27%). The non-ESBL-producing Enterobacteriaceae isolates consisted mainly of the genus *Enterobacter*. A total of 31 ESBL-producing Enterobacteriaceae were isolated in this study. All but one of these isolates were recovered from the ESBL medium (sensitivity 97%).
Conclusion: The chromogenic ESBL medium is a sensitive medium for the detection of ESBL-producing Enterobacteriaceae. Regarding the specificity, the growth of non-fermenting Gram-negative rods is a frequent finding. However, use of the cytochrome oxidase test enables rapid identification of most of these bacteria. A more important issue is the growth of Enterobacteriaceae with other resistance mechanisms then ESBL production. This makes the use of confirmatory testing obligatory for species known to harbour these non-ESBL resistance mechanisms.

P887 Comparative performance of three phenotypic confirmatory Etest strips for the detection of extended-spectrum β-lactamases-producing Enterobacteriaceae in Belgian hospitals

Y. Glupczynski, C. Behrin, C. Bauraing, P. Bogaerts (Yvoir, BE)

Objectives: Criteria for ESBL detection have only been established for a limited number of Enterobacteriaceae species (*E. coli*, *Klebsiella* spp., *Proteus mirabilis*) by the Clinical Laboratory Standards Institute (CLSI). ESBL production in other species is clinically significant, but remains under reported owing to the lack of consensus guidelines. We evaluated the performance of 3 phenotypic confirmatory Etest strips to detect ESBL producers among a large collection of Enterobacteriaceae clinical isolates collected in Belgian hospitals.
Methods: 332 ESBL-producing Enterobacteriaceae clinical isolates (149 *E. aerogenes*, 131 *E. coli*, 31 *K. pneumoniae* 11 *E. cloacae*) obtained in 2006 from 86 centres were investigated. ESBL production was assessed by multiplex PCR analysis (TEM, SHV, CTX-M) and DNA sequencing. Three Etest strips containing cefotaxime (TX), ceftazidime (TZ), and cefepime (PM) alone and in combination with clavulanate (CL) were evaluated. Etest results were considered positive according to the CLSI criteria established for *E. coli*, *Klebsiella* spp. and *P. mirabilis* (i.e., a > 3 two-fold concentration decrease in MIC tested in combination with clavulanate versus its MIC when tested alone) or when a deformation

of the inhibition ellipse was observed. Indeterminate Etest results were considered negative.

Results: Isolates were found to possess blaTEM (n = 300; 153 with TEM-24 type) blaSHV (n = 31) with SHV-4, -5, and -12 as the most common types) and CTX-M (n = 35; CTX-M-15, M-1, M-9, M-14, M-2 as the most frequent). Ability of Etest strips in detecting ESBL phenotypes in all species isolates was as follows: PM/PM-CL (95.8%), TZ/TZ-CL (54.8%), and TX/TX-CL (53.3%). Against *Enterobacter aerogenes* and other AmpC-positive species (n = 365), accurate ESBL detection was consistently achieved only by PM/PM-CL (89.7%; 93.2% in *E. aerogenes*) while Etest results were mostly indeterminate due to off scale values for TX and TZ-based Etests. Against non-AmpC producing species (n = 367), sensitivity of ESBL detection was: TZ/TZ-CL (92.8%), TX/TX-CL (92.2%) combination of both TZ and TX ESBL Etests (96.4%).

Conclusion: Etest PM/PML appears as the best single phenotypic confirmatory Etest performance for ESBL detection in this collection of Enterobacteriaceae containing a large proportion of AmpC producing isolates. Combination of TZ-TZ-CL and TX-TX-CL Etest strips is well suited for the detection of ESBLs in *E. coli* and in *Klebsiella* spp.

P888 Rapid detection of extended-spectrum β-lactamase production

S.P. Gregory, S. O'Hara, J. Duffy (Salisbury, Loughborough, UK)

Objectives: The aim of this study was to create a method for the rapid detection of extended spectrum β-lactamases (ESBLs) from Gram-negative culture isolates using AK rapid technology. Adenylate kinase (AK) is novel and sensitive microbial cell marker which can be used to rapidly detect the growth of microorganisms without the need for conventional culture. The rapid AK method results would be compared to a phenotypical ESBL-confirmatory assay which takes 18–24 hours.

Methods: A panel of culture isolates comprising ESBL positive and negative strains were screened by inoculating two MIC-Strip ESBL test strips obtained from Merlin Diagnostics (Bornheim, Germany) according to the manufacturers instructions. The first strip was incubated overnight at 35–37°C and the result read visually. The phenotypical confirmation test is a $\geqslant$3 two-fold decrease in MIC of the suspected organism to cefpodoxime in the presence of a fixed concentration of clavulanic acid, versus its MIC when tested alone. The second strip was incubated at 37°C for 5 hours after which 0.05 mL was removed from each well, diluted 1:4 in Mueller-Hinton II broth and 0.1 mL of this diluted sample was then added to a microtitre plate.

The samples were then processed on a microplate luminometer with automated injection of the following reagents:

0.05 mL mixed bacterial lysis agent/purified ADP – for a 5 minute incubation time the adenylate kinase in the sample converts ADP to ATP.

0.05 mL Luciferase/Luciferin Reagent – followed by a 1 second read.

The results of each sample were then assessed according to an in-house devised algorithm and classified as 'Growth' or 'No Growth' and interpreted in the same way as the MIC-Strip ESBL test.

Results: There was 100% agreement between the rapid AK method and the MIC-Strip ESBL for all the organisms tested. All the ESBL positive and negative strains were correctly identified by both methods.

Conclusion: This new rapid method correctly predicted a positive/negative result for phenotypical ESBL confirmation within 5 hours.

P889 Comparison of VITEK 2 generated extended spectrum β-lactamase phenotypes to double-disc test results in Enterobacteriaceae

L. Naumiuk, B. Rybak, G. Brzezinski, E. Naumiuk, A. Samet (Gdansk, PL)

Objectives: The aim of the study was to compare results of extended spectrum β-lactamase (ESBL) detection suggested by ESBL phenotypes generated by VITEK 2 (bioMerieux) advanced expert system (AES) to the results of double disk tests (DDT).

Methods: We retrospectively studied AES generated phenotypes suggesting ESBL presence in Enterobacteriaceae and results of DDT routinly performed to confirm the presence ESBL enzyme. Modified DDT was done with cefepime, cefotaxime and amoxicillin+clavulanic acid disks. AES phenotypes which included ESBL alone and/or ESBL together with other β-lactams phenotypes were taken into analysis. Analysis was performed by our laboratory information system – Promic (Antrez).

Results: From May to November 2007 we performed 928 Enterobacteriaceae susceptibility tests using VITEK 2 cards GN021 or GN041. In 140 isolates – among others 46 *Enterobacter cloacae*, 29 *Escherichia coli*, 16 *Klebsiella pneumoniae*, 13 *Citrobacter freundii* – AES suggested detection of ESBL phenotype although DDT confirmed its presence in only 66 isolates. The highest agreement between the AES and DDT was in *E. coli* (100%) and *Klebsiella* spp. (99%). The least correlation was noted in *E. cloacae* (46 phenotypes/6 confirmed), *Morganella morganii* (10/1) and *Serratia marcescens* (10/2). In 64 isolates when AES suggested ESBL phenotype as a sole β-lactams phenotype DDT confirmed ESBL production in 48 of them. In this case agreement between the AES and DDT with regard to species was the same.

Conclusion: VITEK 2 AES proposed phenotypes which suggest ESBL presence do not need confirmation in *E. coli* and *Klebsiella* spp. The same phenotypes in chromosonal cephalosporinase producers like *Enterobacter*, *Citrobacter*, *Serratia* and *Morganella* always need confirmation by another method for example modified DDT.

P890 Performance of VITEK 2 ESBL confirmation test in a set of well characterised clinical isolates of *E. coli*, K. pneumonia, *K. oxytoca* and *Enterobacter* species. An alternative for double disc testing

Y.J. Debets-Ossenkopp, N. al Naiemi, S. Lee, J.L. Murk, J.A. Mulder, C.M.J.E. Vandenbroucke-Grauls (Amsterdam, NL)

Objectives: Severe infections caused by ESBL-producing microorganisms are becoming more common all over the world. Rapid and accurate ESBL detection has to be pursued by routine clinical laboratories in order to offer assistance in guided antibiotic therapy. Phenotypic ESBL confirmation tests must be performed on isolates that, based on initial antimicrobial testing, are suspected to produce ESBL. We evaluated the performance of the VITEK 2 ESBL confirmatory test on two sets of clinical isolates.

Methods: Strains; First set: 31 *E. coli* (ECO), 3 *Klebsiella pneumoniae* (KPN), 1 *Klebsiella oxytoca* (KOX), 19 *Enterobacter* spp., ESBL positive (+) and 7 *Enterobacter* spp. ESBL negative (–) confirmed by molecular methods. Second set: 50 *Enterobacter* spp. ESBL(–) or (+), phenotypic confirmation with Double Disk Synergy Test (DDST), Double Disk Combination Test (DDCT) and ESBL E-test. Confirmatory tests: VITEK 2 ESBL card (in conjunction with VITEK 2 GNS N048), DDST, DDCT and E-test cefepime.

Table 1.

Strains	Sequencing		DDST/DDCT/E-test		VITEK 2 ESBL test	
	ESBL+	ESBL–	ESBL+	ESBL–	ESBL+	ESBL–
First set						
E. coli (31)	31		28	3	28	3
K. pneumoniae (3)	3		3		3	
K. oxytoca (1)	1		1			1
Enterobacter (26)	19		18	1	17	2
		7		7	1	6
Second set						
Enterobacter (50)	ND			27		27
	ND		10*		10*	
	ND			13*	13*	

* MICs cefotaxime and ceftazidime >1 mg/L.

Results: see Table 1. Three out of 31 ECO were misidentified (2/3 SHV-12, 1/3 CTXM-2) with VITEK 2 ESBL test as well as with DDST,

DDCT and E-test. All *Enterobacter* isolates ESBL (+) strains, that were confirmed by PCR and sequencing and/or by phenotypic confirmation, were correctly identified with the VITEK 2. One sequenced *Enterobacter* spp. ESBL (–) was false positive with the VITEK 2. In 13 out of 40 ESBL (–) strains (phenotypic confirmation), VITEK 2 was positive.
Conclusion: For the ECO, KPN the VITEK 2 ESBL test performed as well as the DDST, DDCT and E-test. For *Enterobacter* isolates performance of the VITEK 2 ESBL test needs further evaluation.

P891 Effect of Oxgall on the imipenem-disc Hodge test in screening metallo-β-lactamase-producing Gram-negative bacilli

K. Lee, C.K. Kim, D. Yong, J.H. Yum, Y. Chong (Seoul, KR)

Objectives: Increasing prevalence of carbapenemase-producing Gram-negative bacilli (GNB) has been a concern, but only a few phenotypic screening tests have been reported. We have been using the imipenem (IPM)-disk Hodge (cloverleaf) test to screen metallo-β-lactamase (MBL)-producing GNB. As the original Hodge test using Mueller-Hinton agar (MHA) was low in reproducibility, we now use MacConkey agar with much improved results. We investigated responsible ingredient that improve the results with MacConkey agar.
Methods: Materials used were MHA, MacConkey agar, 10-ug imipenem disk, Oxgall, starch and lactose. Bacterial strains used were those with known β-lactamases and clinical isolates. The surfaces of test media were inoculated using *E. coli* ATCC 25922 as was the CLSI disk diffusion test. After drying the surface, test organism was heavily streaked from the centre to the periphery of the plate and an IPM disk was placed at the centre. After overnight incubation, decrease of inhibition zone along the streaked line was measured and decrease of ⩾3 mm was arbitrarily interpreted as positive.
Results: Preliminary comparison using VIM-2-producing *Pseudomonas aeruginosa* (PAE, n = 4) and *Acinetobacter* spp. (ACI, n = 3) showed that 3 of 7 isolates were Hodge test positive by using MHA, but all were positive by MacConkey agar. Addition of 1% lactose or starch to MHA did not change the results. With 3 IMP-1-producing and 4 VIM-2-producing isolates, addition of 0.2% Oxgall did not improve the results, but addition of 2% changed the mean inhibition zone from 4.2 mm to 8.7 mm. OXA type carbapenemase-producing ACI gave positive results, although the reduction of inhibition zone was less than those with MBL-producing isolates. MHA-containing 2% Oxgall showed positive results with 26 of 28 OXA-type carbapenemase-producing ACI. On MacConkey agar, ESBL- or plasmid-mediated AmpC-producing isolates did not show positive Hodge test. blaTEM-107-cloned *E. coli* showed that the β-lactamase activity was much higher when grown in the Oxgall 2 mg/ml-containing ZYP-5052 medium, suggesting bile may enhance release of β-lactamase into the surrounding medium.
Conclusion: Bile is the ingredient, which improve performance of imipenem-disk Hodge test in the detection of MBL-producing isolates.

P892 Comparison of performance of MacConkey agar and Mueller-Hinton agar in imipenem-Hodge test

S.G. Hong, S.K. Hong, H. Lee, S.H. Jeong, W. Song, K. Lee, Y. Chong (Gyeonggi-do, Busan, Seoul, KR)

Objectives: Imipenem-Hodge test for screening of carbapenemases is usually performed with Mueller-Hinton agar (MHA). However, some metallo-β-lactamases (MBL) producing strains show negative results. The aim of this study was to compare the performance of MacConkey agar (MCA) and MHA in imipenem-Hodge test.
Methods: The strains comprised 21 MBL-producers (14 IMP-producing *Pseudomonas aeruginosa*, 3 VIM-producing *P. aeruginosa*, 1 IMP-producing *Acinetobacter baumannii*, 1 VIM-producing *A. baumannii*, 1 SIM-producing *A. baumannii* and 1 VIM-producing *Alcaligenes faecalis*) that were not clearly positive from imipenem-Hodge test with MHA. Twenty nine isolates of non-carbapenemase-producing Enterobacteriaceae (AmpC β-lactamase producers, and/or ESBL producers) were also tested. The surfaces of MHA and MCA plates were inoculated with a lawn of indicator strain, *Escherichia coli* ATCC 25922, according to CLSI disk diffusion method. After drying the agar surface, a test strain was heavily streaked from the centre of the plate to the periphery and a 10 μg imipenem disk (Becton Dickinson) was placed at the centre. After overnight incubation at 35°C, presence of definite growth of indicator organism in the inhibition zone along the test strain was interpreted as positive. The two results from MHA and MCA plate were compared.
Results: With MHA, 9 of 21 MBL-producers showed negative results and 7 were weak positive, while definite positive results were obtained from only 5 strains. However, with MCA, 18 of 21 MBL-producers showed positive results and 3 were weak positive. All of the other non-carbapenemase producers were negative with MHA. However, with MCA, one AmpC-producing *E. coli* showed clearly positive indentation.
Conclusions: Imipenem-Hodge test with MCA were more sensitive and easier to read the results. The use of MCA should be helpful to clinical laboratories for the detection of MBL-producing bacteria.

P893 Prevalence and detection of metallo-β-lactamase-producing *Pseudomonas aeruginosa* strains from clinical isolates in Iran.

H. Rezaei Yazdi, G. Behzadian Nejad, S. Najar Peerayeh, M. Mosatafaei (Tehran, IR)

Introduction: *Pseudomonas aeruginosa* is an opportunistic human pathogen and a cause of nosocomial infection, especially in immunocompromised patients. Carbapenems mainly imipenem and meropenem are potent agents for the treatment of infections caused by multidrug-resistant *P. aeruginosa*. Resistance to carbapenems in *Pseudomonas aeruginosa* is often due to loss of the OprD porin. The up-regulation of Mex AB-OprM efflux pump system compromises the activity of antibiotics including meropenem. The production of MBL is another mechanism for resistance to β-lactams including carbapenems.
Materials and Methods: The 126 isolates used in this study were selected from variety clinical specimens collected during 2006 at two university hospitals in Tehran, Iran. The isolates were identified by standard laboratory methods as *Pseudomonas aeruginosa*.The MICs for antimicrobial agents were determined according to the guidelines of the National Committee for Clinical Laboratory Standards. *P. aeruginosa* strains that showed resistance or reduced susceptibility to imipenem and/or ceftazidime were selected for further evaluation of MBL production by Etest MBL strips.A reduction of imipenem or ceftazidime MICs by 3 two fold dilution in the presence of EDTA was considered as positive.PCR analysis for detection of VIM-type MBL and IMP-type MBL was carried out with specific primers. Positive controls (MBL-producing strains)were used for PCR and Etest MBL strips.
Results: Of the 126 nonduplicate isolates tested, seventy strains that showed resistance or reduced susceptibility to imipenem and/or cetfazidime, were selected. Seventy isolates that showed resistance or reduced susceptibility to imipenem and/or ceftazidime were screened for presence of MBLs by Etest MBL strips. Etest MBL strips showed a positive results for eight *P. aeruginosa* strains. Finally, the 8 strains that were positive by Etest MBL strips gave a positive result with PCR.These eight strains carried a bla VIM-type gene, and bla IMP-type gene not detected.
Conclusion: The results from this research demonstrated that approximately, MBL-positive strains had multidrug-resistant(MDR). These data demonstrate that VIM-type gene are the most prevalent MBLs among clinical specimens of *P. aeruginosa* in Iran. Reports of acquired MBLs are increasing world wide among both non fermenters and enterobacteria. Therefore, suitable therapeutic methods should be used to prevent the spread of these resistances.

P894 **Evaluation of the Cica-Beta Test for routine detection of AmpC cephalosporinase hyperproduction and extended-spectrum β-lactamase production**

L. Blairon, S. Van den Wijngaert, M. Reynders, O. Vandenberg, F. Crokaert, A. Dediste (Brussels, BE)

Objectives: Distinction between ESBL and AmpC cephalosporinase hyperproduction (AHP) among resistant strains of Enterobacteriaceae is not easy in routine with automated identification systems, because of the low performances of the expertise in recognising such phenotypes. Cica-Beta Test (CBT) a new chromogenic method is available for rapid detection of AHP, ESBL, and metallo-β-lactamases (MBL). In the present study, we evaluated the performances of CBT in the detection of AHP and ESBL.

Material and Methods: All isolates were tested on VITEK 2. ESBL detection was performed using chromID ESBL Agar and CBT-CVA, in comparison to combined double disks, according to CLSI guidelines. AHP was assessed by CBT-C compared to detection of synergy between 3rd-generation cephalosporins (3GC) and either boronic acid or cloxacillin. We also tested CBT-I as a screening method able to detect either AmpC, ESBL, penicillinases or MBL. CBT-MBL was not tested because of the low incidence of MBL-producing bacteria in our institution. Inclusion criteria for Enterobacteriaceae were defined by (a) a positive ESBL-screening or expertise on VITEK 2; (b) a resistance up to 2nd-generation cephalosporins in non-natural AmpC-producers or a resistance up to 3GC in constitutive AmpC-producers.

Result: Among 40 consecutive stains, 23 were ESBL+, 26 were AHP+. Sensitivity of CBT-CVA and CBT-C was 83% and 54% respectively, and specificity was 65% and 29%. The CBT-I detected a resistance mechanism in 72%. A discordance between a negative CBT-I and a positive CBT-CVA or CBT-C was encountered in 12 cases. ChromID ESBL was positive for all ESBLs, but the specificity was very low (41%).

Conclusions: The goal aimed by CBT as a screening test for rapid detection is not reached because of the importance to pick colonies at boundary of inhibition zone of a 3GC; however, these step requires 18–24 h of reincubation after primoculture. The CBT is difficult to read with few contrast between a positive result and a negative one. The CBT lacks robustness and isolates must be picked in 5 minutes after removing from the incubator, when the β-lactamase production is maximal. Finally, the test is very expensive, and shows poor performances. We observed discordances between the screening test and the specific CBTs. For those reasons, CBT is not useful in routine. In comparison, a chromogenic medium such as ChromID ESBL Agar remains a cost-effective screening test for ESBL with a maximal negative predictive value.

Carbapenem resistance – Part 1

P895 **First detection of transferable metallo-β-lactamases in the Netherlands**

N. al Naiemi, M.C. Rijnsburger, P.H.M. Savelkoul, M. Llamas, M. Sparrius, C.M. Vandenbroucke-Grauls, Y.J. Debets-Ossenkopp (Amsterdam, NL)

Objectives: Metallo-β-lactamases (MBLs) are of special importance due to their role in microbial resistance to β-lactam antimicrobial agents, especially carbapenems. The prevalence of *Pseudomonas aeruginosa* strains that produce MBLs is increasing worldwide. Currently, nothing is known on the prevalence of these strains in The Netherlands. We determined the prevalence and the type(s) of MBLs produced by strains of *Pseudomonas* species isolated at the VU University Medical Center, in Amsterdam, The Netherlands.

Methods: During the first 7 months of 2007, the susceptibility profiles of 650 isolates from 329 patients were analysed. Isolates with decreased susceptibility to imipenem- and/or meropenem were tested for the production of MBL with MBL E-test. Site of infection/colonisation, and location of the patient in the hospital at the moment of strain isolation were recorded. DNA fingerprinting of the strains was performed with amplified fragment length polymorphism analysis (AFLP) to determine clonal relations. Transfer of resistance was investigated with conjugation experiments. The presence of VIM MBL genes was determined by PCR with generic primers. Further molecular characterisation of resistance genes confirmed the resistance pattern.

Results: Of 329 patients, 12 (3.6%) carried a MBL-positive *Pseudomonas* strain. Six strains were associated with clinical infection. The urinary tract was the most common site of infection. Epidemiological and molecular analysis showed no indications for a clonal outbreak in our hospital. Results of the conjugation experiment showed that these resistance genes were transferable. VIM PCR confirmed the production of VIM MBL in *Pseudomonas* isolates of two patients.

Conclusion: To the best of our knowledge, this is the first report that describes infections caused by MBL-producing *Pseudomonas* spp. strains in The Netherlands. Although the prevalence of metallo-β-lactamases is yet low, these results signal the need for development of accurate diagnostic tests by clinical laboratories to detect the presence of these resistance genes, so that specific isolation precautions can be taken to control their dissemination.

P896 ***Pseudomonas aeruginosa*** **producing VIM-2 metallo-β-lactamase in Cantabria, Spain.**

M.C. Rodriguez, B. Ruiz, C. Rodriguez, L. Martínez-Martínez (Santander, ES)

Background: Carbapenem resistance rates of *P. aeruginosa* (Pae) in Spain and in other countries are similar, but strains producing metallo-β-lactamases (MBL) are quite uncommon in Spain. We report Pae producing VIM-2 in Cantabria, Spain.

Methods: All Pae isolates intermediate/resistant (I/R) to imipenem (IMP) and/or meropenem (MPM) (1 per patient) in Jan2004-Dec2006 were tested for MBL production. Susceptibility studies were done by Microscan, ETest strips and microdilution (following CLSI instructions; $\geqslant$8-fold decrease in the MIC of IMP or MPM combined with 0.4mM EDTA plus 0.04mM 1,10-phenantroline, compared with the MIC of the carbapenem alone indicated MBL production). MBL encoding genes were detected by a multiplex PCR (Mendes R., et al, 2007); PCR and sequencing were used for identification of blaVIM-2 and characterisation of type 1 integrons. Clonal relation of isolates was tested by Rep-PCR. Hydrolysis of IMP was detected by spectrophotometry.

Results: The blaVIM-2 gene was detected by PCR in 10 isolates for which the MICs of IMP and MPM ranged 32–128 and 16–32 μg/ml respectively. In all cases the strains were I/R to ceftazidime, cefepime, gentamicin, tobramicin and ciprofloxacin. 9/12 strains were amikacin-R. All isolates, except 1, were aztreonam susceptible. All isolates had a single Rep-PCR pattern. Hidrolysis of IMP in MBL(+) isolates ranged 0.1622 to 0.2159 nmol/min/μg protein and was abolished in the presence of 5 mM EDTA. An integron with 5′CS-aac(6)-blaVIM-2-putative transposase-enconding gene-3′CS was observed.

Conclusions: We have documented in Northern Spain clonally-related multiresistant *P. aeruginosa* strains producing type-1 integrons encoding blaVIM-2 and aminoglycoside-modifying enzymes.

P897 **First report of a** ***Morganella morganii*** **clinical isolate producing VIM-2 carbapenemase**

G.J. Da Silva, O. Cardoso, S. Domingues, G. Bento, G. Ribeiro (Coimbra, PT)

IMP and VIM metallo-β-lactamases (MBL) are the most frequent carbapenemases, hydrolysing all β-lactams except aztreonam. They are often encoded by gene cassettes inserted into class 1 integrons. They are mostly disseminated among Gram-negative non-fermenters and have been rarely found in Enterobacteria. In 2004, a *Morganella morganii* isolate was collected at the University Hospitals of Coimbra, Portugal, from a patient's urine with an unusual susceptibility profile for this species. The aim of this work was to investigate the mechanism responsible for the reduced susceptibility to imipenem observed in this

isolate. Susceptibility tests were confirmed by the disc diffusion tests. MICs were determined by Etest. A synergy test with imipenem and EDTA was performed for detection of a MBL phenotype. Conjugation experiments were done by the filter mating method. Plasmid isolation was performed by using Plasmid Midi kit (Qiagen). A multiplex PCR was used for detection of VIM and IMP genes. Class 1 integrons were detected with specific primers 5′CS and 3′CS.
The isolate was resistant to amoxicillin, cefoxitin, cefuroxime, norfloxacin, ciprofloxacin and susceptible to aztreonam and amikacin. It showed decreased susceptibility to cefotaxime, meropenem, imipenem (MIC= 3 mg/L) and ceftazidime (MIC= 6 mg/L). The double-disk synergy test with imipenem- and EDTA-containing disks suggested the presence of a MBL. A multiplex PCR with IMP and VIM specific primers with positive controls for VIM-2 and IMP-5 (1,2), and further sequence analysis of the unique amplicon ca 800 bp, confirmed the presence of a VIM-2. Combinations of 5′CS, 3′CS and VIM primers were used to study the surrounding genetic context. A class 1 integron was amplified, integrating a unique cassette of aadB allele, unexpectedly not the blaVIM. The amplicon obtained with 5′CS and VIM reverse primers carried the aacA7 cassette, followed by the VIM-2 cassette. It was not possible to amplify a segment with 3′CS primer, suggesting that this integron has an unusual structure. A plasmid >10 Kb was found and blaVIM was amplified, but all the conjugation experiments were unsuccessfully using *E. coli* K102 as recipient.
To our knowledge, this is the first identification of VIM-2 in *M. morganii* worldwide. Apparently, spread of this MBL through enterobacterial population is low and it remained in this hospital a sporadic case, but the low carbapenem MICs found can mask the real situation.

P898 First occurrence of carbapenem-resistant *Pseudomonas aeruginosa* isolates producing VIM-2 metallo-β-lactamase in a Tunisian university hospital

W. Mansour, O. Bouallegue, D. Bettaieb, S. Dahmen, L. Poirel, P. Nordmann, N. Boujaafar (Sousse, TN; Paris, FR)

Objective: To characterise the β-lactamase-associated mechanisms of resistance of carbapenem-resistant *Pseudomonas aeruginosa* isolates recovered at the University Hospital Sahloul in Tunisia during a two-years period.
Methods: Seventy-five non-repetitive carbapenem-resistant *P. aeruginosa* isolates were recovered from November 2003 to May 2006. Metallo-β-lactamase (MBL) genes were searched by phenotypic and genotypic analyses, in particular genes for IMP-1, VIM-1 and VIM-2. Genotyping was done by ERIC-PCR. Amplification of class 1 integrons was performed by PCR with specific primers.
Results: All *P. aeruginosa* isolates were resistant to most β-lactams tested including imipenem. Five *P. aeruginosa* isolates possessed the blaVIM-2 gene. They had been isolated from blood culture and urine of patients hospitalised in the intensive care units or urology ward. Genotyping revealed that the VIM-2-positive *P. aeruginosa* isolates belonged to a single clone. The blaVIM-2 gene was likely located on the chromosome of those strains, and found to be inserted in a class 1 integron. The other carbapenem-resistant *P. aeruginosa* isolates (corresponding to three distinct clones) did not produce any carbapenemase.
Conclusion: This is the first report of dissemination of VIM-2 in *P. aeruginosa* in Africa. The occurrence of MBL determinants among *P. aeruginosa* isolates in Tunisia is worrying and further underlines the wide spread of VIM-2 worldwide.

P899 Genetic characterisation of the new blaVIM-18 and comparative antimicrobial susceptibility profile of VIM-18 with highest homologous VIM-variant, VIM-2: report from the SENTRY Antimicrobial Surveillance Program

M. Castanheira, R. Mendes, J. Bell, H. Sader, R. Jones (North Liberty, US; Adelaide, AU)

Objective: To characterise the genetic context of a new blaVIM-variant from India; and to compare the antimicrobial susceptibility (S) profiles of *E. coli* carrying recombinant plasmids harbouring blaVIM-18 and blaVIM-2. We recently found that VIM-producing *P. aeruginosa* were highly prevalent in Indian medical centres (55% of the carbapenem [CARB]-resistant [R] isolates) and VIM-2 was the most common VIM-variant (38.6%).
Methods: As part of the SENTRY Program, CARB-R isolates were screened for metallo-β-lactamases (MBL). Positive isolates were then amplified and sequenced with MBL internal primers and primers targeting conserved structures of class 1 integrons. blaVIM-2 and the new blaVIM were amplified, cloned into PCRScript plasmid and transformed in *E. coli* XL1 Blue. Colonies were selected with chloramphenicol (30 mg/L) and ceftazidime (4 mg/L). The presence and orientation of blaVIM was confirmed by PCR and sequencing. S testing was performed by E-test (ABBIODISK, Solna, Sweden). The region flanking the MBL integron was amplified using a degenerate primer approach. Plasmid contents analysis was also carried out.
Results: *P. aeruginosa* isolate 243–31C was recovered from a sputum specimen in Kolkatta, India (2006). PCR and sequencing showed the presence of new blaVIM variant, named blaVIM-18 (Lahey Clinic). The deduced VIM-18 protein comprised 262 amino acids showing 74.3 to 99.2% identity to other VIM enzymes. VIM-18 was identical to VIM-2, except for the deletion of four amino acids. The MBL active sites were all present. The *E. coli* carrying blaVIM-18 showed lower MIC values for ampicillin, cefoxitin, cephalothin and ertapenem (3-, $\leqslant$6-, $\leqslant$4- and 4-fold, respectively) when compared to those obtained from the *E. coli* carrying blaVIM-2, while similar MIC values were noted for imipenem, meropenem, piperacillin, cefotaxime, ceftazidime and cefepime. blaVIM-18 was the only R gene cassette in a class 1 integron that was flanked upstream by a resolvase gene (tnpR) from Tn5051-like. Further analysis showed that this isolate carried no plasmid.
Conclusions: VIM-18 displayed reduced activity to some β-lactams, while retaining similar activity against anti-pseudomonal agents when compared to VIM-2. Thus, the 12-bp deletion in VIM-18 seems to have little effect in the activity against target CARB and anti-pseudomonal cephems. VIM-18 was found in one *P. aeruginosa* isolate among numerous VIM-2-producing strains, and it appears to be an evolutionary derivative.

P900 High carbapenem resistance among *Pseudomonas aeruginosa* from India: a national epidemic of multiple metallo-β-lactamase clones (VIM-2, -5, -6, -11 and new VIM-18)

M. Castanheira, J. Bell, R. Jones, D. Mathai, J. Turnidge (North Liberty, US; Adelaide, AU; Vellore, IN)

Objectives: We assessed the prevalence of MBL-encoding genes among carbapenem-resistant *P. aeruginosa* isolates recovered in India during 2006. In addition, class 1 integrons harbouring MBL genes were amplified and compared and MBL-positive isolates were molecular typed to evaluate clonal dissemination.
Methods: A total of 282 *P. aeruginosa* were consecutively collected in 10 Indian medical centres and tested by CLSI broth microdilution methods. Isolates resistant to imipenem or meropenem (MIC, >8 mg/L) were screened for MBL-encoding genes by Real-time PCR. Positive samples were tested with primers targeting the class 1 integron conserved structures anchoring in the MBL genes. Amplicons generated were sequenced on both strands and MBL isolates ribotyped for possible clonality.

Results: Among the 282 isolates, 96 (34%) showed carbapenem resistance and MBL genes were detected in 53 strains (19% of total; 55% of carbapenem-resistant). MBL-producing *P. aeruginosa* were detected in 9 of 10 hospitals. Five blaVIM genes were found, including a new variant named blaVIM-18. This new MBL gene showed a 12 bp deletion (position 428) when compared to blaVIM-2 and was carried as a single gene cassette in a class 1 integron. VIM-2 producing isolates were most common (38 strains) and were detected in 8 medical centres. VIM-6 was identified in 12 isolates from 4 sites. VIM-5, VIM-11 and VIM-18 were found only once. Two medical centres had 3 distinct MBL types and other 2 had 2 MBL types. Wide genetic diversity was noted among MBL-carrying *P. aeruginosa* with 21 and 10 ribotypes seen among VIM-2- and -6-producers, respectively. Seven clones were found in ⩾1 participant hospital and 6 clones were noted within institutions. blaVIM-6-carrying integrons of 3.5 and 5 Kb (5 and 7 isolates, respectively) were detected and 2 sites had both blaVIM-6 integron types.

Table.

Site	CARB-R[a]/ MBL (%)	MBL types (No. of isolates)	MBL clonality		
			Intra	Inter	No. of clones
Kolkatta	30/22	VIM-2 (3), -5 (1), -18 (1)	0	2	2
Indore	42/42	VIM-2 (3), -6 (5)	1	2	3
New Delhi	34/18	VIM-2 (8)	1	3	4
Trivandrum	11/11	VIM-6 (2)	1	0	1
Hyderabad	51/17	VIM-2 (3), -6 (2)	1	3	4
Chennai[b]	46/0	None	–	–	–
Kochi	30/20	VIM-2 (5)	0	2	2
Manipal	30/20	VIM-2 (10)	2	3	5
Mumbai	30/22	VIM-2 (3), -6 (2), -11 (1)	0	3	3
Rajkot	25/25	VIM-2 (4)	0	1	1

a. CARB-R: carbapenem-resistant; b. Clones of non-MBL CARB-R *P. aeruginosa* were documented and VIM-2 by Toleman et al. (2007) from a 2003 isolate.

Conclusions: MBL-producing isolates have recently been reported in India, but limited data exists on the prevalence and characterisation of MBL-encoding genes. In this study we show that MBL-producing *P. aeruginosa* are epidemic in India with a great diversity of MBL-types (5 VIM types, including new VIM-18). In addition, different MBL-carrying integrons were observed, suggesting widespread dissemination of MBL-carrying mobile elements. Carbapenem resistance rates among *P. aeruginosa* were elevated and were principally caused by MBL production (57%).

P901 blaVIM-2-carrying integron among Enterobacteriaceae isolates in Mexico: report from the SENTRY Antimicrobial Surveillance Program

L. Deshpande, R. Jones, R. Morfin-Otero, E. Rodriguez, H. Sader (North Liberty, US; Guadalajara, MX)

Objectives: To characterise metallo-β-lactamase (MBL)-producing Enterobacteriaceae (ENT) strains isolated in a Mexican hospital and to evaluate the genetic context of the MBL-encoding genes. Carbapenems are generally very active against ENT but resistance has been emerging and has increased rapidly in some geographic areas due to the dissemination of MBL-carrying integrons.

Methods: ENT collected as part of the SENTRY Antimicrobial Surveillance Program were susceptibility (S) tested against >25 antimicrobials by CLSI broth microdilution methods. Isolates with imipenem and/or meropenem MIC at ⩾2 mg/L were screened for MBL production by the disk approximation test; positive isolates were further characterised by PCR and gene sequencing. Primers targeting the class 1 integron conserved structures anchoring MBL genes were used to reveal integron structure. Amplicons generated were sequenced on both strands and MBL-producing isolates were evaluated for possible clonality by PFGE.

Results: Three isolates, all from one hospital in Mexico, exhibited positive MBL-screening test results. Two *E. cloacae* (2005 and 2007) and one *K. oxytoca* (2006) yielded a PCR product with blaVIM primers. The MBL gene was embedded in a 2.8-Kb class 1 integron in all strains. Sequencing revealed that blaVIM-2 was located in the first position of the integron followed by 2 gene cassettes: an open reading frame (orf) and an aminoglycoside acetyl transferase gene (aacA7). The 400-bp orf showed low homology with other DNA sequences; however the deduced amino acid sequence showed active domains of a chorismate mutase enzyme from *Pseudomonas fluorescens*. The degree of carbapenem resistance varied significantly among these VIM-2-producing isolates. The *E. cloacae* isolates were epidemiologically unrelated and one strain was S to both imipenem and meropenem (ertapenem also S; 0.12 or 0.25 mg/L) based on current CLSI breakpoints of ⩽4 mg/L (see Table).

Organism	MIC (mg/L)[a]: IMI	MER	ERT	CPM	AMK	TET	CIP	TIG
K. oxytoca (13268A)	>8	>8	>8	4	⩽4	4	1	0.25
E. cloacae (3876A)	4[b]	1[b]	0.25[b]	2	⩽4	⩽2	⩽0.03	0.5
E. cloacae (1068D)	8	1[b]	0.12[b]	2	8	>8	0.5	0.5

a. IMI = imipenem, MER = meropenem, CPM = cefepime, AMK = amikacin, CIP = ciprofloxacin, TIG = tigecycline.
b. Indicates susceptible level carbapenem MIC results.

Conclusions: The finding of distinct ENT strains over a period of 3 years harbouring the same blaVIM-2-carrying integron indicates that this mobile genetic structure has become locally endemic. MBL-producing ENT may not be detected by clinical microbiology laboratories due to S-level carbapenem and other β-lactam MIC results, requiring new detection strategies or revised S breakpoints.

P902 Molecular typing indicates an important role of two international clonal complexes in the dissemination of VIM-producing *Pseudomonas aeruginosa* clinical isolates in Hungary

B. Libisch, B. Balogh, J. Paszti, G. Szabo, M. Gacs, M. Fuzi (Budapest, HU)

Objectives: VIM metallo-β-lactamase-producing serotype O11 or O12 *Pseudomonas aeruginosa* isolates infecting or colonising 19 patients from seven hospitals were reported from Hungary between 2003 and 2005. In this work we identified VIM-producing *Pseudomonas* spp. strains from Hungarian towns and hospitals where these resistance determinants had not been detected before. Our aim was to characterise these isolates by molecular and phenotypic tools and to investigate their epidemiological relationship.

Methods: We screened the isolates by EDTA-inhibition based phenotypic tests. blaVIM genes and class 1 integrons were detected by PCR and were sequenced. PFGE was performed by the method described by Poh et al. with modifications and MLST was carried out according to the protocol published by Curran et al.

Results: The newly identified *P. aeruginosa* MBL producing isolates could be assigned to serotypes O1, O11 and O12. All isolates proved multidrug-resistant; however, it is notable that all *P. aeruginosa* isolates remained susceptible to aztreonam by the current CLSI breakpoints. VIM-producing *Pseudomonas* spp. clinical isolates from two novel locations and hospitals in Hungary were identified, with the detection of three new blaVIM carrying integron types and the presence of the blaVIM-2 allele in Hungary. By applying various typing techniques

including multilocus sequence typing we revealed an important role of two international clonal complexes in the dissemination of blaVIM positive *P. aeruginosa* in hospitals in Hungary. We characterised a *P. aeruginosa* nosocomial clone with a singleton sequence type (ST313), too, that could have acquired blaVIM-2 and blaVIM-4 gene cassettes from a yet unidentified local gene pool in Hungary.

Conclusions: This is the first report of the occurrence of *P. aeruginosa* isolates from Hungary belonging to an international clonal complex initially described as BG11. In this study we have demonstrated a high diversity of MBL carrying integrons in Hungary and also propose that a combination of different factors, such as clonal spread and local acquisition of MBL genes may both contribute to the appearance of VIM positive *Pseudomonas* spp. strains in our country. This work was supported by the DRESP2 FP6 project.

P903 Dissemination of VIM-1- and VIM-4-producing *Acinetobacter baumannii* clones in an intensive care unit

A. Poulou, N. Spanakis, F. Markou, A. Ikonomidis, S. Pournaras, M. Diomidous, D. Vrizas, A. Tsakris, P. Rozi (Serres, Athens, Larissa, GR)

Objectives: *Acinetobacter baumannii* complex are opportunistic pathogen with increasing relevance in hospital infections, especially among patients hospitalised in intensive care units (ICUs). The organism often exhibits multidrug resistance and recently outbreaks of carbapenem-resistant isolates have been reported worldwide. Acinetobacters develop resistance to carbapenems through various mechanisms including production of metallo-β-lactamases (MBLs). In Europe, carbapenem resistance has been only sporadically attributed to the production of MBLs. We describe the dissemination of two different VIM-type MBLs among clonal carbapenem-resistant *A. baumannii* isolates in a Greek ICU.

Methods: During a two year period (April 2005-March 2007) 24 MBL-producing carbapenem-resistant *A. baumannii* isolates were collected consecutively from clinical specimens of separate patients hospitalised in a medical-surgical Greek ICU. The isolates were tested by MICs, phenotypic MBL testing and PFGE. PCR and sequencing assays were used for identification of carbapenemase genes and mapping of integrons. The location of the MBL genes was investigated by PCR, curing and hybridisation experiments.

Results: The MBL-producers had multidrug-resistant phenotypes and clustered in two distinct clones. All 19 isolates of the predominant clone contained blaVIM-1 along with blaOXA-58 and the intrinsic blaOXA-66 carbapenemase gene. The remaining 5 isolates belonged to a distinct clone and contained blaVIM-4 along with the intrinsic blaOXA-69 carbapenemase gene. In all cases blaVIM alleles were integrated in class 1 integron variable structures. *A. baumannii* isolates belonging to the two VIM-producing clones were also detected in the environment of the ICU. PCR, curing and hybridisation experiments indicated that the blaVIM alleles were chromosomally-located.

Conclusions: This study illustrates the spread of blaVIM-1 and blaVIM-4 MBL genes among different clones of multidrug-resistant A. buamannii in a well defined clinical setting.

P904 Prevalence of the blaIMP-1 gene in epidemiologically unrelated *Pseudomonas aeruginosa* isolates in Korea

J.S. Jin, J.W. Kim, C.H. Choi, J. Kim, Y.C. Lee, S.Y. Seol, D.T. Cho, J.C. Lee (Daegu, KR)

Objectives: Resistance to carbapenems is reported increasingly in *Pseudomonas aeruginosa* worldwide. This study investigated the resistance mechanisms against carbapenems and the molecular epidemiology of carbapenem-resistant *Pseudomonas aeruginosa* isolates from a Korean hospital.

Methods: A total of 79 carbapenem-resistant *P. aeruginosa* isolates were obtained from a tertiary hospital, located in Daegu, Korea. Antimicrobial susceptibility was determined by agar dilution methods. Resistance to carbapenems was characterised by a carbapenemase activity test and PCR amplification. The oprD gene was screended by PCR and the expression of OprD protein in the outer membrane was determined by SDS-PAGE. PFGE was performed to determine the clonal relatedness of *P. aeruginosa* isolates.

Results: The resistance rates of metallo-β-lactamase (MBL) producers against β-lactams, aminoglycosides and fluoroquinolones were significantly higher than those of MBL non-producers. Of the 79 carbapenem-resistant *P. aeruginosa* isolates, two MBL genes were detected in 50 (63.3%) isolates: blaIMP-1 in 40 isolates and blaVIM-2 in 10 isolates. Both the blaIMP-1 and blaVIM-2 genes were inserted in the gene cassettes of class 1 integrons, which were located on the plasmids. The oprD gene was not amplified in the 43 isolates: 23 of the 50 MBL producers and 20 of the 29 MBL non-producers. The remaining 36 oprD-positive isolates showed the reduced expression of OprD in the outer membranes. PFGE suggests that carbapenem-resistant *P. aeruginosa* isolates originated from the diverse clones.

Conclusion: We report the first outbreak of IMP-1-producing *P. aeruginosa* in Korea. A high prevalence of plasmid-borne MBL genes in epidemiologically unrelated *P. aeruginosa* isolates suggests the possibility of the intra- and interspecies dissemination of the MBL genes.

P905 Nosocomial outbreak caused by multidrug-resistant *Pseudomonas aeruginosa* producing IMP-13 metallo-β-lactamase in France

G. Cuzon, T. Naas, D. Tandé, R. Baron, C. Berthou, B. Lejeune, G. Rossolini, P. Nordmann (Kremlin-Bicetre, Brest, FR; Siena, IT)

Objectives: Acquired metallo-β-lactamases (MBLs) are emerging resistance determinants in *Pseudomonas aeruginosa* and other Gram-negative pathogens. Six different MBL-types: IMP, VIM, SPM, SIM, GIM and AIM, have been identified. IMP13 has only been described in Italy so far. Here, we describe the molecular characterisation of IMP13-producing *P. aeruginosa* strains from Brest, located West of France.

Methods: Carbapenem-resistant *P. aeruginosa* strains recovered were analysed for their DNA content (genomic or plasmid), by isoelectric focusing (IEF), imipenem hydrolysis, conjugation assays and pulsed-field gel electrophoresis of SpeI digested genomic DNA. PCR were performed for MBL-genes (IMP, VIM, SPM, SIM and GIM), blaKPC, blaTEM and blaSHV genes, the chromosomal class C β-lactamase blaAMPC and blaOXA-50 genes.

Results: An outbreak of *P. aeruginosa* showing a multidrug-resistant (MDR) phenotype (being susceptible only to colistin, amikacin, and fosfomycin) was observed, from February to May 2006 in the hematology ward of the hospital of Brest, France. The outbreak involved 4 patients with a total of 7 isolates, mostly from blood samples specimens. Analysis of isolates involved in the outbreak revealed MBL activity, and PFGE revealed clonal relatedness. A blaIMP-13 gene cassette inserted into a class 1 integron which also contained an aacA4 aminoglycoside resistance cassette encoding an AAC(6)-Ib enzyme was identified in all strains. The blaIMP-13-containing integron and its genetic environment was different from the epidemic IMP-13-producing *P. aeruginosa* isolate from Italy. The blaIMP-13 gene was chromosome-encoded. Epidemiological investigation revealed no recent trip to Italy of any of the patients and the only common point between these patients was their hospitalisation room. However, no overlap in hospital stay, nor the presence in the environment, since all the environmental samples were negative for MBL-*P. aeruginosa*, could explain cross transmission.

Conclusion: Unlike VIM-producing *P. aeruginosa* for which large nosocomial outbreaks have been reported in France, Greece and Italy this is the first report of a nosocomial outbreak caused by *P. aeruginosa* producing an IMP-type enzyme in France and the second description of an outbreak related to IMP-13-producing *P. aeruginosa* isolates.

P906 Metallo-β-lactamases type IMP associated with loss expression of OprD porins in nosocomial isolates of carbapenem-resistant *Pseudomonas aeruginosa*

C. Gayosso-Vazquez, D. Alcantar-Curiel, R. Morfin-Otero, E. Rodriguez-Noriega, Z. Mussaret, L. Cardiel, V. Firo, N. Justiniani, J.I. Santos, C. Alpuche-Aranda (Mexico City, Guadalajara, Merida, MX)

Background: Carbapenem resistance (CBPR) in *Pseudomonas aeruginosa* (Psa) is associated with metallo-β-lactamases (MBLs) production or AmpC activity combined with loss of the porin OprD. In addition overexpression of efflux pumps could confer CBPR. In this study we investigated molecular mechanisms of CBPR in Psa causing bloodstream infections in Mexican hospitals.
Methods: We analysed eight Psa strains characterised in our laboratory. Antimicrobial susceptibility testing was performed by disk diffusion and dilution methods following CLSI standards. MBLs activity was detected by EDTA (0.5M)-disk synergy test with MEM (10 mg) or IPM (10 mg) and by E-test-MBL. The MBL genes were characterised by PCR using specific primers for IMP, GIM, SPM and VIM, and sequencing analysis. Production of OprD porin was performed by SDS-PAGE from outer membrane proteins. PFGE and endonuclease restriction analysis was used to characterise clonal dissemination.
Results: The eight Psa strains were isolated from three different hospitals in Mexico: Hospital Civil de Guadalajara (3), Hospital OHoran, (4) and Hospital General de Mexico (1). All strains were 100% resistant to AMK, CAZ, CIP, FEP, GEN, IMP, MEM and the MIC to IMP was >256 mg/mL in 6/8 strains. MBLs activity was confirmed in all strains, however by PCR and sequencing analysis only four strains were IMP type and negative to the other types. Three of these IMP-expressing strains failed to produce OprD porin. The PFGE profile demonstrated clonal variability.
Conclusions: Although isolates analysed are few, this is the first study that confirmed multiresistance, including CBPR in Psa strains causing serious nosocomial infections selected in different geographic areas in Mexico.

P907 Molecular epidemiology of *Pseudomonas aeruginosa* producing IMP-9 type metallo-β-lactamase isolated in Guangzhou, China

C. Zhuo (Guangzhou, CN)

Objectives: To investigate the resistance mechanisms and the genetic relationship of imipenem-resistant *Pseudomonas aeruginosa* isolates recovered in some hospitals in Guangzhou.
Methods: Imipenem-resistant *P. aeruginosa* clinical isolates were collected in various wards of four hospitals from Mar 2005 to Mar 2007. The isolates were analysed by PFGE for genotype, Etest MBL, PCR and sequencing for carbapenemase-encoding genes.
Results: During the study period, 134 clinical isolates of imipenem-resistant (MIC 8 to >128 mg/L) *P. aeruginosa* were isolated, and were classified by PFGE typing into 40 clusters, based on UPGMA (unweighted pair group method with arithmetic averages) clustering method. Each hospital had its own major epidemic strains, cluster A strains was most common in Hospital A(43/66, 65.15%), and strains belonging to cluster B, C, D were isolated from Hospital B (22.6%), Hospital C(33.3%) and Hospital D (31.6%), respectively. Although there was no epidemic circulating in all 4 hospitals, cluster Q appeared both in Hospital B and D and cluster A also appeared both Hospital B and Hospital C. There was one isolate belong to independent with the same genotype found in various samples from hospital A environment survey, though six patients of lower-airway colonisation with clone A *Pseudomonas aeruginosa* had been admitted to the same ICU of hospital A for many times. Analysis of antimicrobial resistance of the epidemic strains from four hospitals, revealed that 44 of 45 cluster A isolates of *Pseudomonas aeruginosa* produced IMP-9 metallo-β-lactamase, with pI of 7.8. The bla gene located in class 1 integron, and none of cluster B, cluster C and cluster D isolates produced IMP-9 metalloenzyme.
Conclusion: The various degree of outbreak of Imipenem-resistant *Pseudomonas aeruginosa* had occurred in four hospitals individually in two years survey. Wide dissemination of IMP-9 metalloenzyme contributes partially to the imipenem resistance of *P. aeruginosa* isolates of cluster A. It was important to manger the patients colonised with epidemic strain only to prevent clonal transmission.

P908 Biochemical characterisation of the subclass B2 metallo-β-lactamase SfhI

F. Fonseca, A. Correia, J. Spencer (Aveiro, PT; Bristol, UK)

Objectives: Metallo-β-lactamases are characterised by their ability to hydrolyse almost all β-lactam antibiotics and are not inhibited by commonly used inhibitors (e.g. clavulanate, tazobactam). The β-lactamase SfhI was detected in strain *Serratia fonticola* UTAD54, an environmental isolate obtained from untreated drinking waters in the Northeast of Portugal. The aim of the present study was to purify this class B carbapenemase and determine its biochemical properties.
Methods: The blaSfhI gene was cloned into expression vector pET-26b(+) after PCR amplification using specific primers and the accuracy of the DNA construction verified by sequencing. The recombinant plasmid was transformed into *Escherichia coli* BL21(DE3). Metallo-β-lactamase SfhI was purified from induced cultures of *E. coli* BL21(DE3)(pSfhI) grown in M9Y medium supplemented with kanamycin at 25°C. Purification of SfhI was achieved by means of two chromatographic steps, anion-exchange at pH 8.5 followed by size exclusion at pH 7.0. Molecular mass and metal content of SfhI were determined by mass spectrometry. Initial hydrolysis rates for a range of β-lactam antibiotics were measured in 50 mM Hepes buffer pH 7.0 at 25°C.
Results: High level production of recombinant SfhI was achieved. Approximately 80 mg purified protein per liter of culture were obtained. By SDS-PAGE, protein was estimated to be >95% pure. On SDS-PAGE gels the purified SfhI migrates as a single band of approximately 26 kDa. Molecular mass of SfhI was determined as 26136 Da by mass spectrometry, in agreement with values predicted from the deduced amino acid sequence. The purified protein was shown to bind one equivalent of zinc, consistent with the assignment, on the basis of amino acid sequence, of SfhI to the B2 metallo-β-lactamase subgroup. Preliminary kinetic data suggest that SfhI hydrolyses penicillins, cephalosporins and carbapenems, exhibiting high affinity for carbapenems and low affinity for penicillins and third generation cephalosporins. Hydrolysis of cefoxitin and moxalactam was also detected.
Conclusion: The overexpression of blaSfhI allowed us to obtain a large amount of SfhI enzyme, enabling effective protein purification. Although the SfhI sequence is the most divergent (c.50% identity) of the known B2 metallo-β-lactamases, kinetic studies showed a substrate range that generally resembles those of other subgroup members, but includes cefoxitin and moxalactam, known inhibitors of these related enzymes.

P909 Hydrolysis parameters for doripenem, meropenem and imipenem tested with β-lactamases of molecular classes A to D

A.M. Queenan, W. Shang, K. Bush, B. Flamm (Raritan, US)

Objectives: Doripenem (DOR) is a carbapenem with activity against Gram-negative pathogens including activity against *P. aeruginosa*. One of the mechanisms of resistance observed for carbapenems such as imipenem (IPM) and meropenem (MEM) is hydrolysis by β-lactamases with carbapenemase activity. The purpose of these experiments was to determine the interactions of doripenem and comparators with β-lactamases of molecular classes A to D.
Methods: β-lactamases were purified by gel filtration and ion exchange chromatography. Protein concentrations were measured by BioRad Protein Assay. Purity of β-lactamases was assessed by PAGE gels. Initial hydrolysis rates were measured spectrophotometrically, and kinetic

parameters were determined using a Hanes plot. MIC values were determined using CLSI broth microdilution methodology.
Results: Most Class A β-lactamases, including the ESBLs TEM-26 and CTX-M-15, demonstrated very low levels of hydrolysis for DOR, IPM and MEM. However, a subset of Class A enzymes, the serine carbapenemases KPC-2 and SME-3, showed hydrolysis of all carbapenems tested. For KPC-2, DOR (kcat value 0.55 s-1) and MEM (kcat 3.6 s-1) were hydrolysed 9–60-fold slower than IPM (kcat 31 s-1). For SME-3, DOR (kcat 2.4 s-1) and MEM (kcat 3.2 s-1) hydrolysis was approximately 100-fold slower than IPM hydrolysis (kcat 320 s-1). The Class B metallo-enzymes such as VIM-2 also hydrolysed DOR more slowly than IPM (kcat 2.4 s-1 and 20 s-1). The Class C P99 and Class D OXA-10 had negligible hydrolysis of all carbapenems (kcat <0.02 s-1).
Conclusions: Doripenem was stable to hydrolysis by ESBLs and AmpC-type β-lactamases. Hydrolysis of all three carbapenems was observed with the serine carbapenemases and metallo-β-lactamases. For the carbapenemases, DOR hydrolysis was 5–100-fold slower than IPM hydrolysis.

P910 Porins and ertapenem resistance in *Klebsiella* spp. from the UK

M. Doumith, M. Ellington, D. Livermore, N. Woodford (London, UK)

Objectives: Although still rare, carbapenem resistance is increasingly detected in Enterobacteriaceae, with ertapenem often the most affected analogue. We investigated mechanism(s) of ertapenem resistance in clinical isolates of *Klebsiella* spp. referred to the UK's national reference laboratory.
Methods: MICs were determined by agar dilution or Etest. Isolates were typed by PFGE of XbaI-digested genomic DNA. Nine isolates highly resistant to ertapenem (MICs ⩾8 μg/ml) were investigated further. β-lactamase genes were identified by PCR. Phe-Arg-beta-naphthylamide (PABN) was used to test the contribution of efflux pumps. Porins were profiled by SDS-PAGE. Transcription of ompK35 and ompK36 porin genes and the acrB efflux pump gene was analysed by real-time reverse transcriptase PCR. Porin genes and their promoter regions were sequenced. Complementation analysis used a plasmid encoding OmpK36.
Results: The PFGE profiles of 30 ertapenem-resistant clinical isolates from 26 laboratories were heterogeneous. Imipenem and meropenem MICs ranged from 0.5 to 16 and from 2 to16 μg/ml, respectively. All 9 strains studied in detail produced ESBLs: CTX-M group1 (n = 3), CTX-M group1 and 9 (n = 3) and SHV (n = 3) were identified. Ertapenem MICs were reduced by ⩽2-fold in the presence of PABN, contraindicating efflux as a contributor to resistance. Isolates lacked OmpK35 and OmpK36, but there were no significant variations in the levels of expression of ompK35, ompK36 and acrB genes as compared with carbapenem-susceptible isolates. Sequencing ompK36 revealed various point mutations or insertion sequences (IS) within the Open Reading Frames (ORFs), predicted to result in early termination of translation. Sequencing of ompK35 identified a wild-type sequence for 2 isolates and an ORF disrupted by point mutation or IS10 for 2 others whereas, for 5 isolates, IS1 was identified in the promoter region or at the end of the ompK35 ORF resulting in a 10 amino acid deletion. Carbapenem MICs for all strains were reduced markedly when complemented with a plasmid carrying an intact ompK36 gene.
Conclusions: Ertapenem-resistant *Klebsiella* spp. from the UK represent diverse strains. Their major mechanism of ertapenem resistance is ESBL production in combination with porin loss, most importantly OmpK36 in conjunction with an ESBL.

P911 Characterisation of carbapenem-nonsusceptible *Escherichia coli* isolates from a university hospital in Taiwan

Y-F. Liu, J-J. Yan, W-C. Ko, S-H. Tsai, J-J. Wu (Tainan, TW)

Objectives: To investigate characteristics of carbapenem-nonsusceptible *Escherichia coli* isolates collected between 1999 and 2005 at a Taiwanese university hospital.
Methods: A total of 9 nonduplicate carbapenem-nonsusceptible *E. coli* isolates were examined. Genetic relatedness was analysed by PFGE. β-lactamases were characterised by PCR and isoelectric focusing. Outer membrane proteins and transcripts were investigated by SDS-PAGE and Northern blotting. Cloning experiments were performed to investigate the role of membrane permeability in carbapenem nonsusceptibility.
Results: The 9 carbapenem-nonsusceptible isolates were found to produce the CMY-2 AmpC enzyme (N = 8), the CTX-M-14-type extended-spectrum β-lactamase (N = 1), the SHV-12 extended-spectrum β-lactamase (N = 1), and the IMP-8-type metallo-β-lactamase (N = 1) alone or in combination. All carbapenem-nonsusceptibe isolates revealed a decrease in the transcription and protein expression of ompC, and susceptibility to carbapenems was restored in one isolate by introducing the cloned ompC gene. PFGE revealed genetic diversity among the 9 isolates. All patients with the carbapenem-nonsusceptible isolates had been treated with carbapenems (6 patients) and/or extended-spectrum cephalosporins (5 patients) before isolation.
Conclusions: Our study suggests that the decreased susceptibility to carbapenems in *E. coli* in the hospital might arise by the stepwise accumulations of multiple drug-resistance determinants in different clones.

P912 Carbapenem (cfiA) resistance gene in *Bacteroides fragilis* group strains in Belgium

I. Wybo, O. Soetens, K. Van Doorslaer, D. Piérard, S. Lauwers (Brussels, BE)

Objectives: In a recent Belgian survey [1] 3% of the *B. fragilis* group strains were not susceptible to meropenem. In our university hospital a decrease in susceptibility to meropenem was observed from 97% in 2005 to 92% and 93% in 2006 and the first 8 months of 2007 respectively. In isolates belonging to other species of the *B. fragilis* group isolates susceptibility to meropenem was 97% in 2006 and 100% in the other years. The purpose of this study was to determine the prevalence of the cfiA carbapenem resistance gene in *B. fragilis* group isolates collected for a Belgian survey for resistance in anaerobes and to look for the presence of the cfiA gene in meropenem non-susceptible strains of this group isolated in our hospital.
Methods: From October 2003 to February 2005 238 *B. fragilis* group strains (135 *B. fragilis* and 103 other species) were collected in 9 Belgian hospitals. Also included in this study were 15 meropenem non-susceptible strains isolated in our hospital. Meropenem susceptibility was determined by Etest®. The following breakpoints were used for susceptible and resistant strains: ⩽4 and ⩾16 mg/L. The strains were screened for cfiA gene by PCR with specific primers.
Results: Of 135 *B. fragilis* collected for the survey three showed reduced susceptibility (MIC=8) and three were resistant (1 with MIC=16 and 2 with MIC=32). All these isolates and three of four isolates with a MIC of 4 were cfiA gene positive. All *B. fragilis* isolates with a MIC less than 4, one *Bacteroides fragilis* isolate with a MIC of 4 and the 103 isolates from other species were cfiA gene negative.
Fifteen meropenem non-susceptible strains (MIC>4; 12 *B. fragilis*, 1 B. thetaiotaomicron, 1 B. ovatus and 1 B. vulgatis) were detected in our hospital since 2005. Eleven *B. fragilis* isolates were cfiA gene positive. The cfiA gene was not detected in the remaining *B. fragilis* strain (MIC=8) and in the other species.
Conclusion: The prevalence of the cfiA resistance gene in Belgian survey isolates (2003–2005) was 6.7% (9/135) in *Bacteroides fragilis* isolates. All except one of meropenem non-susceptible *B. fragilis* strains

isolated in our hospital since 2005 were cfiA gene positive. The cfiA gene was not detected in other species of the *B. fragilis* group.

Molecular bacteriology

P913 Characterisation of the virulence markers of Shiga toxin-producing *Escherichia coli* isolated from beef samples

M. Weiner (Pulawy, PL)

Shiga toxin-producing *Escherichia coli* (STEC) strains are an important cause of bloody diarrhoea, haemorrhagic colitis and haemolytic uremic syndrome. Transmission of STEC occurs through consumption of undercooked meat. STEC often belong to O157:H7 however, several other serogroups have been identified. The pathogenicity of STEC is mediated by Shiga toxin (Stx) and the intimin. Recent studies described additional factors: 67-kDa IrgA, Efa1, LPF or Saa.

Objectives: To characterise the virulence markers of STEC isolated from beef.

Methods: The STEC were isolated from beef samples (n = 342) by the use of DNA hybridisation with DIG probes and then tested using the multiplex PCR (rfbO157, stx1, stx2, fliCH7, eaeA, ehlyA, O26wzx, rfbO111, rfbO113 and 16SrRNA) and PCR assays (O45wzx2, O55wzx2, O121wzx1, stx2c, stx2d, stx2e, stx2f, katP, iha, toxB, efa1, saa, lpfAO157/OI-141, lpfAO157/OI-154, lpfAO113, eae alpha and gamma).

Results: Sixteen stx-positive *E. coli* strains were detected, eight were O157:H7. The stx1 marker was observed in all *E. coli* O157:H7 and in four non-O157:H7 isolates. The stx2 gene was detected in all *E. coli* O157:H7 and in seven of non-O157:H7. The identification of Stx variants resulted in presence of the stx2d gene in 13 STEC and among them 3 strains had the stx2c marker. Among eight of the O157-negative STEC, three belonged the O26 group. These isolates also carried the stx1 (one strain) or stx2 genes (two isolates). None belonged to the O45, O55, O111, O113 or O121 groups. All harboured the enterohaemolysin (ehlyA) gene whereas the intimin marker (eaeA) was observed in all *E. coli* O157:H7 (alpha) and O26 isolates (gamma). The factors such as katP, toxB and efa1 were detected in all O157:H7 as well as in one O26 isolate. Fifteen STEC were the iha-positive and five the saa-positive. None of the isolates possessing the saa marker was O157 or O26. The presence of the lpfAO157/OI-141 and lpfAO157/OI-154 genes was noted among 8 O157:H7 and in one O26 STEC. The lpfAO157/OI-141 gene was present in 4 other STEC including *E. coli* O26. None of *E. coli* O157:H7 had the lpfAO113 marker that was observed in the all remaining STEC. In one isolate belonging to the *E. coli* O26 group, for the first time a simultaneous presence of the lpfAO157/OI-141, lpfAO157/OI-154 and lpfAO113 was noted.

Conclusion: The obtained results can provide a better knowledge of the genetic diversity of STEC strains as well as should lead to great progress in molecular epidemiology.

P914 Virulence potential of extraintestinal pathogenic *Escherichia coli* strains isolated from skin, wound and soft tissue infections

M. Starcic Erjavec, Z. Petkovsek, K. Elersic, M. Gubina, D. Zgur-Bertok (Ljubljana, SI)

Objectives: The bacteria *Escherichia coli* (*E. coli*) is an important facultative anaerobe of the intestinal normal flora, but pathogenic strains can cause an impressive variety of different types of intestinal and extraintestinal diseases. Strains causing infections differ from commensal *E. coli* due to possession of virulence factors. The best characterised pathogenic *E. coli* strains are those from infections of gastrointestinal tract, urinary tract, meningitis and sepsis. Some reports of *E. coli* strains involved in skin, wound and soft tissue infections can be found, however to our knowledge no survey of the virulence potential of these strains has yet been performed. Therefore, in the presented work, a collection of 122 extraintestinal pathogenic *E. coli* strains isolated from skin, wound and soft tissue infections were studied.

Methods: Isolates were obtained from the Institute of Microbiology and Immunology, Medical Faculty in Ljubljana, Slovenia. The phylogenetic group of each strain was determined and the strains were screened by PCR with primers specific for the following virulence (related) genes cnf1(cytotoxic necrotising factor 1), hlyA (haemolysin), subA (subtilase cytotoxin), papGII (class II PapG adhesin), papGIII (class III PapG adhesin), sfaDE (S fimbriae), afa/draBC (Afa/Dr adhesins), iucD (aerobactin), kpsMT (synthesis of group II capsule), ompT (outer membrane protease) and usp (uropathogenic-specific protein). Dot-blot hybridisation experiments were performed to validate the PCR assays.

Results: Our results showed that 66% of the studied *E. coli* isolates from skin, wound and soft tissue infections belonged to group B2, 12% to the group A, 12% to the group D and 10% to the B1 group. The cnf1 gene nucleotide sequences were detected in 34% of strains, hlyA in 31%, papGII in 16%, papGIII in 23%, sfaDE in 37%, afa/draBC in 1%, iucD in 50%, kpsMT in 65%, ompT in 20% and usp in 48% of the tested isolates. No strain harboured subA sequence.

Conclusion: Our results showed that the virulence potential of *E. coli* strains from skin, wound and soft tissue infections is comparable to the virulence potential of pathogenic *E. coli* strains from other extraintestinal infections (Table 1).

P915 Cloning and expression of HpaA protein of *Helicobacter pylori*

S. Najar Peerayeh, J. Atoofi, M. Farshchian, A. Azimian, M. Razeghi, R. Samimi (Tehran, IR)

Introduction: *Helicobacter pylori* is associated with the chronic gastritis, peptic ulcer, gastric adenocarcinoma, and gastric mucosa-associated lymphoid tissue (MALT) lymphoma. The antibiotic therapies do not protect from potential re-infection, and have a risk for development of drug resistance. Therefore, the prophylactic vaccine mediated protection against *H. pylori* is an attractive clinical interest. *H. pylori* adhesin A (HpaA) is a conserved surface lipoprotein and plays important roles in pathogenesis of infection. In this study an hpaA gene cloned in pET expression vector and the recombinant protein (rHpaA) was over expressed in *E. coli*.

Methods: Genomic DNA of the standard *H. pylori* strain 26695 was isolated as the template and hpaA gene was amplified by PCR. Prokaryote expression vector pET28a inserted with hpaA gene (pET28a-hpaA) was constructed. The recombinant plasmid was used to transform competent *E. coli* DH5alpha, and positive clones were selected. Then the recombinant plasmid was used to transform *E. coli* BL21DE3 for

expression of recombinant protein HpaA. The expression of recombinant protein induced by isopropythio-beta-D-galctoside (IPTG) at different concentration was examined by SDS-PAGE. Western blot assay were used to determine immunoreactivity of rHpaA by a rabbit polyclonal antibodies against whole cell of *H. pylori*.
Results: In comparison with the reported corresponding sequences, the nucleotide sequence homology of hpaA gene was 98.8%. HpaA fusion protein was able to react with the rabbit polyclonal antibody against whole cell of *H. pylori*.
Conclusion: A prokaryotic expression system with high efficiency of *H. pylori* hpaA gene was successfully established and HpaA fusion protein showed satisfactory immunoreactivity. These results indicate that production of specific recombinant protein is an alternative and potentially more expeditious strategy for development of *H. pylori* vaccine.

P916 Characterisation of a *Streptococcus agalactiae* serotype Ia lineage with enhanced invasiveness

E.R. Martins, J. Melo-Cristino, M. Ramirez (Lisbon, PT)

Objectives: We have recently identified a lineage of group B streptococci (GBS) expressing serotype Ia as having enhanced potential to cause early-onset invasive disease in neonates (EOD). Characterisation by multilocus sequence typing (MLST) revealed that this lineage was characterised by two sequence types: ST23 and ST24. Data in the literature suggests that ST23 is not particularly virulent so we decided to further characterise this PFGE lineage regarding antibiotic susceptibility and the presence of the genes encoding the alpha and alpha-like family of surface protein, with the aim of clarifying the apparent heterogeneity within the lineage.
Methods: Susceptibility to penicillin, chloramphenicol, cefotaxime, tetracycline, vancomycin, erythromycin and clindamycin was tested by disk diffusion according to the CLSI guidelines and interpretative criteria. Macrolide-resistant isolates were further classified as having the cMLSB, iMLSB, or M phenotype by a double-disk diffusion test. A multiplex PCR reaction was set up to detect the presence of the erm(B), erm(A) and mef genes. Surface protein gene profiling was also obtained by a multiplex PCR assay targeting the bca, alp2, alp3, alp4, eps and rib genes.
Results: All isolates were fully susceptible to penicillin, chloramphenicol, cefotaxime, and vancomycin and resistant to tetracycline. Resistance to erythromycin was found in 3 isolates occurring simultaneously with clindamycin in two isolates. Of the 3 erythromycin-resistant isolates, 2 had the cMLSB and 1 the M phenotype. The isolate presenting the M phenotype carried the mef gene, whereas the erm(A) gene [erm(TR) variant] was found in the 2 cMLSB isolates. All isolates carried a single macrolide-resistance determinant. All isolates tested presented only the bca or eps genes, encoding the alpha-C and epsilon surface proteins, respectively. The bca gene was found associated exclusively with isolates representing ST24 and the eps gene only with isolates presenting ST23.
Conclusions: In spite of the mostly homogeneous susceptibility profile of the GBS lineage with enhanced potential to cause EOD, the complement of surface proteins further confirms the distinction in two sub-populations already suggested by the MLST analysis. The unusually high proportion of isolates representing ST24 and carrying the bca gene in our collection and not frequently found elsewhere, may have been decisive for the identification of the enhanced invasiveness of this lineage.

P917 Characterisation of cloning and in vitro expression of enolase from *Streptococcus suis* 2

X.Z. Pan, W. Sun, C.J. Wang, F. Zheng, J.Q. Tang (Nanjing, CN)

Objectives: To clone enolase (eno) gene and investigate some characteristic of its product Enolase (Eno) in *Streptococcus suis* serotype 2 (*S. suis* 2, SS2).
Methods: Using the Qiaexpress expression plasmids, the enolase gene was inducibly over expressed in *E. coli* to produce Enolase with a hexahistidyl N-terminus to permit its purification. Western-blot experiment and Enzyme-linked immunosorbent assay were used to detect its antigenicity. Whole cells ELISA was developed to give confirmation about Enolase localisation. Moreover, an adherence assay with Hep 2 cells was performed to determine the implication of the Enolase in the *S. suis* 2 adhesion. Action on lymphocytes designed to explore the role of Enolase in immunoreaction related to streptococcal infection.
Results: A highly homologous eno gene was unveiled by the genome-wide mining. The target DNA fragment of about 1.3 kb was successfully amplified using the genomic template of 05ZYH33 and protein expression analysis showed that a 75 kD protein can be observed in 12% SDS-PAGE, indicating that the recombinant 6His-fused Eno protein can be produced in *E. coli* under the induction of IPTG. Western-blot experiment demonstrated clearly it shares strong specific antigenicity. ELISA result suggested that Eno can occur on the surface of 05ZYH33 strain. Adherence assay showed a significant reduction in the adhesion of *S. suis* 2 in the 6His-fused Eno pre-incubated cells compared to the non-incubated cells. Evaluation of antibody titers in ELISA indicated that serum samples from pigs with SS2 infection have higher levels of antibodies that react with the recombinant Enolase than with whole bacteria sonication lysis and MRP. Apotosis of lymphocytes showed that streptococcal Enolase is a novel cross-reactive antigen that may play an important role in the initiation of the autoimmune diseases related to streptococcal infection.
Conclusion: The results exhibited the properties of Eno protein and provided an efficient Eno-based method for monitoring SS2 infection. Together, our data supported that Eno can function as a novel antigen, and may play pivotal roles in the severe infection of *S. suis* 2.

P918 Usefulness of denaturing high-pressure liquid chromatography to assess in situ gut microbiota in neonates

M.F. De La Cochetiere, G. Caillaux, F. Le Vacon, J. Caillon, J.C. Rozé, G. Potel, C. Gras-Le Guen (Nantes, FR)

Objectives: Microbiota colonisation of the neonatal gastrointestinal tract develops within a few hours after birth and major changes occur during the first postnatal weeks. Current knowledge of the gut microbial ecology is based on faeces studies, mainly by classical culture-dependent techniques. Nowadays, a new technique of fingerprinting, the DHPLC can be used. So far, however, no data is available for kinetics of implantation, growth and development of endoluminal microbiota in infants. Thus we did a prospective analysis of the in situ gut microbiota during neonatal surgery by classical cultures techniques, TTGE and DHPLC.
Methods: Newborns under 28 days of life requiring digestive surgery were included after parental information. During surgery, intestinal swabs were sampled. Then, the intestinal microbiota was analysed by conventional culture-based techniques and by two culture independent methods based upon bacteria DNA extraction and separation of amplified 16S rRNA gene fragments using Denaturing High Pressure Liquid Chromatography (DHPLC) and Temporale Temperature-Gradient Gel Electrophoresis (TTGE).
Results: 11 newborns (gestational age 33±2 weeks) were included. Two were born via caesarean section. Among the 6 newborns operated before 48 hours of life, 4 had a negative culture, no TTGE bands, three of which had a positive DHPLC analysis. The most frequent bacteria were Gram-negative bacilli (*Enterobacter* and *E. coli*), Gram-positive cocci (negative coagulase *Staphylococcus*-NCoS). Three were found with *Pseudomonas* (*P. aeruginosa*) and one with *Clostridium* (*C. butyricum*).
The three techniques used have shown coherent results. None uncultivable bacteria have been found.
Conclusion: Our work shows that DHPLC, based on DNA static analysis, is a powerful technology. DHPLC is a reproductible method that allows rapid characterisation of the bacterial establishment in neonates. DNA amplicons are easy to elute for sequencing. Moreover, it offers

full automation. The neonatal supra-mesocolic tractus is colonised very early in life mostly with Enterobacteria and NCoS.
These results could be helpful to design specific antibioprophylaxis guidelines in neonates and to monitor microbiota changes induced by various neonatal diets and treatments.
This work has been supported by Atlangene and Transgenomic

P919 Molecular evaluation of Brazilian vaginal lactobacilli microbiota and the role of hydrogen peroxide-producing isolates

R.C.R. Martinez, S.A. Franceschini, M.C. Patta, S.M. Quintana, A.C. Nunes, J.L. Moreira, K.C. Anukam, G. Reid, E.C.P. De Martinis (Ribeirão Preto, Belo Horizonte, BR; London, CA)

Objectives: To study vaginal lactobacilli populations by culture-dependent [polymerase chain reaction and amplified ribosomal DNA restriction analysis (PCR-ARDRA)] and culture-independent [PCR and denaturing gradient gel electrophoresis (PCR-DGGE)] methods, and to evaluate the ability of isolates to produce H2O2.
Methods: This study, approved by local Ethics, comprised three groups of women recruited in the city of Ribeirão Preto, São Paulo State, Brazil: 64 healthy, 68 diagnosed with vulvovaginal candidiasis (VVC) and 64 with bacterial vaginosis (BV). Samples from lateral vaginal wall were obtained with swabs, transferred to tubes containing physiological saline and decimally diluted. Dilutions were surface plated on de Man Rogosa Sharpe (MRS) agar and incubated for 48 h at 37°C (aerobiosis and anaerobiosis). Isolates characterised as Gram-positive rods, catalase and oxidase negative were identified by PCR-ARDRA and evaluated semi-quantitatively for H_2O_2 production (Merckoquant Peroxide Test; Germany). Swabs obtained from patients were also evaluated by PCR-DGGE for detection of lactobacilli.
Results: Lactobacilli were isolated from 87.5% of controls, 88.2% of subjects with VVC and 32.8% of women with BV using PCR-ARDRA, compared to 98.4%, 94.1% and 57.8% assessed by PCR-DGGE, respectively. By PCR-ARDRA, *L. crispatus* was the most prevalent isolate in control group (37.0%), followed by *L. johnsonii* (16.4%). In VVC patients' group, *L. crispatus* was also the most common isolate (35.9%) followed by *L. jensenii* (21.8%), whereas in the group of BV, *L. gasseri* (36.4%) and *L. crispatus* (18.2%) were more frequently found. According to PCR-DGGE, *L. iners* was the most prevalent species in all groups. Only *L. crispatus* was detected accordingly by both methods in the three groups (Kappa coefficient = 0.531). From healthy and VVC groups, 1.4% and 2.6% respectively of the lactobacilli isolates did not produce H_2O_2, whereas in the BV group, this rate raised to 31.8%. In both healthy and VVC groups, *L. crispatus* and *L. johnsonii* produced, comparatively, the highest average amounts of H_2O_2.
Conclusions: The evaluation o vaginal microbiota was dependent on the methodology employed and the results also suggest the absence of H_2O_2-producing lactobacilli in the vaginal microbiota may be a contributing factor for the development of BV, whereas the presence of these isolates may not be protective against VVC.

P920 The occurrence of intestinal spirochaetosis in comparison with infections due to other enteropathogenic agents in a selected group of patients

A. Calderaro, S. Peruzzi, C. Gorrini, G. Piccolo, G. Dettori, C. Chezzi (Parma, IT)

Objectives: Intestinal Spirochaetosis (IS) is a human large bowel infection due to Brachyspira aalborgi and B. pilosicoli associated with abdominal complaints (diarrhoea, pain, weight loss).
The prevalence of IS in the general population in comparison with other gastrointestinal infections was poorly investigated till now.
In our laboratory, we studied the occurrence of IS in a selected population with gastrointestinal complaints and/or potential risk factors for IS (immigration/travels from/through developing countries, HIV infection, male homosexuality) and compared the results with the occurrence of gastrointestinal infections due to viruses, bacteria other than spirochaetes and parasites.
Methods: In the period 2002–2007, clinical samples belonging to 269 patients with gastrointestinal disorders were subjected to microbiological and virological investigations in our laboratory to search for enteropathogenic agents: from 258 patients we received faecal samples, from 9 patients both faecal samples and colonic biopsies, and from 2 only colonic biopsies.
The research of intestinal spirochaetes was performed by a 16S rDNA Restriction Fragment Length Polymorphism-Polymerase Chain Reaction (RFLP-PCR) assay and PCR-positive samples were inoculated in a selective blood agar medium with spectinomycin and rifampin.
Enteropathogenic agents other than spirochaetes were searched according to standard procedures by conventional (microscopy and culture) and molecular methods.
Results: In 5 years 19 cases of IS (7%) were diagnosed by RFLP-PCR: 11 by B. aalborgi, 6 by B. pilosicoli and 2 mixed infections by both species. Ten of these patients were also infected by enteropathogenic agents other than spirochaetes.
The other patients were infected by intestinal parasites only (17.1%), gastroenteric viruses only (3.7%) or bacteria other than spirochaetes only (5.9%) whilst in a relevant group of individuals (66.1%) no enteropathogenic agents were detected.
Conclusions: Even if it refers to a selected population presenting gastrointestinal symptoms and risk factors for faecal-oral infections, the prevalence of IS reported in this study (7%) is of interest: in fact, our data suggest that IS may be more frequent than suspected in comparison with other gastrointestinal infections.
Therefore, we are confident that physicians should take IS into account when subjects with chronic abdominal discomfort present to their attention.

P921 Whole genome pyrosequencing of the epidemic multidrug-resistant *Acinetobacter baumannii* European clone II

M. Iacono, L. Villa, D. Fortini, R. Bordoni, F. Imperi, R. Bonnal, T. Sicheritz-Ponten, G. De Bellis, P. Visca, A. Cassone, A. Carattoli (Segrate, MIlan, Rome, IT; Lyngby, DK)

Objectives: the whole genomic DNA sequence was determined for an epidemic *Acinetobacter baumannii* strain (ACICU), belonging to the European clone II and carrying the plasmid-mediated blaOXA58 gene, implicated in carbapenem resistance. We compared the ACICU genome with that of *A. baumannii* ATCC 17978 and of *Acinetobacter baylyi* ADP-1, with the aim of identifying novel traits related to virulence, drug resistance and pathogenesis.
Methods: the genome was sequenced by high-density pyrosequencing and characterised for both genes coding and non coding. The genome was also analysed for lateral gene transfer.
Results: *A. baumannii* ACICU strain contains a single circular cromosome of 3,904,116 bp and two plasmids (ACICUp1 and ACICUp2) of 28,279 and 64,366 bp, respectively; the chromosome contains 3,758 genes. (3,670 CDSs, 64 tRNA genes 8 rRNA operons).
Genome comparison showed 86.4% of syntheny versus the reference *A. baumannii* ATCC 17978 strain and 14.81% versus *A. baylyi* ADP-1.
36 putative alien islands (pAs) are detected in the ACICU genome: 24 of them were previously described in the ATCC 17978 genome, 4 identified by the lateral gene transfer analysis in both ATCC and ACICU and 8 completely new, being absent in the ATCC 17978 genome
21 putative TonB-dependent outer membrane receptors were found in the ACICU genome, likely involved in iron uptake. ACICU has a conspicuous number of transporters belonging to different superfamilies, the number of which for unit length of genome (76.2) is much higher than that of ATCC 17978 (57.2) and ADP-1 (62.5), and similar to values reported for some pseudomonads.
Moreover, an antibiotic resistant island, AbaR2, was identified but it is shorter than the AbaR1 previously described in the multiresistant *A. baumannii* AYE strain.

Conclusion: the pathogenicity of *A. baumannii* is poorly understood and this organism is commonly regarded as a low-virulence bacterium, in spite of the severity of infections it causes. pAs in ACICU genome are partly divergent from those described in ATCC 17978, by acquisition of several interesting genes encoding membrane transporters, drug resistance and virulence trait for invasion and adherence. Four clusters of acquired genes were identified associated to putative phages. Since phage-related pathogenicity islands have been identified in the genome of important pathogens, the presence of unknown sequences poses the question of whether they could be involved in pathogenicity.

P922 Draft genome sequencing of two *Enterococcus faecium* strains by pyrosequencing technology reveals niche-specific gene acquisition

W. van Schaik, M.J.M. Bonten, R.J.L. Willems (Utrecht, NL)

Objectives: *Enterococcus faecium* has recently become an important cause of nosocomial infections. The rapid rise in *E. faecium* infections can be explained by the acquisition of antibiotic resistance mechanisms combined with the evolution of a hospital-associated *E. faecium* clade, termed Clonal Complex 17 (CC17). To reveal the genetic diversity in *E. faecium* strains from different environmental niches, we sequenced the genomes of two *E. faecium* strains from different clonal complexes (CC22 and CC17, respectively) using pyrosequencing technology.
Methods: The strains studied were E1071 (CC22, a vancomycin-resistant isolate that was picked up during routine hospital surveillance) and E1162 (CC17, a vancomycin-sensitive bloodstream isolate). The genomes of these two *E. faecium* strains were sequenced by Keygene (Wageningen, The Netherlands) using the GS FLX sequencer (454 Life Sciences, Branford CT, USA), with 20-fold coverage of the genome. Sequences were assembled using Newbler Assembler (454 Life Sciences). The draft genomes were annotated using the TIGR Annotation Engine and the encoded proteins were compared using PROMPT (Protein Mapping and Comparison Tool; http://webclu.bio.wzw.tum.de/prompt).
Results: The total number of sequence that could be assembled into contigs was 2.7 Mb for both strains, suggesting all but complete coverage of the genome. Automated and manually curated annotation of the draft genome sequences resulted in the prediction of 2716 and 2697 proteins for E1071 and E1162, respectively. More than 2200 proteins were more than 95% identical on the amino acid level between the two strains. Approximately 10% of the proteins were unique to each strain.
Using PROMPT the predicted proteins from the genomes of these two strains and the publicly available *E. faecium* DO strain (CC17) were compared. This revealed that the CC17 strains had genomic islands with functions in sugar uptake and metabolism that were absent in E1071. Two (partial) prophages were also specific for the CC17 strains. The presence of the TcrB copper resistance system and a specific point mutation in the vanX gene in strain E1071 strongly suggest that this strain originates from pigs.
Conclusion: Rapid draft genome sequencing has revealed the acquisition of several niche-specific genes in *E. faecium* and identified several genes and genetic elements that may be unique for CC17. The genome sequences contribute to ongoing functional studies into *E. faecium* in our laboratory.

P923 Identification of a novel genomic island specific for *Enterococcus faecium* CC17 by using the deltarho-Web model

E. Heikens, H.L. Leavis, W. van Schaik, M.J.M. Bonten, R.J.L. Willems (Utrecht, NL)

Objectives: Most hospital outbreak and invasive *Enterococcus faecium* belong to a single clonal lineage, complex 17 (CC17). We hypothesise that acquisition of genes, involved in antibiotic resistance, metabolic pathways, and virulence, contributes to the ecological success of CC17. So far, antibiotic resistance genes and the enterococcal surface protein gene, esp, which is contained on a putative pathogenicity island and plays an important role in biofilm formation, are documented CC17-specific determinants. To identify more genes, which contribute to the success of CC17, we used the deltarho-Web model (http://deltarho.amc.uva.nl). This model analyses the dinucleotide composition of a complete genome, which allows the identification of horizontally transferred genes, recognised by their anomalous dinucleotide frequency (DF).
Methods: A complete genome sequence was designed from the only sequenced strain, *E. faecium* DO, a CC17 isolate. Because this strain is sequenced partially and the order of the contigs is not known, we created a so-called complete genome sequence by randomly concatenating all contigs larger than 2022 bp, which was submitted to the model. PCR and dot blot hybridisation (DBH) were performed to determine presence and absence of genes located in regions with anomalous DF in 41 CC17 isolates and 95 non-CC17 isolates. Expression of CC17 specific genes at mRNA level was determined by RT-PCR.
Results: The model identified 5 regions with anomalous DF. PCR and DBH showed that 1 of these regions is CC17 specific and consist of a genomic island (GI) of 8 genes. Forty of the 41 CC17 isolates (97.56%) harbour this GI and only 5 of the 95 non-CC17 isolates (5.26%). The GI genes putatively encode 2 sugar transporters, 2 glycosyl hydrolases, an extracellular sugar binding protein, 2 proteins with unknown function, and a transcriptional regulator. At both sides of the GI inverted and direct repeats were found and one end is flanked by an integrase gene, indicating horizontal transfer. RT-PCR showed expression of all 8 genes.
Conclusion: By using the deltarho-Web model, a GI specific for CC17 was found. This illustrates that detection of anomalous DF using this model is a good approach for identifying acquired genes in *E. faecium*. We hypothesise that ST-17, the presumed founder of CC17, acquired this GI, tentatively encoding a novel metabolic pathway, as an adaptive mechanism providing CC17 a selective advantage in hospitalised patients.

P924 Presence of pRI1; a small cryptic mobilisable plasmid isolated from *Enterococcus faecium* of human and animal origin

L. Garcia Migura, H. Hasman, L.B. Jensen (Copenhagen, DK)

Objectives: This study focused on the molecular characterisation of a small cryptic mobilizable plasmid (6038 bp) sequenced from an *E. faecium* 9631160–1 of poultry origin. Presence of the pRI1 replication initiation gene (rep) was analysed in a panel of *E. faecium* isolates from human and animal origin in different European countries.
Methods: A plasmid replicon was cloned in vector pVA891. The insert was sequenced and primers were designed to complete the entire DNA molecule. 159 isolates were screened by PCR for the presence of the pRI1 rep. Of those, 40 were vancomycin resistant *E. faecium* (VREF) of broiler origin from the UK, 92 were of animal origin (broiler=41, pig=51) from Denmark (DK) and 27 were VREF isolated from hospitalised patients, 7 from Germany (DE) and 20 belonging to the CC17 and collected across Europe. Transfer of the pRI1 was assessed by selecting transconjugants in media with vancomycin or streptogramin.
Results: Sequence analysis of pRI1 revealed 8 open reading frames. Based on sequence similarity at DNA and protein level, pRI1 contained a rep highly identical to the repA from the pEFNP1 plasmid from *E. faecium* N15. A mob gene was also identified whose putative function could be the mobilisation of the plasmid. pRI1 harboured a cluster of 4 coding sequences (CDS). CDS1 translated into a truncated EfaeDRAFT_2604. CDS2, CDS3 and CDS4 coded for 3 hypothetical proteins, EfaeDRAFT_2603, EfaeDRAFT_2602 and EfaeDRAFT_2601 respectively. The 4 CDS exhibited 100% homology to those described in contig658 (from nt 8940 to 10196) of *E. faecium* DO. In addition, an IS with 100% homology to ISEfa4 described in a vanD-type VREF 10/96A was also identified. Of 159 isolates tested for presence of pRI1 rep, 60 produced an amplicon. Of those, 27/40 were from UK, 22/41 and 2/51 of broiler and pig origin from DK, 5/7 from DE and 4/20 belonged to the CC17. Conjugation experiments verified transfer of the pRI1 together with conjugative plasmids harbouring resistances to vancomycin and streptogramin.
Conclusions: The genetic composition of pRI1 illustrates the plasticity of the enterococcal plasmids and the "mosaic" arrangements of the

different genes assembled into one mobile genetic element (MGE). The presence of pRI1 in enterococcal isolates geographically separated and from different origin demonstrates the ability of enterococci to acquire and transfer MGE, emphasising the need for further studies to reveal the meaning and role that they play in nature.

Current methods for typing MRSA and MSSA

P925 Comparison of the DiversiLab System and pulsed-field gel electrophoresis for typing meticillin-resistant *Staphylococcus aureus* isolates

F. Tenover, E. Gay, S. Frye, S. Eells, M. Healy, J. McGowan, Jr. (Atlanta, Athens, US)

Objectives: Typing of meticillin-resistant *Staphylococcus aureus* (MRSA) isolates is difficult for clinical microbiology laboratories to perform. Pulsed-field gel electrophoresis (PFGE) is time consuming and often difficult to interpret for inexperienced users. Thus, we examined the ability of the Bacterial Barcodes DiversiLab system (DL) to distinguish among USA PFGE types and to correctly differentiate outbreak-related MRSA from sporadic isolates collected from several U.S. hospitals.
Methods: 105 isolates of MRSA of PFGE types USA100–1100 (plus the Brazilian clone) from the ICARE and CDC strain collections were typed using the DL system. DL strain relatedness was defined as a minimum of >95% similarity with up to 1 band difference. USA types were defined using >80% similarity. In addition, 4 unique sets consisting of 6 MRSA isolates each (where 5 isolates were indistinguishable by DL and 1 was an unrelated DL type), each from separate outbreaks in 3 U.S. hospitals, were typed by PFGE. Tenover criteria were used for PFGE outbreak analysis.
Results: DL separated the 105 MRSA isolates of known USA types into 13 clusters and 6 singletons. DL grouped USA100, 200, 600, and 1100 isolates into unique clusters. Multi-locus Sequence Type 8 isolates (USA300, 500 and Brazilian clone) often clustered together at >95% similarity in the DL dendrogram, although USA300 and 500 DL patterns showed a consistent 1 band difference. USA400 and 700 isolates also clustered together but had distinguishable DL patterns. Among the hospital outbreak clusters, PFGE and DL both identified the same "unrelated" organism in all 4 sets; however, PFGE showed more pattern diversity than did DL.
Conclusion: DL is less discriminatory than PFGE, although it tends to cluster isolates of the same USA type together. DL can be used to identify USA types only by direct comparison of DL patterns with a known USA type strain. Although the DL patterns of the outbreak strains were indistinguishable, the PFGE patterns of 3 of 4 sets reflected greater pattern diversity. Thus, DL is useful for screening for potential outbreaks of MRSA, but additional typing may be necessary to confirm strain relatedness and specific USA types.

P926 Comparison of an automated repetitive sequence-based PCR typing technique to pulsed-field gelelectrophoresis and multi-locus sequence typing for characterisation of epidemic meticillin-resistant *Staphylococcus aureus* strains

W.B. van Leeuwen (Rotterdam, NL)

Objective: the DiversiLab™ system, which employs repetitive sequence-based PCR (rep-PCR) to genetically characterise microorganisms (prokaryotes and eukaryotes), was evealuated as a molecular typing tool for meticillin-resistant *Staphylococcus aureus* (MRSA) strains.
Methods: we have analysed a representative selection of the HARMONY collection, composed of MRSA strains (n = 33) from 11 European countries. DiversiLab results were compared to those assessed by pulsed-field gelelectrophoresis (PFGE) and clonal designations based on multilocus sequence typing (MLST).
Results: the level of discrimination was determined by application of Simpson's index of diversity, resulting in indices of 90.5%, 87.7% and 86.0% for PFGE, MLST and rep-PCR respectively. A high level of concordance in classification of the MRSA strains was obtained using each method. MLST and rep-PCR distinguished 15 and 17 genetically related groups, as PFGE differentiated the collection into 28 pulsetypes.
Conclusion: compared to both other typing techniques, the performance of the DiversiLab is good with respect to labour intensity and rapidity. This system may be useful for long-term epidemiological studies, but lack the discrimination needed for outbreak analysis.

P927 Epidemiological typing of meticillin-resistant *Staphylococcus aureus* strains by FT-IR

R. Guiomar, O. Preisner, Z. Videira, J.A. Lopes, J.C. Menezes, J. Machado (Lisbon, Oporto, PT)

Meticillin-resistant *Staphylococcus aureus* (MRSA) is widely known as the most significant nosocomial pathogen due to the burden of disease it causes, as well as to the evolution and global spread of multidrug-resistant clones.
Objective: The goal of the present study is to evaluate the Fourier transform infrared (FTIR) spectroscopy as a rapid, accurate and cost-effective method to characterise and discriminate between MRSA strains responsible for nosocomial infections.
Methods: MRSA strains were studied by Pulse Field Gel Electrophorese (PFGE – enzyme SmaI) and rep-PCR, two molecular methodologies that provide the genomic fingerprint with high discriminatory power. Although time consuming and labour intensive PFGE is accepted as the gold standard for molecular typing. MRSA strains were also studied by FTIR assess the overall molecular composition of microbial cells in a non destructive manner, giving the "whole organism fingerprinting". The collected spectral data were analysed using a wide range of chemometrics techniques to discriminate closely related strains.
Results: MRSA were separated in distinct clones by PFGE, rep-PCR and FTIR. Analysis of SmaI macrorestriction profiles of the MRSA clinical isolates revealed five major clusters. The rep-PCR allowed grouping strains within various degrees of genotypic relatedness leading to the identification of bacterial clones. All the strains were evaluated by FTIR spectroscopy as well. Different pre-processing methods were analysed in order to reduce spectral variability. Unsupervised and supervised classification methods were employed to cluster the different MRSA clones based on similarity of their FTIR spectra. Our results demonstrated concordance with PFGE and rep-PCR methods.
Conclusion: FTIR spectroscopy is a promising tool for epidemiological typing of MRSA, providing quantitative information about the total biochemical composition of the intact cell reflected in the infrared spectra. FTIR is a simple, non-destructive, without use of any reagent and rapid to perform thus has the potential for an alternative method for MRSA epidemiological typing. In case of nosocomial outbreak FTIR enables a fast identification of MRSA clones responsible for hospital infection and a rapid implementation of controlling measures leading to a decreasing of new cases of nosocomial infection due to the same bacterial clone, saving suffering and money.

P928 Spa typing is an excellent method for surveillance of MRSA

S. Melin, S. Lofgren, A. Matussek (Jonkoping, SE)

Objectives: Pulsed-field gel electrophoresis (PFGE) is considered gold standard for typing of *Staphylococcus aureus*, but the method is afflicted with problems. Simple objective molecular methods, like spa typing, can therefore considerably simplify epidemiological studies of *S. aureus*. In this study we compare spa typing to PFGE, related to epidemiological data in a low endemic setting, and show that spa typing is an excellent method for surveillance of transient outbreaks of meticillin-resistant *S. aureus* (MRSA).
Methods: All of the MRSA (n = 304) isolated in the county of Jonkoping from January 2003 through July 2006 were analysed by spa typing and PFGE. In addition, Panton-Valentine leukocidin (PVL) toxin presence

was investigated using a PCR based method. Epidemiological data was collected and 12 outbreaks were identified, including 68 isolates.

Results: We identified 24 different spa types and 28 different PFGE patterns in 20 PFGE types. Isolates within three of 12 outbreaks exhibited several related but distinguishable PFGE patterns. In seven of the outbreaks all of the isolates were of a single PFGE type (SE97–3). All of the isolates within an outbreak were of the same spa type. Three outbreaks contained isolates of spa type t015 of which all belonged to PFGE type SE97–3 and two outbreaks consisted of isolates of spa type t008.

Isolates carrying the PVL toxin gene, occurring in outbreaks, were all community-associated (Table 1).

Table 1: Description of the MRSA outbreaks in the county of Jönköping, 2003–2006

Outbreak	Number and association in outbreaks	*spa* type	PFGE pattern	PVL
1	2, neighbours	t202	SE03-9	+
2	3, family	t015	SE97-3f	–
3	8, associated to retirement home	t630	SE97-3, -3t, -3v	–
4	11, associated to retirement home	t008	SE00–11a, -11d	–
5	12, associated to retirement home	t050	SE97-3af, -3, -3d	–
6	3, hospital	t015	SE97-3	–
7	2, family	t008	SE00-7d	+
8	15, associated to retirement home	t669	SE97-3af	–
9	3, associated to retirement home	t223	SE04-4a	–
10	3, hospital	t993	SE97-3f	–
11	3, family	t015	SE97-3a	–
12	3, family	t1096	SE01-3	+

Conclusion: All isolates within an epidemiological well characterised outbreak were of the same spa type, revealing better concordance to epidemiological data than PFGE as three outbreaks included isolates of PFGE patterns with minor differences, splitting well defined outbreaks into more than one. Furthermore spa typing is superior to PFGE in routine microbiological laboratories due to its objectivity, short turn-over time, ease of use, and possibility of interlaboratory comparability. spa typing must therefore be considered a very useful method for epidemiological investigations of MRSA in low prevalence areas.

P929 Molecular characterisation of *Staphylococcus aureus* dialysis associated bacteraemia isolates. Developing microarray analysis towards future rapid typing applications

M. Stone, J. Wain, A. Ivens, T. Feltwell, A. Kearns, M. Jones, K.B. Bamford (London, Cambridge, UK)

Objectives: *Staphylococcus aureus* is an important pathogen in healthcare associated infection. Within the haemodialysis setting it is responsible for high levels of morbidity and mortality and associated with access related bacteraemia. A particular problem with in any healthcare setting is defining preventable transmission and recurrence of clinical infection. To aid this definition we need timely locally applicable typing systems that are technically and financially suitable for everyday use. Our objective was to use well characterised isolates from the dialysis associated bacteraemia setting as a platform towards developing a clinically relevant rapid typing system which would eventually be of use within a routine diagnostic laboratory.

Methods: Thirty-nine consecutive clinically relevant renal *S. aureus* bacteraemia isolates collected between July 2002 and March 2003 were characterised by antibiogram, phage typing, pulsed-field gel electrophoresis (PFGE) and multi-locus sequence typing (MLST). Meticillin resistance was detected in 46% of isolates and defined by phenotypic and molecular methods. A defined representative subset of isolates were characterised using a staphylococcal microarray. The combined approach was analysed using Bionumeric software.

Results: Phage typing followed by PFGE revealed eight patterns, clustering into 2 major types, EMRSA-15 and EMRSA-16. MLST showed that the MRSA isolates belong to ST22 and ST36. Isolates that were identical by MLST had either identical or similar PFGE fragment patterns. Microarray analysis allowed the definition of 'core' and 'accessory' genomes and the identification of potential amplification targets for use in a relevant and rapid typing scheme. Accessory genes were defined by approximately 23% of 4016 staphylococcal features on the array and is supported by current literature in this area. Bionumeric software is displays the level of congruence between PFGE and microarray analysis.

Conclusion: EMRSA-15 and 16 were identified as major groups within which to define future subtyping targets. Suitable gene targets for discrimination are identified and can be defined and developed in this way. This is a realistic approach towards developing novel technology based typing systems that could be used in future diagnostic settings.

P930 Investigation of epidemiological links between patients harbouring identical, non-predominant MRSA genotypes as defined by double-locus sequence typing

L. Senn, G. Zanetti, F. Bally, C. Chuard, A. Cometta, M.C. Eisenring, G. Kuhn, D.S. Blanc (Lausanne, Sion, Fribourg, Yverdon, CH)

Background: Molecular epidemiology postulates that 2 isolates belong to the same chain of transmission if they are similar according to a highly discriminatory molecular typing method. This has been demonstrated in outbreaks, but was never studied in endemic situations. Epidemiological links cannot be established between isolates of meticillin-resistant *Staphylococcus aureus* (MRSA) that belong to endemic predominant genotypes. In contrast, small clusters of identical genotypes, some of which are subtypes of predominant genotypes, could be studied for epidemiological tracking.

Objective: To investigate epidemiological links between patients harbouring MRSA genotypes that belong to non-predominant typing clusters at a regional level.

Methods: We recently showed that double-locus sequence typing (DLST), a new typing strategy for MRSA that uses the repeat sequences of clfB and spa genes, was reproducible and discriminant enough to make this method a candidate of choice for epidemiological analyses. Our laboratory centralises the majority of the MRSA isolates from Western Switzerland. All nonrepetitive isolates received between 2005 and 2006 were typed by DLST.

Results: 1658 MRSA isolates were typed. 1118 (67%) belonged to 4 predominant genotypes, 216 (13%) to 54 small clusters of 2–12 patients, and 324 (20%) were unique. Strong epidemiological links (simultaneous hospitalisation in the same ward/hospital/long term care facility, or member of the same family) were found in 22/54 (41%) small clusters of non-predominant genotypes, totalising 60/216 patients (28%). In addition, weaker epidemiological links (hospitalisation during the same year in the same ward/hospital/long term care facility, or same place of residence) were found in 41/216 patients (19%). In the remaining 115/216 (53%) patients harbouring identical non-predominant genotypes, no epidemiological link could be detected.

Discussion: In our setting of patients harbouring non-predominant MRSA genotypes, epidemiological data could not explain the chain of transmission behind all isolates of the same genotype. One hypothesis is that our surveillance system was not able to detect the missing links. Another hypothesis is that some genotypes are stable over time, so that, as for predominant genotypes, epidemiological links can no longer be found.

Conclusions: Epidemiological tracking of MRSA isolates at a regional level cannot be inferred from molecular typing alone.

P931 Double locus sequence typing: a high through-put molecular typing method for meticillin-resistant *Staphylococcus aureus*

G. Kuhn, G. Zanetti, P. Francioli, D.S. Blanc (Lausanne, CH)

Background: Molecular typing is required for the surveillance of meticillin resistant *Staphylococcus aureus*. We recently showed that

DLST, a new typing strategy for MRSA was reproducible, as discriminant as PFGE and gave unambiguous results (JCM 2007, 45:54–62). Rapidity, accessibility, ease of use, cost and amenability to construct an electronic database, are other important criteria of convenience for longitudinal comparison of large numbers of isolates (CMI 13, suppl. 3; 2007).

Objective: To evaluate DLST according to convenience criteria for the surveillance of MRSA at a regional level.

Material and Methods: DLST is based on single strand sequencing of partial repeat sequences of genes clfB and spa. All procedures and reactions were adapted to function in 96 well format. Our laboratory centralised the majority of the MRSA isolates from Western Switzerland. All isolates received between 2005 and June 2007 were typed by DLST.

Results: The laboratory isolated and received 1668 isolates during the study period. Typing of one plate (96 isolates) was performed in a weeks time (including bench work, sequence analysis, and incorporation into a Bionumerics database); all isolates were processed within 18 weeks. Reinjection was necessary for 15.2% of clfB and 5.7% of spa sequencing reactions, and the DNA of 1.3% of all isolates had to be extracted again. The cost of consumables was calculated to be Euro 9.-/isolates, (versus Euro 2.40 with PFGE), and the staffing cost Euro 13.–/isolates (versus 26.– with PFGE).

Discussion: Cost efficiency was achieved by performing DLST in 96 well plates. In a weeks time, 96 isolates could be typed, whereas only 48 isolates could be typed by PFGE using a rapid protocol (JCM 1992; 30:577–80). DLST was cheaper than PFGE, and accessible to all laboratories with sequencing facilities. The low percentage of isolates from which DNA had to be extracted a second time indicated a robust protocol. Using an improved polymerase for PCR, the percentage of clfB sequence reinjection was considerably reduced. The major advantage of DLST is that genotypes can be unambiguously assigned, which allows to incorporate results in an electronics database.

Conclusions: The use of DLST proved to be a convenient method for longitudinal surveillance of MRSA genotypes at a regional level.

P932 Species identification and simultaneous detection of rifampicin resistance in staphylococci using rpoB sequencing

B. Hellmark, B. Söderquist, M. Unemo (Örebro, SE)

Objectives: In recent years, coagulase-negative staphylococci (CoNS) have been recognised as causative agents of various infections, especially in immunocompromised patients and related to implanted foreign body materials. A major problem is to distinguish clinically significant CoNS strains from those representing contamination. Therefore rapid, highly sensitive and specific methods are needed for species identification and further typing. Foreign body infections caused by CoNS are difficult to treat since CoNS have the ability to produce biofilm. β-lactams and glycopeptides lack activity against biofilm producing and stationary phase bacteria. In contrast, rifampicin has the ability to penetrate biofilm. However, resistance to rifampicin may rapidly emerge and, accordingly, monotherapy should be avoided.

The aim was to develop and evaluate a rapid and objective method, based on rpoB sequencing, for species identification and simultaneous detection of rifampicin resistance in staphylococci.

Methods: Fifty-one isolates, representing 17 different *Staphylococcus* species, were included for species identification, and isolates (n = 30) from eight patients, obtained pre- and post-treatment with rifampicin, were included for detection of rifampicin resistance.

A real-time PCR followed by sequencing was developed for a 1052 bp segment of the rpoB gene. The sequences were analysed using BioEdit software v. 7.0.5.3 and submitted to GenBank for species identification. In case of discrepancies between the initial phenotypic species identification (using ID32Staph) and rpoB sequencing, 16S rRNA gene sequencing was used.

Results: Forty-nine (96%) of the 51 isolates were possible to species identify using rpoB sequencing and the two remaining isolates were not staphylococci according to the discrepancy analysis. Comparing the results of rpoB sequencing with the phenotypic identification revealed that eight (16%) of the 49 isolates differed regarding identified species. Each isolate resistant to rifampicin from the eight patients displayed identical rpoB sequence as its corresponding rifampicin susceptible isolate except for one (in six patients) or two (n = 3) nonsynonymous single nucleotide polymorphisms (SNPs), or an insertion of one codon, which has not previously been described (n = 3).

Conclusion: Sequencing of the rpoB gene is a rapid, objective and accurate method for species identification and simultaneous detection of rifampicin resistance in staphylococci.

P933 Application of the (GTG)5-PCR fingerprinting for rapid identification of staphylococcal species occurring in humans

D. Novakova, P. Svec (Brno, CZ)

Objectives: Staphylococci are natural inhabitants of skin, glands and mucous membranes of mammals and birds and play very important role in human infections as well. Development and evaluation of effective and reliable identification tools is needed for routine and rapid identification of increasing number of *Staphylococcus* spp. occurring in human clinical material.

Method: A group of 68 type and reference staphylococcal strains representing 22 taxa of human associated staphylococci was analysed by rep-PCR fingerprinting with the (GTG)5 primer. The clinical isolates as well as strains isolated from healthy hosts and environmental samples were tested.

Results: All tested strains were typeable by the (GTG)5-PCR producing DNA fragments ranging from 200 bp to 4500 bp. Majority of the tested species revealed species-specific fingerprints, moreover *Staphylococcus capitis* ssp. *capitis*, *S. capitis* ssp. *ureolyticus* and *Staphylococcus cohnii* ssp. *cohnii* and *S. cohnii* ssp. *urealyticum* were differentiated at the subspecies level. In contrast, *Staphylococcus hominis* subspecies were not clearly distinguished. *Staphylococcus sciuri* ssp. *sciuri*, *Staphylococcus intermedius* and *Staphylococcus cohnii* ssp. *urealyticum* strains revealed two different fingerprint clusters each. The highest intraspecies similarity showed *Staphylococcus warneri* (88.95%) and *Staphylococcus auricularis* (87%) strains in this study.

Conclusion: The obtained results imply that rep-PCR fingerprinting with the (GTG)5 primer is suitable method for reliable and rapid identification of the majority of staphylococcal species occurring in humans.

The study was partly supported by the project MSM0021622416.

P934 Evaluation of MLST for *Staphylococcus aureus* typing using labelled-primers chemistry

V. Chini, E.D. Anastassiou, I. Spiliopoulou (Patras, GR)

Objective: Staphylococcal typing is important for studying nosocomial and community outbreaks, defining the relationship between isolates. Multilocus Sequence Typing (MLST) relates staphylococci on the basis of the nucleotide sequences of ~450 bp internal fragments of seven conserved housekeeping genes (arcC, aroE, glpF, gmk, pta, tpi, yqiL). For each gene fragment, the different sequences are assigned as distinct alleles at each of the seven housekeeping loci (the allelic profile or sequence type, ST). A major advantage of MLST is the ability to compare results obtained by different studies via Internet, in freely accessible databases. The purpose of the present study was the evaluation of MLST using the labeled-primers chemistry.

Methods: Five representative MRSA were selected according to their phenotypic characteristics, SCCmec and agr types, PFGE, and the presence of toxin genes. These strains were also previously characterised by MLST using the BigDye Terminator chemistry (BigDye Terminator v3.1 cycle sequencing Kit, Appliedbiosystems) and the ABI 3730 XL Capillary Sequencing (Appliedbiosystems) device. Bacterial cultures in Brain Heart Infusion broth (BHI), after overnight incubation at 37°C, were used for DNA extraction applying the phenol:chloroform method. The seven housekeeping genes were first amplified by PCR. PCR products were then purified and sequenced bi-directionally by

using labeled-primers chemistry (Cy5.5 for the forward and Cy5.0 for reverse primers) and the OpenGene DNA Sequencing System (Visible Genetics, Inc. Toronto, Ontario, Canada). PCR conditions were optimised in experiments applying gradient of primer concentrations.
Results: Optimised final concentration of primers was achieved at 0.1microM for the downstream and 0.15microM for the upstream in each reaction tube. Results from both MLST techniques concerning the allelic profiles, the Sequence Types (ST) and the Clonal Complexes (CC) agreed and no variations were detected.
Conclusion: The adaptation of MLST using the labeled-primers chemistry and vertical electrophoresis, which is for the first time reported, gave reproducible results, allowing its application in laboratories that do not possess a capillary sequencing device.

P935 Molecular characterisation of meticillin-resistant *Staphylococcus aureus* nasal isolates from patients with uncomplicated skin infections

R. Shawar, N. Scangarella, G. Li, M. Twynholm, M. Dalessandro, J. Breton, J. West, L. Miller, P. O'Hara, H. Madsen, D. Payne, R. Goering (Collegeville, US; Greenford, UK; Research Triangle Park, Omaha, US)

Objectives: In order to better understand the clonal composition and epidemiology of meticillin-resistant *Staphylococcus aureus* (MRSA) from nasal carriage, we molecularly characterised all nasal MRSA isolates recovered in 2004–2005 from patients with uncomplicated skin infections enrolled in Phase III clinical trials of retapamulin, a new topical antibiotic agent.
Methods: Nasal swab samples were obtained from patients with uncomplicated skin infections enrolled in five global phase III clinical trials. All nasal MRSA isolates were examined by pulsed-field gel electrophoresis (PFGE), multilocus sequence typing (MLST), Staphylococcal cassette chromosome (SCCmec) typing, and were tested for the presence of Panton-Valentine leukocidin (PVL) genes. Nasal MRSA isolates were recovered from patients in 7 different countries (Costa Rica, France, Germany, India, Peru, South Africa, and the United States) but the vast majority were recovered from patients in the United States.
Results: A total of 105 MRSA isolates were recovered from nasal cultures at baseline and/or at follow up visits from 62 patients. Of the 54 baseline MRSA isolates, 23 (42.6%) were determined to be PFGE type USA300, PVL-positive and contained type IV SCCmec and of those 20 were also MLST type 8. Except for one isolate recovered from a patient in Costa Rica, the vast majority (19/20;95%) were recovered from patients in the United States. The remaining 31 MRSA isolates were distributed among 4 other recognised MLST/PFGE genotypes or were not matched to any PFGE types currently in the CDC database. Of the 30 patients who had a nasal MRSA isolate recovered from more than one follow up visit, 19 (63%) had the same PFGE type at each visit.
Conclusions: This study demonstrates that PVL-positive, USA300 MRSA was carried in the anterior nares of patients with uncomplicated skin infections and was found to be the predominant type collected from the baseline nasal samples of patients in the United States. The majority of patients who had MRSA isolated from their anterior nares at two or more visits maintained carriage of the same PFGE type. Both of these findings have significant implications for epidemiologic investigations and for planning future interventional studies.

P936 Determining evolutionary lineages of *Staphylococcus aureus* using variable number tandem repeats

K. Hardy, B. Short, J. Thomas, M. Enright, P. Hawkey (Birmingham, Warwick, London, UK)

Objectives: The aim of the study was to determine the ability of variable number tandem repeat typing to define evolutionary lineages using a well characterised global collection of MSSA and MRSA isolates.
Methods: Ninety two isolates of *S. aureus* from diverse origins were included in the study. The isolates consisted of 41 MRSA (SCCmec types I to IV) and 51 MSSA isolates, as well as examples of isolates from the five major global clonal complexes. All isolates were typed using three sequence based typing methods, MLST, spa and sas typing and using 7 previously described variable number tandem repeats termed staphylococcal interspersed repeat units (SIRU). The numbers of repeats at each locus were determined and a 7 digit profile generated. All of the epidemiological typing data was analysed using Bionumerics and SIRU data analysed using Euclidian coefficient. Simpson's index of diversity was used to calculate the index of discrimination of all the typing techniques.
Results: All isolates were typeable by all four typing methods, and gave 100% reproducibility. SIRU typing provided the greatest level of discrimination (D=0.997 CI 0.995, 1.000), significantly greater ($P<0.05$) than that provided by the most discriminatory sequence based method, spa typing (D=0.9847, CI 0.975 to 0.994). Both spa and sas typing gave a higher index of discrimination than MLST (0.965 versus 0.939 respectively).
Cluster analysis of the SIRU profiles demonstrated concordance with the MLST data, whilst providing a greater degree of diversity. Isolates that are diverse by MLST (greater than two loci different) were not clustered together by SIRU. SIRU typing arranged the isolates into five main groups, clustering together isolates from CC30, CC22, CC1, and CC5 into distinct complexes, while the majority of isolates from CC8 were clustered together. Singleton strains, those unrelated to the major clonal complexes, were diversely spread.
Conclusion: This study uses isolates that have been previously used to define the evolution of MRSA and clustering analysis demonstrates that SIRU has excellent concordance with previously used sequence based typing methods. SIRU provides a greater degree of discrimination than MLST allowing a more detailed insight into the evolution of individual clonal complexes, whilst still retaining the overall population structure exhibited in the clonal complexes defined by MLST.

P937 Variable number tandem repeat assay for typing meticillin-resistant *Staphylococcus aureus*

B. Rivero-Pérez, E. Pérez-Roth, J. Alcoba-Flórez, F. Laich, A. Espinoza-Jiménez, S. Méndez-Álvarez (Santa Cruz de Tenerife, ES)

In the work with pathogen microorganisms, the knowledge of their DNA fingerprints is necessary for the delineation of outbreaks of infections disease and for the global tracking of them. For these reasons, on the last decades an intense search of methods to improve this way has taken place. Variable Number Tandem Repeat Assay (MLVA) was described for the first time in 1995 as a new typing method for *Haemophilus influenzae*. Later, in 2003 Sabat et al. introduced it for the study of *Staphylococcus aureus*. However, the usefulness of this technique is still an opened question.
Objectives: The aim of our study has been to determine the utility of MLVA for typing *S. aureus* isolates and to compare the results obtained with those generated by means of the Pulsed-Field Gel Electrophoresis (PFGE).
Methods: A multiplex PCR assay, optimised by us, containing primers to simultaneously amplify clfA, clfB, sdrCDE, spa and sspa loci, and PFGE macrorrestriction patterns analysis were applied to a group of meticillin-resistant *S. aureus* (MRSA), collected since 2002 to 2006. The results obtained by both approaches were compared by means of the power of discrimination of each of them.
Results: All MRSA isolates were typeable by MLVA, being grouped in 23 types, according to the criteria established by Sabat et al. (2003), whereas the PFGE assay distinguished 17 types according to the criteria established by Tennover et al. (1995). As a general rule, within each pulsed-field type, a majority MLVA pattern and others that had one band change with this were noticed.
Conclusion: MLVA is a reliable technique, with a high power to discriminate MRSA isolates. This capacity can be used to perform a local characterisation of MRSA collections. MLVA patterns seem to belong with PFGE types, whenever we consider subtypes (one band different of the majority pattern) inside MLVA types.

Diagnostic serology

P938 Multicentre evaluation of the Toxo IgG assay on the Family of Access® immunoassay systems from Beckman Coulter

P. Flori, D. Uettwiller-Geiger, O. Flecheux, R. Tran Manh Sung, C. Darte, F. Bouniort, M. Olson (Saint-Priest-En-Jarez, FR; Port Jefferson, US; Marnes-la-Coquette, Marseille, FR; Nyon, CH; Chaska, US)

Background: *Toxoplasma gondii* is a protozoan capable of infecting many species of mammals and birds. Human infection is common worldwide, although prevalence varies with subject age and geographic location. Infections in adults and children past the neonatal stage is usually unapparent. Primary infection acquired just before and during pregnancy may lead to fetal death or serious congenital abnormalities. Serological confirmation of antibodies to *Toxoplasma* is indicative of exposure to the parasite and is the principal means of diagnosis and follow-up.
The Access® Toxo IgG assay is based on paramagnetic particle, solid phase technology and chemiluminescent signal detection. The Access Toxo IgG assay has been restandardised to the WHO 3rd international standard TOXM.
Objectives and Methodology: Access Toxo IgG assay reproducibility was evaluated at three centres. Reproducibility was determined with nine samples with varying degrees of reactivity and two controls, analysing five replicates of each sample for seven days. Concordance (percent agreement) with the Abbott AxSYM assay was evaluated at two sites. Two hundred and seventy nine de-identified residual samples from pregnant subjects were tested as well as four hundred and seventy one non-selected samples from male and female subjects who had Toxo IgG testing ordered. The platform utilised at all centres was the Access 2 Immunoassay System. Similar performance has been demonstrated on the UniCel® DxI 800 Access Immunoassay System.
Results: At the cut-off (10.5 IU/mL) within site total CV% ranged from 8% to 10%. The overall agreement of the Access Toxo IgG assay to the AxSYM Toxo IgG assay was 97.3% (95% CI, 95.9% to 98.4%). The relative sensitivity was 98.0% (95.9% to 99.2%) and the relative specificity was 99.5% (98.1% to 99.9%).
Conclusion: The Access Toxo IgG assay provides excellent concordance to the comparison method to aid in the diagnosis of *Toxoplasma gondii* infection and the determination of protective levels of antibodies in pregnant women and the general population with the advantage of a rapid, automated random-access immunoassay system.

P939 Analytical performances of the new Access® Toxo IgG assay

F. Bouniort, O. Flecheux, A. Clement, C. Stoia, F. Margotteau, D. Duhamel, J. Poropane, R. Falcou, C. Walton (Nyon, CH; Marnes-la-Coquette, FR; Chaska, US)

Objectives: In order to be aligned with international standardisation recommendations, Beckman Coulter has restandardised the Access® Toxo IgG assay to the WHO 3rd International Standard (TOXM). The purpose of this study was to evaluate the analytical sensitivity including limit of blank (LoB), limit of detection (LoD), limit of quantification (LoQ), as well as linearity, precision and analytical specificity of the new Access Toxo IgG assay.
Methods: The analytical sensitivity was determined according to the CLSI EP17-A procedure. LoB and LoD were defined with four negative and low level samples tested 60 times. LoQ, determined with samples with known expected *Toxoplasma* IgG concentration, was determined over five days with one run/day and five replicates per run. Linearity was studied with *Toxoplasma* IgG high positive samples diluted from 1:1.5 to 1:32. The precision studies used negative, low, medium and high positive samples and included intra- and interassay determinations or studies as well as inter-lot studies. Analytical specificity was determined by testing 310 samples obtained from patients with specific disease conditions.
Results: The Access Toxo IgG assay displays a LoB, LoD and LoQ of 0.10 IU/mL, 0.40 IU/mL and 3.2 IU/mL, respectively. The linear regression slope for linearity study was 1.07 with a total mean recovery percentage of 99.9%. The precision studies demonstrated a CV below 6%, 11% and 11% for intra-assay, inter-assay and inter-lot, respectively. Among the 310 samples tested for the analytical specificity, 303 were found negative with the new Access Toxo IgG assay.
Conclusion: The new Access Toxo IgG assay provides excellent performance, with the advantages of a rapid, automated random access immunoassay system.

P940 Comparative studies of the new Access® Toxo IgG assay

F. Bouniort, O. Flecheux, A. Clement, C. Stoia, F. Margotteau, D. Duhamel, J. Poropane, R. Falcou, C. Walton (Nyon, CH; Marnes-la-Coquette, FR; Chaska, US)

Objectives: A new quantitative Access Toxo IgG assay, restandardised by Beckman Coulter to the WHO 3rd International Standard (TOXM), was studied in order to determine concordance between the new assay and the AxSYM** Toxo IgG assay. Relative specificity and sensitivity were calculated within the tested populations as compared to a reference method.
Methods: The concordance studies were performed with samples from non-selected blood donors (n = 700), non-selected hospitalised patients (n = 3824) and non-selected pregnant women (n = 358). The comparative device used for these studies was the Abbott AxSYM Toxo IgG assay and a percentage of agreement between the methods was calculated. Specificity and sensitivity were calculated based on a final interpretation of the results (defined as a reference method) obtained with the current Access Toxo IgG, the AxSYM Toxo IgG and the bioMérieux VIDAS Toxo IgG assays.
Results:

- Blood donors: The agreement between the new Access Toxo IgG and the AxSYM Toxo IgG assays was 97.57% (683/700). According to the reference methods, the new Access Toxo IgG assay displayed specificity and sensitivity of 99.53% and 99.37%, respectively.
- Non selected hospitalised patients: The agreement between the new Toxo IgG and the AxSYM Toxo IgG assays was 97.64% (1781/1824). According to the reference methods, the new Access Toxo IgG assay displayed a relative specificity and sensitivity of 98.89% and 99.70%, respectively.
- Pregnant women: The agreement between the new Toxo IgG and the AxSYM Toxo IgG assays was 98.92% (552/558). According to a reference method, the new Access Toxo IgG assay displayed specificity and sensitivity of 100% and 100%, respectively.

Conclusion: The new Access Toxo IgG assay provides good agreement in comparison with the AxSYM Toxo IgG assay. The new Access Toxo IgG assay displays excellent relative specificity and sensitivity results compared to reference Toxo IgG methods. The new Access Toxo IgG assay can be used either with the Access® Immunoassay System or with the high-throughput UniCel® DxI 800 Access Immunoassay System.

P941 Evaluation of the new ARCHITECT CMV IgM, IgG and IgG avidity assays

K. Lagrou, M. Bodeus, M. Van Ranst, P. Goubau (Leuven, Brussels, BE)

Objectives: A panel of new CMV assays for the ARCHITECT instrument has been developed including a CMV avidity assay based on a new technology. The purpose of this study was to compare the performance of the fully automated CMV IgM, IgG and IgG avidity tests on ARCHITECT with other available assays.
Methods: 503 consecutive fresh patient sera (routine sera) received at the University Hospital laboratory for CMV IgM and IgG testing on AxSYM (Abbott), 100 preselected AxSYM IgM positive sera and 96 sera from 33 pregnant women with a recent CMV primo infection (seroconversion sera) were tested for CMV IgM and IgG on the ARHCITECT (Abbott), VIDAS (BioMerieux) and Dade Behring assays. The seroconversion sera

were also tested with the IgG avidity tests developed on ARCHITECT and VIDAS. The specificity of the avidity tests was assessed on 100 preselected AxSYM IgM negative, IgG positive sera.

Results: The relative agreement for the CMV IgM determination on the routine sera between ARCHITECT and VIDAS, Dade Behring and AxSYM was respectively 97%, 94% and 93% for the CMV IgM tests and 99%, 98% and 98% for the CMV IgG tests. CMV IgM reactivity on ARCHITECT but not with the other assays, occurred only in 1 of the 503 routine sera (0.2%). In 3.0% of routine sera CMV IgM was positive only on AxSYM. CMV IgG avidity was high in 50% of routine sera with ARCHITECT CMV IgM reactivity. All preselected AxSYM IgM positive sera with a low VIDAS IgG avidity were reactive on all IgM assays tested. The specificity of the CMV IgG avidity test was 98% for ARCHITECT and 76% for VIDAS. No high CMV IgG avidity test results were found within the first 3 months after seroconversion with both assays. High avidity was attained earlier on ARCHITECT than on VIDAS. In several patients no gradual increase in avidity was observed after seroconversion. This phenomenon was more frequent with the ARCHITECT avidity test compared to the VIDAS assay. The increase in the avidity values after seroconversion needs further validation.

Conclusion: The correlation between the newly developed CMV IgM and IgG tests on ARCHITECT with the VIDAS and Dade Behring assays was excellent (⩾94%) and was highest between ARCHITECT and VIDAS. The CMV IgG avidity test reliably excluded recent infections and showed an excellent specificity (98%).

P942 Earliest possible diagnosis of seroconversion for toxoplasmosis in pregnancy

V. Meroni, F. Genco, P. Lanzarini, M. Stronati, L. Ciardelli, F. Garofoli, L. Bollani (Pavia, IT)

The early and definitive detection of a recently acquired infection is critical for the clinical management of the mother and her foetus. IgG antibodies are often absent in early phases of infections and IgM antibodies may be non specific and disappear at the end of pregnancy. Therapy usually given as early as possible could affect antibody production. To distinguish early infection from non-specific antibody response we evaluated two routine tests for IgG and for IGM two new confirmation immunoblots and mmunological tests in 39 pregnant women with suspected seroconversion.39 pregnant women negative for anti-*Toxoplasma* IgG (LIAISON Toxo IgG II DIASORIN Italy, VIDAS toxo IgG II Biomerieux France)and positive for IgM with at least one of the two tests routinely used(LIAISON TOXO IgM DIASORIN Toxo IgM ISAGA BIOMERIEUX)were followed weekly to detect the production of anti-*Toxoplasma* IgG. Spiramicyn was given at the first positive IgM test. All samples were also tested with LDBIO TOXOII IgG and LDBIO TOXOII IgM the latter being not commercially available (LDBIO DIAGNOSTICS France). In 12 out of 39 women lymphocyte stimulation was performed using *Toxoplasma* antigen (DIASORIN)and CD25 and Stimulation Index were evaluated.10 women resulted IgM ISAGA and type II WB negative in all these cases no seroconversion was recorded even after therapy interruption. IgM ISAGA and LDBIO TOXO II IgM was positive in 29 women. For 13 patients the seroconversion was proved with the appearance of specific anti-*Toxoplasma* IgG during the follow-up. In 4 they were already present in the first sample by LDBIO TOXOII IgG in 9 IgG antibodies were detected on subsequent samples earlier with LDBIO TOXOII IgG and with LIAISON Toxo IgG assay.9 were also positive in lymphocyte stimulation.13 women were LDBIO TOXOII IgM negative and no IgG was detected with all the tests on later samples even after the treatment was discontinued. In 5 cases lymphocyte stimulation confirmed these results.

Conclusions: In 36 patients an early and correct diagnosis was reached with LDBIO TOXO II IgM. LDBIO TOXO II IgG and LIAISON Toxo IgG II were positive earlier and confirmed the seroconversion several weeks before the other IgG test. In all negative cases it was possible to stop safely the therapy and to reassure the women. No infected woman was missed, all positive women were given the appropriate therapy and prenatal diagnosis was offered. We had three false positive results at IgM (one also with lymphocyte stimulation).

P943 Performance of five commercial immunoblots for serological confirmation of syphilis

C. Roure sobas, M. Brun, P. Miailhes, H. Salord, Y. Gille, S. Tigaud (Lyon, FR)

Objectives: The incidence of syphilis has increased yearly since 2000. Syphilis is famous for its polymorphic presentation and diagnosis is usually established by serology. Nontreponemal test and a specific treponemal test are classically used. Immunoblots (IB) (IgG and IgM) have recently been proposed as confirmatory tests, but without clear indications. Except for Inno-Lia (Innogenetics), performance data are rare. The multiparametric approach is based on antibody responses to 3 immunodominant *Treponema pallidum* recombinant polypeptides (TpN47, TpN17, TpN15) and one synthetic peptide (TmpA) blotted onto strips.

Methods: The present study compared 5 commercial IB IgG tests (InnoLia, Innogenetics; Euroline, Euroimmun; EcoLine, Virotech; Recomblot, Mikrogen; and Virastripe, Servibio) and 3 IgM IBs (InnoLia, Euroline, and Recomblot) in routine. All sera were tested by the rapid reagin plasma test (RPR), the *T. pallidum* hemagglutination assay (TPHA), the immunoglobulin IgG-fluorescent *T. pallidum* absorption assay (IgG-FTA-ABS), the immunoglobulin IgM-fluorescent *T. pallidum* assay (IgM-FTA), and an enzyme immunoassay (IgM-EIA). We tested 44 well-defined sera at different stages of syphilis (clinical and serology findings), 20 sera with an indeterminate serological status for syphilis and 7 samples from subjects with potentially interfering diseases. For 5 patients, we also compared serology results at diagnosis and at 3 to 6 months' follow-up, to investigate antibody kinetics.

Results: All IgG IB assays provided comparable results and confirmed the 44 syphilis. No sera from patients with autoimmune disease or lyme borreliosis were positive. TpN47 and TmpA was the most frequent antigen in all stages of syphilis and band intensity varied with TPHA titer. Anti-TmpA antibody levels tended to fall after treatment, and TNp47 indicated serological scarring.

Whenever ELISA-IgM and FTA-IgM were concordant, the IB IgM test confirmed diagnosis, and identified 4 out of 6 discordant cases (ELISA IgM negative, FTA IgM positive). The recomblot IgM and the InnoLia IgM achieved the highest sensitivities.

Conclusion: The main interest of IB tests lies confirming or ruling out a diagnosis of syphilis in case of discordant screening findings. Further studies are needed to assess application to latent and neonatal syphilis.

P944 Use of the recombinant k39 immunochromatographic strip-test for serological diagnosis of visceral leishmaniasis: experience from Apulia, southern Italy

R. Monno, R. Bruno, E. Di Molfetta, P. Bottalico, C. Rizzo, D. De Vito, L. Fumarola (Bari, IT)

Objective: Visceral leishmaniasis (VL) is endemic in our area, Apulia, Southern Italy. The aim of this study was to evaluate a commercially available membrane-based immunoassay (MBI) using a recombinant protein rk39 as antigen in comparison to the immunofluorescent antibody assay (IFA) for the detection of specific anti-*Leishmania* antibodies.

Methods: A total of 264 individuals including 19 patients with VL (3 of whom HIV-positive), 67 with suspected VL and 40 healthy controls were tested. VL diagnosis was made by microscopic demonstration of *Leishmania* amastigotes in Giemsa stained smears from bone marrow aspirates and/or on the presence of specific antibodies. In a HIV-positive patient diagnosis was performed by the PCR on peripheral blood. IFA and MBI were performed in all 264 sera according to manufacturer's instructions.

Results: The MBI was positive in all the 19 patients with VL (diagnosed by the presence of antibodies by IFA and/or the presence of amastigotes in bone marrow aspirate) and negative in sera from the

remaining individuals. The sensitivity and specificity of MBI was 100%, respectively. The IFA failed to detect anti-*Leishmania* antibodies in the first serum sample of a HIV-positive patient but antibodies were detected in a second serum sample obtained 7 days later. On this patient the MBI was positive on the first serum sample tested. The MBI works well also on HIV–*Leishmania* co-infected patients in whom low yield of serological studies may be a most characteristic finding. Follow up performed on 7 patients with VL showed that both antibodies to *Leishmania* detected by IFA and MBI remain at detectable levels up to 12–24 months. A dilution trial performed on sera of 2 patients showed that a positive reaction by MBI was detectable at serum dilution up to 20,480, indicating that a strong immuno-response is mounted against the rk39 antigen.

Conclusions: The MBI is a reliable test for diagnosis of leishmaniasis and is not only a good alternative in a setting where a reliable enzyme immunoassay or IFA tests are not available, but also in well equipped laboratories because positive results can be obtained in 10 minutes. The cost of MBI in our experience was approximately 8.43 euro per test, compared with approximately 12 euro for IFA. MBI appears highly sensitive, specific, rapid and cost-effective for the serological diagnosis of VL in our location where VL has a low endemicity.

P945 Virus-specific antibody activity of different subclasses of immunoglobulins G in Cytomegalovirus infections

E. Matveeva, A. Burkov, A. Obriadina (Nizhny Novgorod, RU)

Objectives: Patients with primary, reactivated or convalescent phase of Cytomegalovirus (CMV) infections were examined for antiviral antibodies of the IgG subclasses. The purpose of this study was to investigate the diagnostic value of anti- CMV IgG subclasses for diagnosis of acute CMV infection.

Methods: A total of 52 serum samples from patients with different phases of CMV infection were tested for anti-CMV IgG, IgM and IgG avidity by commercially available enzyme immunoassay (RPC “Diagnostic systems”, Russia). Anti CMV IgG specific to envelope glycoprotein (gB) were studied to confirm recent infections. The reactivity pattern of IgG subclasses to individual CMV proteins (pp150, pp52, pp38, pp28) were analysed with subclass specific monoclonal antibodies from Zymed Laboratories Inc., USA.

Results: The distribution of CMV-reactive IgG subclasses among groups with different CMV infection phases was analysed. CMV-specific IgG1 was predominant in all groups. In primary infection frequency of anti-CMV IgG3 is significant higher (75%) than in latent phase (13%, P = 0.001) and reactivated CMV infection (23%, P = 0.032). Frequency of anti-CMV IgG4 is significant higher (62%) for reactivated CMV infection than for convalescent phase (10%, P = 0.001). No difference was observed in total IgG subclass value in all analysed groups.

No significant difference was found for IgG2 and IgG4 reactivity to individual CMV proteins between studied groups. In primary infection anti-pp28 IgG1 was detected rarer (25%) than in reactivated CMV infection (85%, P = 0.018). Among patients with acute CMV infection (recent or reactivated) frequency of anti-pp150 IgG3 positive sera is significant higher (38%) than in group of latent infection (0%, P = 0.001, P = 0.003).

Conclusions: Frequencies of anti-CMV IgG4 and anti-pp150 IgG3 are different for acute and latent CMV infection and anti-CMV IgG3 and anti-pp28 IgG1 – for primary and reactivated CMV infection. The measurement of IgG subclasses reactive with individual CMV proteins may be a sensitive indicator of CMV infection phases.

P946 Significance of laboratory findings for the diagnosis of neurosyphilis

N. Chepurchenko, M. Gladisheva, A. Burkov, A. Obriadina (Nizhny Novgorod, RU)

Objectives: The usage of recombinant *T. pallidum* antigens in ELISA and passive hemagglutination assay (TPHA) has the potential for improvement lab diagnostics of neurosyphilis. The aim of this study was to evaluate the diagnostic relevance of cerebrospinal fluid (CSF)-tests, to analyse antibody reactivity pattern in CSF from neurosyphilis patients by ELISA and TPHA and new criterion of the intrathecal production of specific IgG definition.

Methods: Four full-length recombinant proteins (TmpA, 47, 17, 15 kDa) were expressed in *E. coli* and then used individually to develop ELISA and TPHA tests. The FTA-ABS, TPI, ELISA, TPHA, VDRL, CFT (complement fixation test) tests were performed on CSF samples from 22 patients with a diagnosis of active neurosyphilis, from 4 patients treated for neurosyphilis and from 17 patients without syphilitic CNS involvement. TPHA-IgG titres have been determined in paired serum and CSF samples from 13 neurosyphilis patients and 1 patient without syphilitic CNS involvement.

Results: When CSF was used as diagnostic fluid sensitivities of FTA-ABS, ELISA, TPHA (82.3%, 86.4%, 86.4% accordingly) were higher in comparison with TPI, VDRL, CFT tests (62.5%, 58.8%, 60% accordingly). However, VDRL and CFT demonstrate 100% specificity in contrast with treponemal tests (specificity 75–84.6%). The best result matched with clinical diagnosis of neurosyphilis was demonstrated by next three combinations: FTA-ABS+ELISA+TPHA, FTA-ABS+ELISA+VDRL or FTA-ABS+TPHA+VDRL – 88.4%.

Antibodies specific to 17 kDa (88.9–90.9%) and TmpA (72.2–86.4%) were prevalent in CFS samples. There is no correlation in titers of antibodies specific to individual *T. pallidum* recombinant antigens in paired serum and CFS samples from patients with neurosyphilis. In the same time strong correlation was observed when paired CFS/serum samples from patient without syphilitic CNS were tested.

Conclusions: Different antibody reactivity pattern in paired CFS/serum samples may indicate intrathecal production of antitreponemal antibodies.

P947 Sensitivity and mutant recognition of the DiaSorin liaison HBsAg assay

S. Nick, H. Scheiblauer, E. Spranzi, S. Wacker (Langen, DE; Saluggia, IT; Dietzenbach, DE)

Objectives: Determination of HBsAg is still indispensable for the diagnosis of HBV infection despite additional anti-HBc screening and NAT. Yet, high sensitivity and mutant recognition are the prerequisites for HBsAg detection. The European regulations require an overall sensitivity equivalent to an established device, early detection to be state of the art and recognition of virus variants. The Liaison HBsAg assay was challenged for analytical sensitivity, seroconversion sensitivity and frequently occurring HBV mutants.

Methods: Diagnostic and analytical sensitivity of the Liaison HBsAg assay were assessed using 37 commercial seroconversion panels, internationally recognised HBsAg standards (PEI HBsAg ad and ay, 2nd WHO HBsAg standard and HBsAg mutant samples (4 recombinant constructs S143L (ayw), C76Y/R169H, S53L/ I126N/ S210N, C76Y/ T143M/ F219S and 4 naturally occurring mutants G129H, M133T, G145R, T143L).

Results: Seroconversion data revealed that the Liaison HBsAg assay showed an overall clinical sensitivity in the range of European CE-marked HBsAg tests. Among the 20 HBsAg tests assessed by PEI it ranked at position 9. Analytical sensitivities of the Liaison HBsAg were 0.023 PEI U/ml relating to the PEI HBsAg ad standard and 0.038 PEI U/ml for the HBsAg ay standard. Based on the 2nd WHO HBsAg standard analytical sensitivity was 0.049 IU/ml. In addition, the Liaison HBsAg test detected all natural mutants as well as all recombinant constructs investigated.

Conclusions: Sensitivity of Liaison HBsAg assay meets the current state of the art in the sense of the European regulations. Analytical sensitivity of the Liaison HBsAg complies with the revised European requirement for 0.130 IU/ml relating to the 2nd WHO HBsAg standard. Seroconversion sensitivity is in a good range with other CE-marked assays. The assay shows no deficiencies in the detection of frequently occurring HBsAg mutants.

P948 **Bacteriological and serological aspects of *Chlamydophila pneumoniae* pharyngotonsillitis in adults**

R. Timpanaro, B. Bisignano, A. Stivala, A. Garozzo, A. Castro, G. Tempera (Catania, IT)

Objective: Acute pharyngotonsillitis is one of the most common infections encountered by family physicians. Most patients with acute pharyngotonsillitis have symptoms that can be attributed to infection with a respiratory virus, such as adenovirus, influenza virus, parainfluenza virus, rhinovirus, and respiratory syncytial virus. However, in approximately 30% to 40% of cases, acute pharyngotonsillitis is of bacterial aetiology. Group A beta-hemolytic streptococci (GABHS) are responsible for most bacterial cases of acute pharyngotonsillitis, although other pathogens, such as *Neisseria gonorrhoeae*, *Arcanobacterium haemolyticum*, *Mycoplasma pneumoniae*, and *Chlamydophila pneumoniae*, may be the causative agents in sporadic cases.
To assess whether *C. pneumoniae* plays a role in pharyngotonsillitis, the prevalence of *C. pneumoniae* detection in adult patients with upper respiratory illnesses was investigated.
Methods: Clinical samples from 98 adult patients were sent to our laboratory from family physicians between January 2006 and March 2007. All clinical and serum samples were collected from patients who were diagnosed with pharyngotonsillitis based on clinical symptoms. During the same period, we enrolled 75 healthy subjects without any history of respiratory tract infections in the 3 months before enrolment. The nasopharyngeal swabs were evaluated for isolation of *C. pneumoniae* in cell culture, all specimens were passaged three-times. The presence of chlamydial inclusions was examined by Immunofluorescent (IFA) staining and Giemsa staining.
A commercial microimmunofluorescence (MIF) test was used to measure *C. pneumoniae*-specific IgG, IgM, and IgA antibodies (Labsystems, Helsinki, Finland distributed by Dasit, Italy).
Results: *C. pneumoniae* was detected by isolation in ten patients (10.2 per cent) but in none of the control. Immunofluorescent (IFA) staining and Giemsa staining of 98 pairs of matched swabs detected *C. pneumoniae* in three by both methods, in four by Giemsa staining alone, and in three by IFA alone.
Twenty-four (24.5 per cent) of 98 patients had a positive result for *C. pneumoniae* IgG antibodies and nine (9.2 per cent) for *C. pneumoniae* IgA antibodies. No patient had a *C. pneumoniae* IgM antibodies.
Conclusion: Our results suggest that the therapeutical choice of acute pharyngotonsillitis in adults should take into account the possibility of *C. pneumoniae* infections.

P949 **Laboratory evaluation of UniCel DxI 800 analyser (Beckman Coulter) for HBV and HCV serological markers**

M. Miedouge, F. Abravanel, C. Lalanne, J. Izopet (Toulouse, FR)

Objectives: The UniCel DxI 800 analyser (Beckman Coulter) is a multiparametric immunoassay system with random access that uses magnetic particules separation and indirect chemiluminescent technology.
In this study, intra-assay and inter-assay precision, and a comparison with the Vitros ECi (Ortho Clinical diagnosis) were evaluated for the following virological markers: antibody to hepatitis C virus (anti-HCV) and four hepatitis B virus (HBV) markers i.e. HBsAg, anti-HBc, anti-HBc IgM and anti-HBs.
Methods: Intra-assay precision was determinated by measuring within one run 20 replicates of the manufacturer positive controls. For inter-assay precision, the same controls were tested daily during the evaluation period in 26 to 36 runs depending on the markers.
Comparison of the two analysers was assessed by testing patients sera previously analysed in our laboratory with the Vitros ECi and stored at $-23\pm5^{\circ}$C. Negative and positive samples were compared: respectively 104 and 108 for HBsAg, 120 and 133 for anti-HBs, 225 and 36 for anti-HBc, 103 and 21 for anti-HBc IgM and 109 and 26 for anti-HCV
For the quantitative anti-HBs assay, correlation with the Vitros was determined with the Spearman regression test. Moreover linearity, accuracy and detection limit were evaluated using serial dilutions (from 500 mUI/ml to 10 mUI/ml) of the WHO internationnal standard for anti-HBs (W1042).
Results: Coefficient of variation for intra-assay and inter-assay tests were respectively 0.8% and 4.4% for HBsAg, 2.1% and 5.1% for anti-HBs, 2.4% and 6.2% for anti-HBc, 5% and 8.7% for anti-HBc IgM and 3.7% and 7.4% for anti-HCV.
The concordance rates between the two methods were high: 100% for the five markers except for negative HBsAg sera where one discordant result was observed (99% concordance). Anti-Hbs results appeared statistically correlated either with Vitros results or with the WHO standard ($p<0.01$ with Spearman test). All the five replicates of the 10 mUI/ml sample were detected. The throughput of the analyser was estimated at about 200 tests per hour.
Conclusion: The results of this evaluation confirmed that the five assays meet the criteria of the Common Technical Specifications of the European Union's Directive on In Vitro Diagnostic Medical Devices in terms of specificty and sensitivity. Together with a high throughput, the DXI provides a useful tool for serological diagnosis of HCV anc HBV infection in routine practice.

Host microbial interactions

P950 **Tifacogin and a synthetic TFPI peptide fragment suppress cytokine production due to *Streptococcus pneumoniae* and *Staphylococcus aureus* in whole blood cultures**

Y. Dai, S. Schirm, X. Liu, S. Hardy (Emeryville, US)

Objective: Tifacogin, rTFPI, has demonstrated efficacy in acute inflammation after *Escherichia coli* infection in several animal models of severe sepsis. Tifacogin is currently being evaluated in a phase 3 clinical trial in severe community acquired pneumonia patients. Our goal was to investigate tifacogin activity in bacterially-induced inflammatory disease in an ex vivo model using disease relevant bacteria. The objective of this study was to investigate if cytokine production was reduced by tifacogin and TFPI-derived peptides in an ex vivo model of blood cultures inoculated with *S. pneumoniae* or *S. aureus*.
Methods: Tifacogin and synthetic C-terminal peptides derived from TFPI were prepared and their effect on inflammatory cytokine production in 10% human blood cultures containing Gram+ pathogens including *S. pneumoniae* and *S. aureus* were measured with and without vancomycin. For cytokine analysis, whole blood assay reactions were incubated for 18–20 hours and cell-free supernatants were harvested. Aliquots were used in a custom pro-inflammatory human cytokine panel. Bacterial titers were measured by serial dilution of cultures, plating on appropriate agar and incubation overnight at 37°C.
Results: Addition of tifacogin to vancomycin reduced inflammatory cytokines IL-1B (7 pg/mL compared to 36 pg/mL for vancomycin alone), IL-6 (1100 pg/ml compared to 3450 pg/mL), TNF-a (37 pg/ml compared to 250 pg/mL), and IL-8 (3000 pg/mL compared to 25000 pg/mL) respectively compared to vancomycin alone. Similar changes were noted with other anticoagulants suggesting the effect was tied to clotting inhibition. In combination with vancomycin, a TFPI peptide but not its scrambled control also significantly reduced IL-6, IL-8 and TNF-a levels compared to vancomycin alone. The effects of tifacogin and TFPI peptide reinforced each other to lower cytokines to near baseline levels, suggesting different underlying mechanisms. Similar findings were noted when erythromycin was substituted for vancomycin.
Conclusions: Our results show that tifacogin and an rTFPI peptide demonstrate anti-inflammatory effects by reducing cytokine levels in blood inoculated with *S. pneumoniae* or *S. aureus*. These data suggest that tifacogin has antiinflammatory activity in addition to previously demonstrated anticoagulant activity. Tifacogin and rTFPI peptide fragment may have adjunctive antiinflammatory activity in combination with antibiotics.

P951 IL-17 is associated with severity of invasive meningococcal disease

O. Beran, O. Dzupova, D. Lawrence, M. Holub (Prague, CZ; Albany, US)

Objectives: The aim of the present study was to determine the cytokine profile of plasma and cerebrospinal fluid (CSF) during invasive meningococcal disease (IMD) with use of a multiplex system. The relationship between cytokine concentrations and IMD severity was also assessed.

Methods: A total of 12 patients with IMD were evaluated. Paired plasma and CSF samples were obtained at the time of diagnostic (day 1) and follow-up (day 3–5) lumbar puncture (LP). Plasma and CSF concentrations of 11 biomarkers (TNF-α, IL-1β, IL-6, IL-8, IL-10, IL-12, IL-17, MCP-1, MIP-1β, IL-1Ra, leptin) were analysed using a Luminex® analysis. Disease severity was evaluated using Acute Physiology and Chronic Health Evaluation (APACHE) II score, Sequential Organ Failure Assesment (SOFA) score and Glasgow Coma Scale (GCS) score.

Results: Plasma concentrations of IL-6, IL-10, IL-17 and IL-1Ra were associated with APACHE II on day 1. With regard to the severity of organ dysfunction on day 1, plasma IL-6, IL-8 and IL-10 concentrations showed the best correlation with SOFA. Unlike plasma cytokines, CSF concentrations were not associated with the disease severity.

Conclusion: Multiple cytokine analysis revealed cytokine patterns associated with inflammatory response during IMD. Moreover, the study is first to demonstrate that the increased IL-17 plasma concentration is associated with IMD severity. Since IL-17 is mainly produced by a CD4+ T cell subset (Th17 cells), our results suggest an important role of these cells in the IMD pathophysiology. Acknowledgement. The study is supported by a grant IGA NR/9316–3.

P952 Waddlia chondrophila multiplies within human macrophages in a vacuole associated to the endoplasmic reticulum

G. Goy, A. Croxatto, G. Greub (Lausanne, CH)

Objectives: Waddlia chondrophila is an obligate intracellular bacteria which belongs to the Chlamydiales order. It was isolated twice from aborted bovine foetuses, first in 1990 in the United States and then in 2002 in Germany. A serological study supported the abortigenic role of Waddlia in bovine species and inoculation of a pregnant cow with this intracellular bacteria was associated with foetal death within 2 weeks. Recently, we observed a strong association between the presence of anti-Waddlia antibodies and human miscarriage. To further investigate the pathogenic potential of W. chondrophila in humans, we studied the entry and the multiplication of this obligate intracellular bacteria in human macrophages.

Methods: Monocyte-derived macrophages were incubated with living or heat-inactivated bacteria for 15 min at 37°C after a centrifugation step. Cells were then washed and further incubated for different periods at 37°C. Entry was assessed by confocal microscopy and bacterial growth was quantified using immunofluorescence with mice anti-Waddlia antibodies and real-time PCR. Intracellular traffic of W. chondrophila in human macrophages was assessed by studying the co-localisation of the bacteria with various cell markers.

Results: Confocal microscopy confirmed that W. chondrophila is able to enter into human monocyte-derived macrophages. W. chondrophila organisms were shown to multiply readily within macrophages. The proportion of infected macrophages increased from 13% at day 0 to 96% at day 4, and the mean number of bacteria per macrophage (assessed by immunofluorescence) increased of more than 2 log in 4 days. This growth was confirmed by real-time PCR with a 3 log increase in 4 days and was associated with a decrease in the number of macrophages. As expected, the heat-inactivated bacteria, which also entered into the macrophages, did not increase over time and exhibited no cytopathic effect. Using immunofluorescence and confocal microscopy, we showed that W. chondrophila escape the endocytic pathway and co-localise with markers of the endoplasmic reticulum.

Conclusion: This study shows that W. chondrophila enters and multiplies logarithmically within human macrophages suggesting its possible human pathogenicity.

P953 *Streptococcus pneumoniae*, *Neisseria meningitidis* and *Haemophilus influenzae* elicit distinct patterns of inflammatory parameters in cerebrospinal fluid of patients with bacterial meningitis

D. Grandgirard, R. Gäumann, G. Pluschke, S. Leib (Berne, Basel, CH)

Objectives: Morbidity and mortality of meningitis caused by *S. pneumoniae*, *N. meningitidis*, and *H. influenzae*, the three major causes of bacterial meningitis, differ dramatically with *S. pneumoniae* causing the highest incidence of neurological disabilities and death. Pathogenetic mechanisms underlying these differences may involve inflammatory reactions of the brain in response to the different invading pathogens. Inflammatory mediators in cerebrospinal fluid (CSF) from patients suffering from bacterial meningitis caused by the three different bacterial species were assessed with the aim to identify inflammatory mechanisms that contribute to the pathogen related differences in outcome.

Methods: A defined panel of inflammatory parameters were assessed in CSF from patients with confirmed meningitis due to *S. pneumoniae* (n = 32), *N. meningitidis* (n = 38), or *H. influenzae* (n = 3). Concentrations of cytokines, chemokines and matrix-metalloproteinase-9 (MMP-9) were assessed by a microsphere-based multiplex assay. In addition, the concentration of MMP-9 was determined by gelatine gel zymography. The activity of nitric oxide synthase was determined by measuring nitrate/nitrite levels.

Results: IL-2 (Kruskall-Wallis $p<0.03$), IFN-gamma ($p<0.03$), and MCP-1 ($p<0.01$) were found to be differentially up-regulated during bacterial meningitis caused by the three pathogens, with *S. pneumoniae* triggering the highest, and *H. influenzae* the lowest CSF concentrations of these cytokines. CSF levels of MMP-9 also differed among the pathogens (one way analysis of variance $p<0.001$) with levels in pneumococcal meningitis being significantly higher than in meningitis caused by *H. influenzae* (Bonferroni's $p<0.05$). Nitric oxide synthase activity in CSF did not differ for the three causative pathogen.

Conclusion: From the inflammatory parameters assessed, concentrations of IL-2, IFN-gamma, MCP-1, and MMP-9 were significantly higher in CSF samples from patients with meningitis caused by *S. pneumoniae* compared to *H. influenzae* and *N. meningitidis*. The higher case fatality rates and incidence of neurological sequelae caused by pneumococcal meningitis compared to meningococcal or *H. influenzae* meningitis may be associated with an increase in these inflammatory parameters.

P954 The host response in pneumococcal meningitis: differential transcriptome analysis in cerebral cortex and hippocampus

M. Wittwer, J. Rohrbach, S.L. Leib (Berne, CH)

Background: For bacterial meningitis (BM) treatment options are insufficient as evidenced by a high mortality of up to 30% and the occurrence of neurological sequelae in up to 50% of the surviving patients. Knowledge on the diseases processes is prerequisite for improvements in therapy. By setting the global gene expression profile in the context of biological meta-data resources we aimed to unravel the pathological processes which determine the outcome of bacterial meningitis.

Methods: An infant rat model of experimental pneumococcal meningitis (PM) was used. Brain regions prone to injury e.g. the cortex and the hippocampus were dissected form animals in acute and late phase of the disease e.g. at 24 and 72 h after infection. Gene expression profiles were assessed with Affymetrix GeneChip® Rat 230 2.0 arrays. Significance of transcriptomic changes were calculated with a moderated Bayesian t-statistics using the limma package. GO statistics was performed by the GOstats software packages provided by the Bioconductor project.

Results: From 31,000 transcripts of the rat genome represented on the chip, approximately 17,000 were detected in both control and infected

animals. 3600 genes were found to be significantly (FDR Benjamini-Hochberg $p \leqslant 0.05$) regulated at 24 h.p.i and approx. 1100 genes at 72 h.p.i.
Gene Ontology statistics revealed that genes which were regulated at both time points after infection were mainly involved in immunological and inflammatory processes. This observation applies for both the cortex and the hippocampus. In the cortex the dominant process was angiogenesis at 24 h, while it was neurotransmitter signalling at 72 h after infection. Genes found to be regulated in the hippocampus at 24 h.p.i were mainly involved in apoptosis shifting to neurogenesis at 72 h.p.i.
Conclusion: By integrating differential gene expression data in the context of biological research databases this study expands the current knowledge of pathways of injury and regeneration in BM. This approach identified angiogenesis, neurotransmitter signalling, apoptosis and neurogenesis as targets for the development of new therapeutic strategies.

P955 Apoptosis of T lymphocytes in the culture of peripheral blood mononuclear cells from patients with late Lyme arthritis

S. Grygorczuk, J. Osada, J. Zajkowska, M. Kondrusik, T. Chmielewski, R. Swierzbinska, S. Pancewicz, M. Dabrowska, S. Tylewska-Wierzbanowska (Bialystok, Warsaw, PL)

Objectives: Apoptosis of activated T lymphocytes is essential in physiologic regulation of inflammatory and immune response. Lymphocyte susceptibility to apoptosis may be increased in immune deficits and decreased in autoimmune disorders. The pathogenesis of chronic articular symptoms in Lyme borreliosis (Lyme arthritis – LA) is unclear and has been hypothesised to involve aberrant immune response, including possible autoimmunity. We studied apoptosis of peripheral T lymphocytes obtained from patients with late LA and cultured in presence of *Borrelia burgdorferi* sensu lato (*B. burgdorferi*) antigens. We checked for abnormalities in apoptosis rate, especially for decreased susceptibility to apoptosis which might be a hallmark of uncontrolled inflammatory/immune response or autoimmunity.
Methods: Peripheral blood mononuclear cells (PBMC) from 23 subjects: 14 patients with LA persistent or recurrent for > 6 months (LA group) and 9 persons with no clinical suspicion or after exclusion of Lyme borreliosis (control group – C) were incubated for 48 hours with no stimulation or with addition of non-viable *B. burgdorferi* spirochetes: *Borrelia afzelii* VS 46110 (B.a.), *B. garinii* 20047 (B.g.) or *B. burgdorferi* sensu stricte B-31 (B.ss.) as antigenic stimulation. Fraction of T lymphocytes (CD3+ cells) undergoing apoptosis was measured by flow cytometry with annexin-V binding assay.

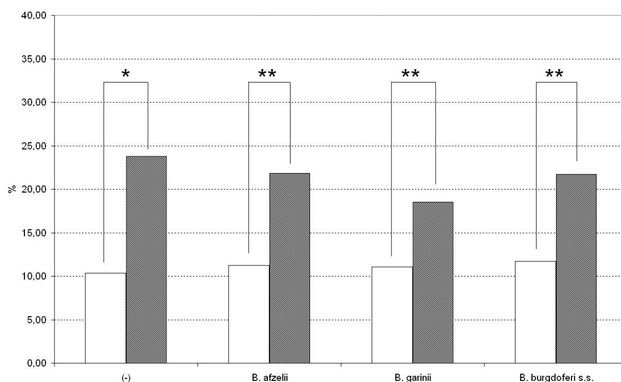

Figure. Fraction of apoptotic T cells (median) in the 48-hour culture either unstimulated (–) or stimulated with antigens of three *B. burgdorferi* genospecies. Empty bars – healthy controls, filled bars – Lyme arthritis patients: $^*p < 0.05$, $^{**}p < 0.01$.

Results: There was a significantly higher fraction of annexine-V positive (apoptotic) T cells in LA (median values – 18–25%) than in C group (10–12%), both with and without antigenic stimulation (Fig). The T cell apoptosis tended to be increased in presence of *B. burgdorferi*, but the effect was weak and statistically significant only in the study population analysed as a whole (LA + C), with rate of apoptosis rising under antigenic stimulation by a median of 10–17% of the baseline (i.e of the value found in unstimulated culture).
Conclusions: No proof of decreased apoptosis of T lymphocytes in late LA was found. Peripheral CD3+ cells from LA patients appear to be more prone to apoptosis in culture, independently of the exposition to *B. burgdorferi*. The role of this phenomenon in the pathogenesis of LA is not clear and may require further study. Some pro-apoptotic effect of *B. burgdorferi* s.l. on human CD3+ cells was observed, which may reflect spirochete's natural defence mechanism against host's immune system.

P956 Nramp1 limits the intracellular growth of *Salmonella typhimurium* by impairing bacterial iron uptake and strengthening macrophage effector functions

M. Nairz, G. Fritsche, I. Theurl, M. Theurl, S. Mair, R. Bellmann-Weiler, H.C. Barton, G. Weiss (Innsbruck, AT; Southampton, UK)

Objectives: Natural-resistance associated macrophage protein 1 (Nramp1) is a phagolysosomal transmembrane protein which acts as a transporter for protons and divalent ions including iron. Nramp1 functionality is associated with an increased resistance against various intracellular pathogens including leishmania, mycobacteria and salmonellae.
Methods: We investigated the regulation of iron homeostasis and immune function in RAW264.7 macrophages stably transfected with functional or non-functional Nramp1 in response to infection with *Salmonella typhimurium*, the causative agent of murine typhoid fever.
Results: Macrophages bearing functional Nramp1 displayed a reduced expression of transferrin receptor 1, resulting in the decreased acquisition of transferrin-bound iron. In contrast, the expression of the transmembrane iron-exporter, ferroportin 1, and in parallel cellular iron release was significantly higher in *Salmonella*-infected Nramp1-functional macrophages as compared to phagocytes lacking Nramp1. Conceivably, Nramp1 functionality caused a reduction in the cytoplasmatic iron pool within macrophages. Additionally, Nramp1-expressing macrophages were capable of limiting the intracellular persistence of *S. typhimurium* significantly better as compared to cells non-functional for this protein. This antimicrobial effect of Nramp1 was characterised by the reduced iron access by engulfed *Salmonella* and the increased formation of nitric oxide, tumour necrosis factor and interleukin-6 by infected phagocytes.
Conclusions: Our data suggest that the protective effects of Nramp1 may be partly attributable to its capacity to reduce the iron availability within phagocytes, an effect which limits microbial iron access while concomitantly strengthening macrophage immune effector functions.

P957 Interferon-gamma limits the availability of iron for intramacrophage *Salmonella typhimurium*

M. Nairz, G. Fritsche, S. Mair, M. Theurl, I. Theurl, A. Schroll, P. Brunner, K. Hantke, G. Weiss (Innsbruck, AT; Tubingen, DE)

Objectives: In stimulating effector functions of mononuclear phagocytes, interferon-gamma (IFN-γ) is of pivotal importance in host defence against intramacrophage pathogens including salmonellae. As the activity of IFN-g is modulated by iron and since a sufficient availability of iron is essential for the growth and proliferation of pathogens, we investigated the regulatory effects of IFN-γ on iron homeostasis and immune function in murine macrophages infected with *Salmonella enterica* serovar Typhimurium (*S. typhimurium*).
Methods: We investigated the effects of IFN-γ on iron homeostasis and immune function in RAW264.7 macrophages in response to infection with *Salmonella typhimurium*.
Results: In *S. typhimurium*-infected phagocytes, IFN-γ caused a significant reduction of iron uptake via transferrin receptor 1. In parallel,

we observed an enhanced efflux of iron from *Salmonella*-infected macrophages upon activation with IFN-γ, which could be traced back to an enhanced expression of the iron exporter ferroportin 1. Moreover, the expression of haem oxygenase 1 and of the siderophore-capturing antimicrobial peptide lipocalin 2 was markedly elevated following bacterial invasion, with IFN-γ exerting a super-inducing effect. This observed regulatory impact of IFN-γ reduced the intracellular iron pools within infected phagocytes, thus restricting the acquisition of iron by engulfed *S. typhimurium* while concomitantly promoting NO and TNF-α production.
Conclusion: Our data suggest that the modulation of crucial pathways of macrophage iron metabolism in response to IFN-γ concordantly aims at withdrawing iron from intracellular *Salmonella* and at strengthening macrophage immune response functions. We therefore propose that these regulations reported herein reflect novel antibacterial effects of IFN-γ being consistent with the principles of nutritional immunity.

P958 Inflammatory cell infiltration and inflammatory cytokines: indicators of *Streptococcus agalactiae* infection in experimental mouse mastitis

G. Trigo, A. França, M. Dinis, R. Gil da Costa, E. Bonifácio Andrade, P. Ferreira, D. Tavares (Porto, PT)

Streptococcus agalactiae is a major contagious pathogen causing mastitis highly adapted to survive in bovine mammary gland.
Objectives: This study focuses on the use of a mouse model of *Streptococcus agalactiae*-induced mastitis as a practical approach for regarding the pathogenesis of the bacteria.
Methods: BALB/c mice in 10–15 th day of lactation were intramammary (i.ma) challenge on both L4 (on the left) and R4 (on the right) abdominal mammary glands with 10^8 cells of *S. agalactiae* isolated from bovine mastitis (infected animals) or with PBS (control animals). Throughout the study the colonisation was evaluated by bacterial counts (CFU) in the mammary gland, kidneys, spleen and liver. Mammary tissue alterations were evaluated by haematoxylin-eosin staining of mammary sections. Cytokine production in the mammary gland during infection was evaluated by ELISA.
Results: *S. agalactiae* i.ma infection showed that the bacteria replicates in the mammary gland and peaked 24 h later. At the same time, a massive infiltration of polymorphonuclear cells (PMNs) and an increase in IL-1β, IL-6 and TNF-α (inflammatory cytokines) levels were detected in the mammary gland. After this, a gradual decrease on bacteria load was observed which was accompanied by a decrease in the number of PMNs and an increase of macrophages and lymphocytes, indicating an evolution into a chronic process in the mammary tissue. A decrease in the levels of TNF-α, IL-1beta and IL-6 were observed in the mammary gland 72 h after infection, which was accompanied by an increase in the levels of IL-12 and IL-10. Dissemination of the bacteria from the mammary glands to the kidneys, spleen and liver was observed 6 hours after infection, with a peak of the CFU after 12 hours for the kidneys and spleen and after 24 hours for the liver. The bacterial load in these organs was significantly lower than the one observed in the mammary gland, throughout the study.
Conclusion: The mouse model of infectious mastitis proposed here is suitable and less costly than cows for the study of pathogenesis of *S. agalactiae* and it can be used as a tool for evaluating potencial vaccines against mastitis induced by *S. agalactiae*.
This work was supported by the Fundação da Ciência e Tecnologia (FCT) grant POCTI/CVT/57144/2004 and FEDER

P959 Crucial role of IFN-gamma receptor in murine *Legionella longbeachae* infection

I. Gobin, K. Selenic, Z. Trobonjaca, M. Doric, M. Susa (Rijeka, HR)

Objectives: *Legionella longbeachae* serogroup 1, a facultative intracellular pathogen is a causative agent of life-threatening pneumonia. Human infection is particulary common in Australia, but sporadic infections have been documented in other countries. Previous studies have shown that activation of U937 macrophages with interferon-gamma (IFN-g) restricts the growth of *L. longbeachae*. In this study we decided to explore the role of IFN-g receptor in *L. longbeachae* mice infection. We explored the kinetics of bacterial multiplication and patohistological changes in IFN-gR –/– knock out and C57Bl/6 mice.
Methods: Pathogen-free 6- to 10-weeks-old IFN-gR –/– and C57Bl/6 (control) mice were infected by intratracheal inoculation with *L. longbeachae* serogroup 1 (clinical isolate D4968) using a dose of 10^3 CFU. We determined the mortality rate and bacterial clearence from the lungs of infected mice at different time points post infection. We also followed the patohistological changes in these organs during 72 hours of infection.
Results: Our results showed a dramatic difference in the mortality rate between IFN-gR –/– and control C57Bl/6 mice. After intratracheal infection with 10^3 CFU of *L. longbeachae* all IFN-gR –/– mice died within 5 days, while control mice survived the infection. Mice infected with 10^3 CFU of *L. longbeachae* were not able to overcome infection for more than 5 days. In contrast, control mice could reduce the bacterial burden in the lungs below the assay detection level 14 days p.i. They, however, showed focal peribronchiolar inflammatory cell infiltration with basement membrane injury, three to seven days after infection. On the other hand, IFN-gR –/– mice developed severe bronchopneumonia with destruction of the alveolar wall and infiltration of the interstitial tissue within neutrophils and lymphocytes three days after infection.
Conclusion: Our results shows that IFN-g receptor plays a crucial role in the host defence against *L. longbeachae* serogroup 1 infection. The findings suggest that retardation of the host immune response caused by deficiency of IFN-gR, might allow bacteria to grow and cause fulminant pneumonia.

P960 The degree of invasiveness of *Campylobacter jejuni* influences cytokines induction in the human monocytic cell line THP-1

A. Al-Muraikhy, K. Tabbara, G. Botta (Dhahran, SA; Manama, BH)

Background: *Campylobacter jejuni* can cause enteritis that is associated with an acute inflammatory response. *C. jejuni* can penetrate the intestinal epithelial barrier and interact with leucocytes, inducing proinflammatory cytokines. The severity of clinical symptoms is related to strain differences. We studied the in vitro invasiveness of eight human isolates of *C. jejuni*, which possess three, two, or none of the virulence genes cdtB, ciaB and iam, with the human monocytic cell line THP-1 and determined the levels of cytokines (IL-1, IL-6, IL-8, IL10, IL 12 and TNF) induced.
Methods: The invasion assay was carried out in 24 wells plate with a multiplicity of infection of 200:1 for 90 minutes followed by treatment with Gentamicin for 120 minutes. Cells were lysed with 0.01% triton and plated to determine the intracellular organisms /cell. Semi quantitative RT-Multiplex PCR was used to assess the kinetics of cytokine mRNA expression in similarly infected cells and ELISA for cytokine levels.
Results: Invasiveness directly correlated with possession of virulence genes, with the most invasive isolates possessing all three genes, followed by those possessing cdtB and ciaB, followed by those with cdtB and iam, while the least invasive were those lacking all three genes. As for cytokine mRNA expression, TNF was most significantly correlated with invasiveness, with IL-1 and IL-8 closely following, while expression of IL-6, IL-10 and IL-12 was essentially similar for all isolates. Cytokine protein expression on the other hand showed a significant difference between one of the most invasive and least invasive of the isolates with respect to TNF and IL-8 and lower differences with respect to IL-1.
Conclusion: *C. jejuni* infection of monocytoid cells triggers expression of proinflammatory cytokines, most significant of which is TNF. This appears to correlate with the virulence of the isolate and might be responsible for the severity of pathology and symptoms.

P961 **The Toll-like receptor 2 agonist Pam3CSK4 induces microglia-mediated neuronal cell death in vitro**

S. Ebert, M. Zeretzke, T. Hoffmann, L. Rollwagen, S. Bunkowski, H. Schmidt, M. Goos, R. Nau (Göttingen, DE)

Objectives: Microglial cells, the major constituents of innate immunity within the brain, express Toll-like receptors (TLR) recognising exogenous and endogenous ligands. Upon treatment with agonists of TLR 2, TLR 4, and TLR 9, primary mouse microglial cells change their morphology and release nitric oxide and inflammatory cytokines. Activated microglia can injure neurons. We investigated the influence of TLR 2-activation on neuronal viability in vitro.
Methods: Primary mouse cortical neurons and co-cultures of primary mouse cortical neurons and primary mouse microglial cells (ratio 2:1) were treated with the TLR 2-agonist Pam3CSK4 (Tripalmytoyl-cysteinyl-seryl-(lysyl)3-lysine; 10 μg/ml) in combination with interferon-gamma (100 U/ml) for 72 hours. Control cultures were exposed to interferon-gamma alone for 72 hours. Cells were fixated in 4% formaldehyde and stained with the neuronal marker Map-2, the microglial marker isolectin B4, and haemalum. Viability of neuronal cells was assessed by a blinded observer and by measurement of the Map-2-stained area using the image processing and analysis program WCIF ImageJ. Student's t-test was perfomed to analyse differences between groups.
Results: Treatment with Pam3CSK4 did not affect the viability of neurons in the absence of microglial cells (Map-2 stained area: 102% in Pam3CSK4-treated cultures versus 100% in control cultures, $p = 0.904$). In co-cultures of neurons and microglial cells, however, treatment with Pam3CSK4 led to visible neuronal damage reflected by a significant reduction of the Map-2 stained area of approximately 20% ($p<0.05$).
Conclusion: The TLR 2-agonist Pam3CSK4 induces microglia-mediated neuronal damage in vitro. During bacterial meningitis, TLR 2 is stimulated by bacterial products, e.g. bacterial lipoprotein. The activation of microglial cells by agonists of TLR 2 might contribute to the neuronal damage in patients with bacterial meningitis leading to an impaired clinical outcome.

P962 **Role of invariant NKT lymphocytes in the hepatic granulomatous response to *Leishmania donovani* infection**

A.S. Drogoul, F. Robert-Gangneux, M. Lisbonne, B. Turlin, C. Guiguen, A. Herbelin, M. Samson, J.P. Gangneux (Rennes, Paris, FR)

Objectives: Visceral leishmaniasis (VL) is a life-threatening infection due to protozoan parasites from the *Leishmania* genus. *L. donovani* in India and East Africa, and *L. infantum* in the mediterranean basin as well as in Brazil are the responsible species for VL. During VL, the hepatic granulomatous response is correlated to the parasitic clearance. However, cellular organisation of mature granulomas is still not totally understood, but seems to involve NKT cells. This particular cell population, at the interface of innate and acquired immunity harbours surface molecules from both NK and T (TCRab) cells. Among NKT cells, invariant NKT lymphocytes (iNKT) are hepatic parenchymatous cells that harbours a semi-invariant TCR, Valpha14-Jalpha18, associated to restricted beta chains. Here, we analyse their role in the granulomatous response during liver infection with *L. donovani* in a murine model deleted in iNKT cells.
Methods: C57BL/6 Ja18–/– mice and congenic wild-type mice were infected with *L. donovani* promastigotes. At days 15, 30 and 60, groups of 4 mice were sacrificed in order to analyse:
– the hepatic parasitic load on May Grunwald-Giemsa stained smears,
– the hepatic granulomatous response on hemalun-eosin-safran stained histological sections,
– the hepatic damage that was evaluated by dosing alanine aminotransferase (ALT), aspartate aminotransferase (AST), lactico-dehydrogenase and alcaline phosphatase levels in the serum.
Results: Compared to wild-type mice that rapidly control the infection, iNKT–/– mice presented with significantly higher hepatic parasitic loads until 10-fold more, at D15 and D30. In parallel, the histologic examination of liver sections displayed a delay in the granuloma maturation. iNKT–/– mice presented at D30 with few large granulomas (13.3% with > 25 cells) versus 33.6% in wild-types, and granuloma maturation was reached in 20% of them versus 50%, respectively. At D60, 40% of the granulomas were matures in iNKT–/– mice and the parasitic loads declined until similar results to wild-types. Hepatic enzyme dosages showed a similar hepatocyte damage in both groups without statistically significant difference.
Conclusion: Finally, our data underline the role of iNKT lymphocytes in the early and efficient organisation of hepatic granuloma that warrants a clearance of parasites. In C57/Bl6 mice that exhibit a resistant phenotype to *Leishmania* infection, the settlement of the adaptative response allows a definitive cure of the infection.

P963 **Iron overload favours the elimination of *Leishmania infantum* from mouse tissues by enhancing the production of reactive oxygen species**

S. Costa, S. Pereira, C. Teixeira, A. Tomás, R. Appelberg, S. Gomes (Porto, PT)

Objectives: We have previously determined that iron overload decreases the growth of *Leishmania infantum* in the liver and spleen of a susceptible mouse strain. The purpose of this work was to investigate if the inhibitory effect of iron overload on the growth of this protozoan is dependent on the production of reactive oxygen species by the macrophagic NADPH oxidase.
Methods: To achieve this goal, we used mice genetically deficient in the p47phox subunit of NADPH oxidase (p47phox knock-out). Control and knock-out mice were treated with iron-dextran (10 mg) or saline solution and 10 days later were infected with *L. infantum*. Mice were sacrificed two weeks after infection and the parasite load was determined in the liver and spleen.
Results: In both organs, iron overload decreased *L. infantum* growth in control mice but not in knock-out mice, indicating that the mechanism through which iron exerts its inhibitory effect on the growth of the parasite is dependent on the production of reactive oxygen species by the host cell.
Conclusion: Iron overload inhibits *L. infantum* growth in mice through the production of reactive oxygen species by NADPH oxidase, a potent antimicrobial mechanism to which *Leishmania* is susceptible.

P964 **Heat-shock response in *Brucella abortus***

N. Amir Mozaffari, R. Rajabnia (Tehran, IR)

Objectives: Heat shock proteins are highly conserved molecules and serve a variety of functions in bacterial cells including protein folding and transport. They mainly serve to protect cells from various forms of stresses including heat shocks. In reference to the potent antigenicity of hsp and its activation of macrophages, the differences in virulence of *Brucella* cells may be originated from differences in patterns of response to heat shocks induced by the high degrees of fever that is usually manifested in brucellosis.
Methods: Five *B. abortus* strains, isolated from human and cows, were subjected to 39, 40, and 42 Celsius degrees heat treatments. The bacterial whole cell proteins were extracted and resolved by SDS-PAGE electrophoresis. Western blottings were used to detect antibody production against the extracted bacterial proteins especially hsp60 in both control and patient sera.
Results: SDS-PAGE gels revealed protein bands mainly in the range of 10–100 KDa. The amounts of a 60 KDa protein band (hsp60) was significantly enhanced following heat shocks in relation to the unheated bacterial cells. The heat shock response points to a significant higher production of a 60 KDa protein (hsp60). The sera from brucellosis patients reacted with several of these cell derived protein bands in western blots, none of which were reactive with sera from healthy individuals. The western blot protein bands showed striking differences.
Conclusion: The results of this study point to the immunogenic properties of *Brucella* heat shock proteins, especially the overwhelming

response towards hsp60. Therefore, hsp60 can be an appropriate antigenic candidate for engineering subunit vaccine against *Brucella*, as well as for ELISA test development.

P965 Deletion of a glycosyltransferase in *Enterococcus faecalis* leads to abolishment of glycolipid synthesis and increased susceptibility to opsonophagocytic killing

I. Toma, I. Sava, C. Theilacker, M. Heizmann, M. Halima, J. Huebner (Freiburg, DE)

Objective: Enterococci are generally considered a commensal of the human gastrointestinal tract but may also cause bacteraemia, urinary tract infections, abdominal infections and endocarditis. We have shown previously that lipoteichoic acid (LTA) is the target of opsonic antibodies against *Enterococcus faecalis*. Glycolipids are important in the maintenance of membrane elasticity and constitute the lipid moiety necessary for anchoring LTA in the cell membrane.
Methods: A non-polar deletion mutant was created in gene EF2890 of *E. faecalis* 12030 by targeted mutagenesis. Bacterial glycolipids were analysed by a modified Blight-Dyer extraction and detected by thin-layer chromatography. Cell lysates were characterised by western blot using rabbit antibodies raised against whole bacterial cells and purified LTA. An opsonophagocytic assay (OPA) was used to test the susceptibility of the wild-type strain and delta-EF2890 against rabbit antisera. The hydrophobicity was analysed by comparing distribution in hydrophilic and hydrophobic solvents. LTA was quantified by ELISA using antibodies raised against enterococcal LTA.
Results: Homology search revealed that EF 2890 shares high similarity with alMGS, a glycosyltransferase from Acheloplasma laidlawii, involved in the synthesis of monoglycosyldiacylglycerol (MGlcDAG). MGlcDAG is a major constituent of bacterial cell membranes. Wild type and delta-EF2890 displayed equivalent growth kinetics and stationary phase survival. Glycolipid analysis by TLC revealed that inactivation of EF2890 leads to a complete abolishment of glycolipid synthesis. The loss of glycolipids resulted in a retarded motility of LTA in SDS-PAGE. The content of LTA in the cell wall of the mutant strain was significantly higher than in the WT. Compared to the WT, EF2890 mutant was more susceptible to opsonophagocytic killing mediated by polyclonal rabbit antiserum raised *E. faecalis* 12030.
Conclusions: Deletion of the glycosyltransferase EF2890 resulted in complete abolishment of glycolipid synthesis. The absence of glycolipids leads to an increased retention of LTA on the cell wall and increased suscebtibility to antibody-mediated opsonic killing. Since we have shown previously that opsonophagocytic killing of *E. faecalis* 12030 is exclusively mediated by LTA-specific antibodies, our results suggest that an increased epitope denisity may facilitate the deposition of opsonic antibodies.

P966 *Acinetobacter baumannii* outer membrane protein A targets voltage-dependent anion channel and induces early-onset apoptosis and delayed-onset necrosis in dendritic cells

J.S. Jin, J.S. Lee, J.W. Kim, C.H. Choi, H.Y. Chung, J.C. Lee (Daegu, Busan, KR)

Objectives: *Acinetobacter baumannii* outer membrane protein A (AbOmpA) is an important pathogen-associated molecular patterns that has been associated with host cell death. We investigated the dendriric cell (DC) death in response to AbOmpA and its implication of immune responses against *A. baumannii*.
Methods: Murine bone marrow-derived DCs were treated with recombinant AbOmpA. Subcellular localisation of AbOmpA was determined by confocal microscopy and immunoprecipitation. Molecular mechanisms of DC death were analysed by flow cytometry and Western blot assay. Wild-type *A. baumannii* and isogenic AbOmp (–) mutant strains were intraperitoneally infected in the mice.
Results: AbOmpA induces DC death, which started as apoptosis and later transformed to necrosis. AbOmpA targets mitochondria and interactes with voltage-dependent anion channel (VDAC). Apoptotic cell death is preceded by the transient elevation of mitochondrial transmembrane potential and an increase of intracellular reactive oxygen intermediates (ROIs). These events are followed by a loss of mitochondrial transmembrane potential, mitochondrial swelling, activation of caspases, and externalisation of phosphatidylserine. Both apoptosis and necrosis of AbOmpA-treated DCs are significantly inhibited by N-acetyl cysteine, suggesting that ROIs are responsible for the induction of apoptosis and necrosis. AbOmpA induces maturation of DCs, but ROIs produced by DCs impairs the cytokine production of T cells interacted with DCs and induces T cell killing. Wild-type *A. baumannii* impars maturation of DCs and results in high mortality in mouse model, whereas AbOmpA knock-out mutant induces maturation of DCs and no animals died.
Conclusion: Our study indicate that VDAC-targeting AbOmpA induces DC death and the subsequent dysfunction of T cells for the adaptive immunity. Thus, we propose mmune dysfunction mechanisms of *A. baumannii*-infected hosts regarding the mitochondrial targeting of bacterial proteins.

P967 Tolerability of N-chlorotaurine, a new endogenous antiseptic, in the bronchopulmonary system

A. Pinna, R. Geiger, B. Treml, L. Barnickel, C. Walther, S. Scholl-Bürgi, W. Gottardi, R. Arnitz, C. Sergi, A. Löckinger, M. Nagl (Innsbruck, AT)

Objective: N-chlorotaurine, an important representative of the long-lived oxidants produced by human leukocytes, can be applied in human medicine as an endogenous antiseptic. This study was designed to evaluate the tolerability of inhalative N-chlorotaurine (NCT) in the pig model.
Methods: Anesthetised pigs inhaled test solutions of 1% NCT (n = 7), 5% NCT (n = 6), or 1% NCT plus 1% ammonium chloride (n = 6), and 0.9% saline solution as a control (n = 7), respectively. Applications were performed every hour within four hours, i.e. 4 inhalations in total, with 5 ml each. Lung function, blood oxygenation, and circulation were monitored. Pharmacokinetics were investigated by oxidation capacity in bronchial fluid and by determination of taurine and chloride in serum. One hour after the last dosing the animals were euthanised, and lung samples for histology were removed.
Results: Arterial pressure of oxygen (PaO2) decreased significantly over the observation period of 4 hours in all animals. Compared to saline, only 1% NCT + 1% NH4Cl led to significantly lower PaO2 values at the 4 hours measurement (62 mmHg ± 9.6 vs. 76 mmHg ± 9.2, p = 0.014). The corresponding increase in alveolo-arterial difference of oxygen partial pressure (AaDO2) was significantly higher only in the 1% NCT + 1% NH4Cl than in the control group ($P < 0.01$), too. Pulmonary artery pressure increased about 9.7 mmHg by 5% NCT, about 7.8 mmHg by 1% NCT + 1% NH4Cl ($P < 0.05$ versus control), about 4.3 mmHg by 1% NCT ($P > 0.05$ versus control), and about 6.7 mmHg by saline.
Histological investigations revealed inflammatory reactions, districts with atelectasia, districts with emphysema, and districts with fragmentation of fibers in both the test groups and in the saline group with no statistical difference.
There was no systemic resorption of NCT detectable. Local inactivation of NCT below detectable levels took place within 30 min. The concentration of NCT tolerated by A549 lung epithelial cells in vitro was 0.25–0.5 mM, which was similar to that known from other body cells and 25-fold higher than that of chloramine T.
Conclusion: The endogenous antiseptic NCT was well tolerated at a concentration of 1% upon inhalation in the pig model. Addition of ammonium chloride in high concentration provokes statistically significant impact on blood oxygenation, which would require adjustment of dose. These results are in accordance with previous clinical studies in man and animals.

Parasitology

P968 A new approach in the diagnosis of intestinal parasites

J.J. Verweij, R.J. ten Hove, T. Schuurman, M. Kooistra, M. van Esbroeck, T. Vervoort, J. van den Ende, L. van Lieshout (Leiden, Groningen, NL; Antwerp, BE)

Background: Twelve years ago molecular diagnostics for the differentiation of *E. histolytica* and *E. dispar* were implemented in Leiden and proved to be highly sensitive and specific. At that time, using PCR only as an additional technique to differentiate cysts and/or trophozoits that were seen by microscopy, it was never anticipated to use PCR as a first line diagnostic. During the following years the isolation of parasitic DNA from faecal samples and PCR techniques, were improved and simplified. Moreover the introduction of real-time PCR made it possible to multiplex different targets into one reaction. These new technical possibilities made it feasible to introduce PCR also for the detection of other intestinal parasites. The first multiplex real-time PCR for the simultaneous detection of the three most important diarrhoea causing protozoa and an internal control proved to be a sensitive and specific method for the detection of *E. histolytica*, *G. lamblia* and *Cryptosporidium* (HGC-PCR). Two studies were performed to define a diagnostic strategy for the implementation of molecular methods in the routine diagnosis of intestinal parasitic infections in general practice patients and in returning travellers and immigrants.
Methods: DNA (n = 350) from faecal samples originating from patients attending their GP with gastrointestinal complaints was tested retrospectively with HGC-PCR. In a second study, PCR analysis was performed on a weekly basis on faecal samples (n = 3591) from returning travellers using HGC-PCR and a Strongyloides PCR. In both studies PCR results were compared with microscopy and anamnestic data.
Results: In both studies, detection rates of the parasitic infections included in the PCR were increased significantly as compared with microscopy. In the GP patients no other pathogenic parasites were detected using microscopy and in the returning travellers additional parasites were found with microscopy in 55 cases only, especially in those travelling to high risk areas.
Conclusions: Multiplex real-time PCR offers a highly sensitive and specific diagnostic alternative for labour intensive microscopy in clinical laboratory practice. Additional diagnostic methods for the detection of parasitic infections that are not included as PCR target can be limited to a selected group of patients.

P969 Optimisation of a flow cytometry protocol for detection of *Encephalitozoon intestinalis*

J. Barbosa, A. Gonçalves Rodrigues, C. Pina-Vaz (Porto, PT)

Microsporidia are spore-forming protozoa considered emerging pathogens in immunocompromised patients. *Encephalitozoon intestinalis* is one of the most important microsporidian human pathogen. The infectious form is a small spore, usually resistant to common water treatment. Its detection is very important but is difficult, time-consuming and requires specialised technicians; phase contrast and/or semiquantitative immunofluorescence-microscopy are the most common used techniques.
Objective: Our main objective was to develop and optimise a specific Flow Cytometric (FC) protocol for detection of *E. intestinalis* and to establish its detection limit; additionally, FC viability studies were undertaken, in order to evaluate the infectious risk.
Material and Methods: A known concentration of *E. intestinalis* spores (Waterborne Inc, USA) were stained with different concentrations of a Alexa Fluor 488 mouse monoclonal antibody (Microspor-FA, A700A488; Waterborne), at varied times (45 min, 1 h30m and 12 hours), at different temperatures (37°C and 25°C) and then analysed in a FACSCalibur cytometer (Becton Dickinson, Canada) at FL1 (525 nm – green fluorescence). Several dilutions (2×10^5 to 1×10^4 spores/ml) were afterwards stained with the optimised antibody concentration and analysed by FC for assessment of the detection limit. Cross-reactions were investigated using both prokaryotic (*Escherichia coli*, *Staphylococcus aureus*) and eukaryotic microorganisms (*Candida albicans* blastoconidia and *Cryptosporidium parvum* and *Giardia lamblia* (oo)cysts). Suspensions with dead spores were stained with 5 μg/ml of propidium iodide (PI, Sigma) (a marker of death with cell membrane lesion) following the staining with the specific fluorescent monoclonal antibody and analysed at FL3 (670 nm-red).
Results: The optimal specific-antibody concentration was 10 μg/ml, incubated overnight at 25°C, in the dark; it provided a clearly separated histogram from autofluorescence. A threshold limit of 5×10^4 spores/ml was established bellow that value, fluorescence was insufficient to allow discrimination. No cross-reactions occurred with bacteria, fungi or parasites. When using the two fluorescent probes simultaneously (specific-antibody and PI) dead spores showed double fluorescence (FL1 and FL3). A new detection method using a FC protocol is now available for the detection of *E. intestinalis*, allowing the simultaneous assessment of viability of the infective forms.

P970 Chagas' disease: evaluation of a rapid immunochromatographic assay for the detection of anti-*Trypanosoma cruzi* antibodies

S. Gabrielli, A. Faraone, S. Bonelli, A. Mantella, M. Strohmeyer, S. Filardo, F. Bartalesi, V. Bejarano, G. Cancrini, A. Bartoloni (Rome, Florence, IT; Camiri, BO)

Objectives: Chagas disease, caused by *Trypanosoma cruzi*, affects 7.6 million of people in Latin America. A survey was carried out to assess its prevalence in two rural Bolivian communities (Bartolo, Chuquisaca Dep., and Casas Viejas, Santa Cruz Dep., Bolivia), and to evaluate the performance of Chagas Quick Test, a new immunochromatographic assay (ICT) to detect anti-*T. cruzi* antibodies.
Methods: 226 subjects were enrolled (121 males, 105 females); the infection was evaluated using a conventional *T. cruzi* IgG ELISA test, the above mentioned ICT, and the microscopic analysis of Giemsa stained thick smears. Individuals showing discordant ICT-ELISA results underwent molecular analyses. DNA was extracted from blood dried on filter paper using Chelex-100® method. *T. cruzi* nuclear DNA was amplified using primers TCZ1 and TCZ2 for the first reaction and TCZ3 and TCZ4 for the nested amplification. Amplicons were sequenced and subjected to GenBank to give the most likely identification.
Results: ELISA was positive in 142 people (62.8%); infection rate increased according to age from 15.3% in 1–9 years old individuals, to 100% in over sixties, independently by sex. No parasitemic individuals were found by hemoscopic analysis. A total of 159 subjects (70.3%) proved positive to ICT; all subjects positive to ELISA had a positive result (relative sensitivity 100%), with an intensely coloured test line. Moreover, 17 individuals negative to ELISA proved positive to ICT, with a very faint test line. The agreement between ELISA and ICT was 92.4% (209/226) (kappa 0.83). Molecular assays confirmed the infection in 4 serologically discordant subjects.
Conclusions: seroprevalence of *T. cruzi* infection in the study population is very high, and increases rapidly with the age, showing that parasite active transmission occurs universally. Negative results obtained by microscopy fit in with the low sensitivity of this diagnostic tool conditioned by the low parasitaemia in chronic infected people. Chagas Quick Test showed an almost perfect accordance with the conventional ELISA. PCR confirmed to be an useful complement to serological methods; it contributed to increase ELISA sensitivity and partially corroborated ICT results, supporting the advice that very faint test lines have to be considered as likely positive. Further investigations are needed to define the infectious status of subjects with discordant serology and negative PCR assay.

P971 Serological screening of Chagas' disease in pregnant immigrant women proceeding from endemic areas in Spain

P. Alonso, A. Rodríguez-Guardado, M. Rodríguez, A. Escudero, E. Vega, P. Leiva, J. Cartón (Oviedo, ES)

Objectives: Maternal-fetal transmission of *Trypanosoma cruzi* generally occurs in 2–12% of pregnant infected mothers. The arrival of pregnant women proceeding from endemic areas to non-endemic countries due to immigration phenomenon make possible the apparition of this diseases in this group of patients. The possibility of congenital infection in pregnant immigrant women in non-endemic areas has been studied only occasionally.
Methods: We determined anti-*T. cruzi* antibodies in all the pregnant immigrant women proceeding from endemic areas attending in obstetric service of Hospital Central de Asturias, a universitary hospital in the Northern of Spain, from 07/03/07 to 23/10/07. The ID-Chagas antibody test (Particle Gel Immuno Assay – PaGIA, DiaMed-ID –) was used as screening assay: red coloured polymer particles are sensitised with three different peptides representing antigenic sequences of *T. cruzi*.
Results: During the period of the study we screened 103 pregnant women (mean age 29 years, limits 17–43). The countries of origin were: Ecuador (32.0%), Colombia (17.5%), Brazil (15.5%), Paraguay (9.7%), Dominican Republic and in a minor percentage Venezuela (5.8%), Argentina (2.9%), Bolivia (2.9%), Cuba (1.9%) and Mexico (0.97%). Sixty patients lived in urban areas and 24 in rural areas. In 20 patients the characteristics of the living place was unknown. Only five patients lived in houses where the reproduction of triatomine bugs is possible. Two patients had family history of Chagas' disease. None patients presented positive antibodies anti-*Trypanosoma cruzi*.
Conclusions: Although the pregnant women arrival of endemic areas, no case of Chagas' disease was detected, probably due to the absence of epidemiological risk factors. Undoubtedly further studies of large samples are necessary to evaluate maternal transmission risk in immigrant population in Spain.

P972 Paediatric Chagas' disease in a non-endemic area

T. Juncosa, V. Fumadó, M. Sanllorente, A. Aguilar, R. Pino (Barcelona, ES)

Objectives: During last years, increasing migration from Central and South America, the endemic area of Chagas Disease, has introduced among our paediatric population some patients infected by *T. cruzi*, infected either in their origin country or in ours, via vertical transmission from their infected mothers. The objective of this study is to describe the cases of children with Chagas Disease attended at our Imported Pathology Unit during the last four years (2003–2007).
Methods: All patients coming from endemic areas and newborns from Chagas Disease seropositive pregnant women, were studied by two ELISA tests (Bioelisa Chagas BiokitR with recombinant antigens and in-house ELISA with complete antigens). Patients with available sample (59) were also screened by nested PCR (TCZ3/Z4). Confirmed cases received Benznidazol treatment (0.7 mg/Kg/day during 60 days).
Results: Screening was performed to 155 patients, aged one day to 13 years old (110 immigrants and 45 born in Spain). Ten of them were seroreactive in both ELISA tests (6.45%) and we had enough blood from five of them for PCR tests, which were positive for all samples. Vertical transmission was demonstrated in two children born in our country, one from a Bolivian mother and the other from an Argentina's one. The eight immigrated children were born in Bolivia. Follow up is in course in eight out of the ten seroreactive patients (two of them didn't continue attending our hospital) in order to establish the effectiveness of treatment. Negative PCR and decreasing specific antibodies have been demonstrated in all studied patients.
Discussion: Our results demonstrate a seroprevalence for *T. cruzi* infection of 7.2% (8/110) among the paediatric immigrated population coming from Latin America, and an incidence of congenital infection of 4.4% (2/45). Both percentages are high enough to encourage serologic screening for Chagas Disease to all children coming from Latin America, mainly from Bolivia. Post treatment serologic control must continue until antibodies level become negative. We have demonstrated titles decrease, but negativisation has not been assumed in any case.

P973 Chagas' disease among Latin American immigrants in Madrid. A serological survey

N. Portocarrero, M. Baquero, M. Gutierrez (Madrid, ES)

Introduction: Chagas' disease, caused by infection with *Trypanosoma cruzi* is a significant health problem in Latin American, where an estimated sixteen to eighteen million people are infected. Outside of endemic regions, Chagas' disease may be transmitted through the transfusion of infected blood components, congenital infection and organ transplantation.
Objective: To determine the sero-prevalence of antibodies to *T. cruzi* in a community sample of Latin American immigrants to Madrid, Spain.
Methods: Eligible subjects were born in South America, Central America or in Mexico. Participants were attending a variety of medical clinics at the hospital Carlos III, Madrid, Spain. Serum samples were collected from January 2005 to November 2007. Antibodies to *Trypanosoma cruzi* were identified using a commercial screening EIA method (Biokit, Spain). Specimens that were repeatedly reactive by EIA were analysed by an indirect immunofluorescent assay, (Biocientífica S.A, Argentina)
Results: A total of 588 serum samples were studied. The geographic distribution of the patients was: 274 Ecuador (46.6%), 88 Colombia (15%), 82 Bolivia (14%), 31 Peru (5.3%), 28 Brazil (4.7%), 18 Dominican Republic (3%), 11 Venezuela (1.7%), 8 Argentina (1.4%), 8 Mexico (1.4%), 6 Chile (1%) and 34 other countries of Latin American (5.9%).
Thirty patients out of 588 (5.1%) were considered reactive for antibodies to *T. cruzi* by EIA. Indirect immnunofluorescent assay was performed in 26/30 reactive samples by EIA, being 20 positive.
Twenty five reactive samples corresponding to 82 patients (30.5%), coming from Bolivia, 3/274 (1.1%) from Ecuador, and 2/5 (40%) from Guatemala.
Conclusions: High rates of *T. cruzi* seropositive patients among Latin American immigrants underscore the importance of screening in this population to prevent transmission by blood transfusion or organ transplantation as well as congenital infection.
The Chagas antibodies EIA showed improved sensitivity over the Chagas indirect immnunofluorescent assay (IFA).

P974 Chagas' disease in Latin American immigrants in Valencia, Spain

P. Segarra, M. García-Rodríguez, I. Jiménez, R. Sanz, X. García-Fabra, V. Abril, T. Fraile, C. Parada, E. Ortega (Valencia, ES)

Introduction: Chagas Disease is caused by *Trypanosoma cruzi*. Approximately 70% to 80% of infected individuals remain in the indeterminate form throughout their lives, whereas as many as 20% to 30% develop into a cardiac form (arrhythmia, heart failure, ...) or a digestive form (megaesophagus, megacolon). The only treatment available nowadays in Spain is Benznidazole.
Objectives: To analyse epidemiological and clinical features of adults patients with Chagas Disease.
Methods: Since January 2005 until November 2007, we tested sera from Latin American adults coming to a Tropical Disease consultation, or travelers with an epidemiological risk for *Trypanosoma cruzi* infection. Immunological diagnosis was made using commercially available serological tests: Recombinant ELISA (BioElisa Chagas, Biokit S.A®, or Dade Behring®), and IFI (MarDxDiagnostic®).
Case definition: Any patient with epidemiological risk factors and two or more different serological tests positive. Clinical and epidemiological

review, physical examination, HIV serology, chest radiography, electrocardiography (ECG), echocardiography, and radiographic contrast study of esophagus and colon were performed.
Results: Thirty six cases of Chagas disease have been identified, all of them Latin American immigrants. Mean age 40.17 years (23–65). Gender: 75% women, 25% men. Polymerase chain reaction was available in 20, and positive only in 2. Most of the cases (86%) were from Bolivia. Twenty nine (80%) were indeterminate forms, 4 patients (11%) had a chronic cardiac form, 2 patients (5%) a mixed form, and 1 (2%) a chronic digestive form. A forty four years old woman died because of dilated cardiomyopathy and complex ventricular arrhythmias. The other abnormal ECG findings were sinusal bradycardia, right bundle-branch block, complete A-V block, left anterior fascicular block. All patients were HIV seronegative. Treatment with Benznidazol was started in 8 patients.
Conclusion: Chagas Disease is an emergent disease in Europe because migratory movements. Most of our patients are asymptomatic women from Bolivia, however, about 20% of the patients have chronic forms that can progress to heart failure, and can require intensive and multidisciplinary care.

P975 Prevalence of oral trichomoniasis in patients with periodontitis and gingivitis using PCR and Direct Smear

A. Athari, L. Soghandi, A. Haghighi, B. Kazemi (Tehran, IR)

Objective: *Trichomonas tenax*, a commensal flagellated protozoan, inhabits in human oral cavity. This parasite is cosmopolitan and frequently found in patients with poor oral hygiene and advanced periodontal disease. There is only one published study that rebound the prevalence of this parasite in Iran. This PCR based study compared the prevalence of oral trichomoniasis in patients with oral diseases and a healthy control group.
Methods: From May 2006 to April 2007, the subgingival dental plaques of 160 patients with gingivitis or periodontitis and 160 controls who attended to Dental School of Shahid Beheshti Medical University, Iran were taken and examined by wet mount smear, and Giemsa staining. Likewise, a PCR protocol was developed for specific detection of *T. tenax* using a pair of primers designed for its 18S rRNA gene.
Results: Thirty three (20.6%) of patients were PCR positive while 28 (15.5%) were diagnosed using wet preparation and Giemsa staining. In the other hand, 2 (1.9%) of control group were identified positive by PCR procedure. The prevalence of oral trichomoniasis in our study (20.6%) was compatible with many other published reports which mostly has ranged from 12%-32%.
Conclusion: The study revealed dependence between the frequency of occurrence of *T. tenax* and the state of periodontitis. The present PCR procedure could provide a simple and rapid detection method of *T. tenax* in dental plaque.

P976 Real-time PCR in diagnostics of *Trichomonas vaginalis* infection

M. Sviben, G. Vojnovic, I. Kolcic (Zagreb, HR)

Objective: *Trichomonas vaginalis* is the most common parasitic cause of sexually transmitted infection in the world. Methods used for the laboratory diagnosis of *T. vaginalis* infection include microscopic examination of wet mount preparations, culture and more recently polymerase chain reactions (PCR). The objective of this study was to determine the prevalence of *T. vaginalis* infection in men tested at the Parasitology department of the Croatian National Institute of Public Heatlh between July and October 2007. A comparison of real-time PCR with culture and wet-mount microscopy in the diagnosis of trichomonosis was also performed.
Methods: Urine samples from 151 men were tested for *T. vaginalis* using culture and real-time PCR. One part of urine sediment was inoculated in Diamond's medium and examined for motile organisms after 24, 48 and 72 hours. From other part of sediment DNA was isolated using a spin column kit (High Pure PCR Template Preparation Kit; Roche Diagnostics GmbH). Real-time PCR was applied for detection of *T. vaginalis* DNA using a TaqMan Universal PCR Master Mix kit (Applied Biosystems). To rule out the presence of PCR inhibitors in the individual patient specimens, an internal control kit (TaqMan Exogenous Internal Positive Control Reagents; Applied Biosystems) was used. The amplification and detection were performed using 7500 Real Time PCR System machine (Applied Biosystems).
Results: Out of the 151 urine samples tested, 2 were positive by culture and 2 more (4 altogether) by PCR. The prevalence of *T. vaginalis* infection in male study population according to PCR was 3%. Real-time PCR also exhibited greater sensitivity than culture did (100 vs. 50%).
Conclusions: Despite all the efforts invested in development of better diagnostic tests for trichomonosis, PCR is not commonly used. The main reason is that *T. vaginalis* infection is not perceived as a significant public health problem. However, this perception should be changed based on recent studies suggesting a role of *T. vaginalis* in adverse pregnancy outcome and HIV transmission. A real-time PCR has immediate and important implications for diagnostic testing in the microbiology laboratory. The enhanced sensitivity, ease of performance and speed of this technology make it an appealing alternative to conventional methods which have been used for many years.

P977 Prevalence of hydatid cyst in a slaughter-house in Iran: a ten-year survey

H. Tavakoli, N. Jonaidi Jafari, M. Izadi, M. Parsa (Tehran, IR)

Objectives: Parasitic diseases are a major group in zoonosis, in which hydatidosis has a special situation prevalence of hydatid cyst in a region's animals in dangerous that could lead to prevalence of the disease in man. This will also increase inurn, disadvantages such as removing, contaminated organs of animals (e. g. liver and lung), decrease products like milk, weigh, wool, quality of meat plus economic expenses. Evaluation and determining of health and economic importance of each disease would be the first step in any prevention and control programs.
Methods: In this retrospective survey, slaughtered animals (cow, sheep) were studied in respect to hydatid cyst infection according to kind of animal, year, and season in a ten-year period (1996–2005) in Semnan's slaughter-house.
Results: The findings of this study showed that 13–25% liver and 15.97% lung were confiscated (the total no. of slaughtered animals was 359716 include 39698 cow and 320018 sheep). Based on the results 37.43% of livers and 51.18% lungs were infected by hydatid cyst. The mean of liver and lung infection in cow was 4.84% and 4.41% respectively. This rate was 5.05% and 6.84% in sheep. On the basis of season the most infection rates in both animals were observed in turn in autumn and winter. The estimated economic damage due to omission of infected organs, only by hydatidosis in this period was 1667720000 Rails.
Conclusion: The results of the study, from the epidemiological aspect, could be a confident starting point, in preventive and controlling programs of this important parasitic disease. Due to zoonosis the presented proposals would decrease the human hydatidosis.

P978 Bursts of trichinellosis in a Romanian industrial area

R. Neghina, A.M. Neghina, I. Marincu, L.D. Giurgiu, L.M. Leahu, R. Moldovan, I. Iacobiciu (Timisoara, RO)

Objectives: To overview and analyse epidemiologically all the trichinellosis cases diagnosed during an endemic decade in an industrial area from Hunedoara County, situated in the central-western part of Romania.
Methods: We retrospectively extracted data from the medical records of 353 patients hospitalised during the period 1996–2005 at "Dr. Al. Simionescu" Hospital from Hunedoara, Department of Infectious Diseases. There have been analysed the following particularities

regarding the study group: age, gender, inhabitance area, year and season of hospitalisation and profession.
Results: Most of the patients (27.47%, n = 37) were in the age group of 10–19 years old; 198 patients (56.09%) were women; 233 patients (66.01%) lived in the urban areas among whom 195 patients were inhabitants of Hunedoara town; 1997 was the year with the largest number of the cases (32.58%, n = 315); 55.24% of the patients were hospitalised during the winter; 42.66% were unemployed people.
Conclusion: Hunedoara town and the surroundings belong to a heavy industrial area in decline where a lot of people are poor and unemployed. There is also a large gipsy community living in unsanitary conditions, eating uninspected pork products. This facts can explain the frequent bursts of trichinellosis that occur in this area especially within the group mentioned above. Most of the cases were diagnosed in winter when, according to regional food habits, a lot of pigs are slaughtered.

P979 Subtyping *Blastocystis hominis*: is subtype 2 responsible for asymptomatic infections?

F. Dogruman Al, H. Dagci, H. Yoshikawa, Ö. Kurt, M. Demirel (Ankara, Izmir, TR; Nara, JP; Manisa, TR)

Objectives: *Blastocystis hominis* is probably the most common eukaryotic organism in the intestinal tract of humans, with increasing reports indicating its presence in patients with gastrointestinal and dermatological manifestations. However, little is currently known about its pathogenesis in human infections. Isolated both from humans and various animals, this interesting protozoon has numerous known subtypes and the relation between these subtypes and its pathogenesis is yet under research. The aims of this study were to identify *B. hominis* isolates in both adult and paediatric patients with and without symptoms in two hospitals in Manisa City, Turkey, and subtype them to identify any correlation between the reported symptoms and subtypes.
Methods: Stool samples of the individuals were examined with routine O&P examination and the presence of *B. hominis* was confirmed with the examination of trichrome stained smears. All positive samples were inoculated in Robinson's medium and a total of 92 samples were included in the study. The individuals were grouped according to having any related symptoms or not. DNA was extracted from each sample using the QIAamp DNA Stool Mini Kit (QIAGEN, Hilden, Germany)according to the recommendations of the manufacturer, followed by genotyping with PCR using seven different primers. Chi-square testing was applied for the statistical analyses.
Results: Microscopic examination of the stool samples of symptomatic cases revealed that only 11 (18.6%) were *B. hominis*-positive. Subtype 3 was by far the most common (n = 31; 55.4%) *Blastocystis* subtype and Subtype 2 was found more common in asymptomatic cases with a statistical significance ($p<0.05$). No other significant relation was detected with other subtypes in the study.
Conclusion: Concordant with the results of the previous studies, Subtype 3 isolates were found to be most common in Manisa, as well. Further studies conducted with cases from different regions are needed to confirm the present relation with Subtype 2 and asymptomatic infections.

P980 Prevalence of *Giardia intestinalis lamblia* among children with allergies from Saint-Petersburg, Russia

M. Suvorova, E. Tarasova, E. Kazennova, N. Rodionova, R. Al-Shehadat (Saint-Petersburg, RU)

Odjectives: The percentage of allergic children in Russian megalopolis is increasing each year. It's considered that about 70% of children in Saint-Petersburg have various kinds of allergies.. From the previous studies we see that there are certain association between the *Giardia intestinalis* detection in stool specimens and clinical manifestations of allergies. In Saint-Petersburg 43–45% of children with allergy symptoms from atopic dermatitis to bronchial asthma were infected with *Giardia intestinalis*. However the possibility that allergies might be associated with other parasites (*Ascaris lumbricosis*, *Eterobius vermicularis*, *Trichinella spiralis*, *Dirofilaria immitis*) was not investigated. Therefore the goal of this study is to find connections between allergy symptoms, *Giardia intestinalis* and helminthes.
Materials and Methods: 40 children under 12 years old with allergy were involved in this study. 20 of them were positive for *Giardia intestinalis* and 20 were negative. For *Giardia intestinalis* detection we used traditional microscopy and PCR.
Feaces from all children were examined by PCR and microscopy for helminthes identification.
DNA from faeces were extracted with "DNA-express" kit (Lytech, Russia). PCR was performed with specific primers, and detected by gel-electrophoresis in 1.5% agarose.
Result: In all 40 cases microscopy analysis was negative for helminthes and for *Giardia intestinalis*. Patients with *G. intestinalis* group have been tested positive by PCR at least twice.
In *G. intestinalis* positive group (20 children) 6 patients were detected with *T. spiralis* (30%), 5 with *A. lumbricosis* (25%), three cases with *D. immitis* (15%) and 2 cases with *E. vermicularis* (10%).
In *G. intestinalis* negative group (20 children) one was detected with *T. spiralis* (5%), 3 – *D. immitis* (15%). *A. lumbricosis* and *E. vermicularis* were not detected.
Conclusion:

1. Children infected with *Giardia intestinalis* are more predisposed to helminthes contamination.
2. Prevalence of *Trichinella spiralis*, *Ascaris lumbricosis*, *Dirofilaria immitis*, *Eterobius vermicularis* among allergic children was high.
3. The only helmint that was found in same percentage from both groups of children was *Dirofilaria immitis*. The only helminthes that is not transmitted through the intestinal tract.

P981 Preliminary analysis of the molecular phylogenetics of *Toxocara canis* (Nematoda: Ascaridoidea) using nuclear ribosomal second internal transcribed spacer sequences

A. Rodriguez-Morales, R. Barbella-Aponte, M. Arria (Caracas, VE; Valencia, ES)

Objectives: Toxocariasis is a zoonotic disease caused by *Toxocara canis* and *T. cati*. Human is their paratenic host. Although many clinico-epidemiological aspects have been studied in almost 60 years after the discovery of human disease, many biological and molecular aspects are still lack of knowledge and research. After a careful review of literature we did not found any study describing the phylogenetics of *Toxocara* using any molecular marker.
Methods: For these reasons, nuclear internal transcribed spacer 2 (ITS2) rDNA sequences were used for the first molecular phylogenetic analysis and tree of five *Toxocara* species. ITS2 rDNA sequences were already available from GenBank (accession numbers AB110034, AB110033, EU189085, AM231609 and AB027152), corresponding to *T. canis*, *T. cati*, *T. vitulorum*, *T. malaysiensis* and *T. tanuki*. Phylogenetic analysis was made after aligned these sequences using GeneDoc 2.7 (Figure), using the method of Maximum Parsimony and the bootstrap test for phylogeny with MEGA 4.
Results: As expected, *T. canis* and *T. cati* ITS2 alleles are monophyletic, as well *T. malaysiensis* with *T. vitulorum* (Figure). As expected also, we observed a high nucleotide diversity (p = 0.705825; Tajima test = 0.461359) between the studied species.
Conclusions: The nuclear ITS rDNA sequence has been extensively used to define genetic markers for different species of nematodes and the aims of this study were to use the ITS2 to investigate the levels of genetic variation within *Toxocara* and generate a first phylogenetic tree (Figure). If there are normal levels of gene flow between populations (or species), these populations are likely to be similar in their overall genetic characteristics, and genes for important characteristics are likely to spread easily. ITS2 of other *Toxocara* species should be included in further analysis (eg. *T. genettae*, *T. lyncis*, *T. vincenti*, among others), to

better define the evolutionary relationships and phylogeny of the genus *Toxocara*.

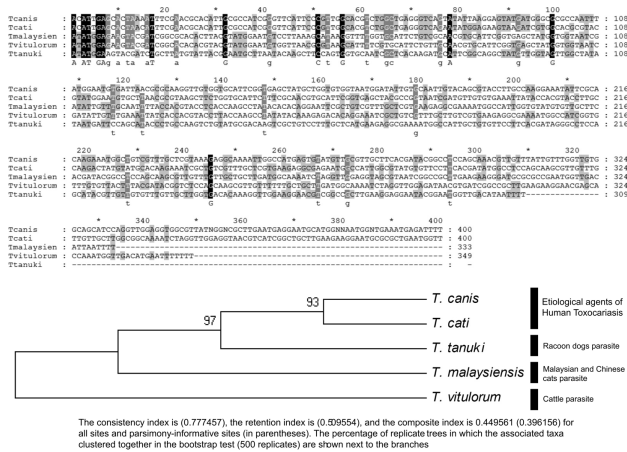

Figure. Multiple sequences alignment (upper) and evolutionary relationships of *T. canis* and other spp. (lower). The consistency index is (0.0777457), the retention index is (0.509554), and the composite index is 0.449561 (0.396156) for all sites and parsimony-informative sites (in parentheses). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (500 replicates) are shown next to the branches.

P982 Is multiple-stool-specimen ova and parasite examination necessary?

F. Grünbaum, C. Muñoz, R. Morató, E. Giménez, R. Soler, T. Llobet, P. Coll (Barcelona, Reus, ES)

Objectives: We performed a retrospective analysis of 12,862 ova and parasite (OP) examinations of stool specimens from 8109 patients visited at Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, between 2004 and 2006 to evaluate the utility of such tests in multiple, independently-collected stool specimens.

Methods: Multiple-specimens from a single patient were considered related to the same clinical episode if collected within 14 days. A series was thus defined as specimens of the same clinical evaluation. A positive result was defined as the presence of pathogenic OP in stool specimen. Presence of *Trichomonas hominis*, *Chilomastix mesnili*, *Endolimax nana* and *Entamoeba coli* were also considered positive. A second or third specimen was considered positive for a parasite only if the previous specimens were negative. As a positive result for another parasite in the same series was considered a further positive result, a single series could have more than one positive result. Standard parasitological techniques were used.

Results: Of the 12,862 specimens submitted, 10,086 corresponded to single-specimen series, 1942 to 2-specimen series and 734 to 3 or more specimen series. To evaluate the utility of multiple-specimen examination we focused on series of at least 3 specimens. The first specimen collected was diagnostic in 49.15% (29 of 59) evaluated cases. The examination of 2 specimens increased sensitivity to 79.66% (47 of 59). The third specimen collected provided additional information in 12 cases (20.34%). Information provided by the first specimen, in comparison with the second, was not statistically significant ($p = 0.074$), although a tendency was observed. Differences between information provided by the first and third specimen were statistically significant (0.006). Differences between second and third specimens were not statistically significant ($p = 0.352$).

Conclusions: These data suggest that 2 specimens per series should be studied in order to achieve sensitivity closest to 80%. As the difference in information provided by the second and third specimens is not significant, a third specimen is not needed.

P983 Anti-giardial activity of carvacrol, thymol and eugenol

M. Machado, C. Cavaleiro, L. Salgueiro, J. Poiares-da-Silva, J.B. Custódio, M.C. Sousa (Coimbra, PT)

The protozoan parasite *Giardia lamblia* is recognised as one of the most important non-viral infectious agents causing diarrhoeal illness in humans around the world. Current therapy against *G. lamblia* infection (giardiasis) is unsatisfactory due to high incidence of undesirable side effects and a significant failure in clearing parasites from the gastrointestinal tract. Consequently, new compounds are being screened for antigiardial activity, namely essential oils and their pure compounds, which revealed on previous studies important antibacterial, antifungal and antiparasitic activity. In the present work, we studied the effects of pure phenolic-compounds such us carvacrol, eugenol and thymol on *G. lamblia* growth and adherence. Culture trophozoites of WB strain (ATCC 30957) were incubated in growth medium with different concentrations of phenolic compounds for 48 h at 37 °C under anaerobic conditions. The concentrations that inhibit the growth at 50% (IC50) were determined by total cell counting. To study the effects on *Giardia* adherence, an inoculum of 5×10^4 trophozoites was exposed to pure phenolic-compounds at IC50 concentrations during 7 h at 37°C in Keister medium without serum. The number of unattached and attached cells was determined microscopically using a haemocytometer (Neubaeur cell counter chamber) and the results were expressed as percentage of attached trophozoites in relation to the total number of *Giardia* cells reached from each assay. The experiments were performed in duplicate and in three independent assays ($n = 3$), and the analysis of variance (ANOVA) was used. The growth of *G. lamblia* was significantly inhibited by thymol, carvacrol and eugenol. The most active compound was thymol (IC50 = 47 μg/ml), followed by carvacrol (IC50 = 50 μg/ml) and eugenol (IC50 = 131 μg/ml). The tested phenolic compounds inhibit *G. lamblia* trophozoites adherence ($p<0.001$) from the first hour of incubation. The total cell number (attached and unattached cells) after 7 hours of incubation was unaffected by eugenol, but was decreased by carvacrol (30%, $p>0.05$) and thymol (50%, $p<0.01$). These results suggest that carvacrol, thymol and eugenol have antigiardial activity inhibiting the cells growth and attachment, inducing cell death. Therefore, these compounds seem to have potential for use as therapeutic agents against giardiasis.

This work was supported FCT POCTI (FEDER).

P984 Effects of phenolic-rich essential oils on the morphology and adherence of *Giardia lamblia* trophozoites

M. Machado, L. Salgueiro, J. Poiares-da-Silva, C. Cavaleiro, M.C. Sousa (Coimbra, PT)

Attachment of *Giardia lamblia* trophozoites to enterocytes is essential for colonisation of the small intestine and is considered a prerequisite for parasite-induced enterocyte dysfunction and clinical disease. *G. lamblia* trophozoites can also attach to in vitro cultured cells as well as to glass, plastic and to a variety of artificial substrates. Considering that inhibition of its attachment may have therapeutic potential, it was of interest to study the ability of essential oils to inhibit the *G. lamblia* adherence.

In previously studies we have showed that phenolic rich essential oils inhibit the growth of *G. lamblia* in vitro. In the present work, we evaluated the effects of essential oils on morphology and adherence of *G. lamblia* trophozoites. Essential oils were obtained by hydrodistillation from fresh plant material and analysed by GC and GC-MS. Constituents were identified from their retention indices on two different phases GC columns (polydimethylsiloxane and polyethyleneglycol) and from their mass spectra, which were compared with reference data. An inoculum of 5×10^4 trophozoites (WB strain, ATCC 30957) was exposed to essential oils at concentrations that inhibit the growth at 50% (IC50) during 7 h at 37 °C. The morphological alterations were studied by optical and transmission electronic microscopy. The number of unattached and attached cells was determined microscopically using a haemocytometer and the results were expressed as percentage of attached trophozoites in

relation to the total number of *Giardia* cells reached from each assay. The experiments were performed in duplicate and in three independent assays (n = 3), and statistically, the analysis of variance (ANOVA) was used.
The essentials oils from *Thymus zygis* ssp. *sylvestris*, *Thymbra capitata*, *Origanum virens*, *Lippia graveolens* and *Syzygium aromaticum* inhibit *G. lamblia* trophozoites adherence (p<0.001) since the first hour of incubation. The main morphological alterations promoted by essential oils were deformations in typical trophozoite appearance, such as modifications on the cell shape, alterations in plasma membrane, presence of precipitates in the cytoplasm and intracellular clearing. The results suggest that these phenolic-rich essentials oils have anti-giardial activity modifying the attachment ability and promoting cell death by a lyses process, having potential for use as therapeutic agents against giardiasis.
This work was supported FCT POCTI (FEDER).

P985 High Prevalence of *Giardia* in dogs from Portugal: genetic characterisation of isolates by sequencing analysis of beta-giardin gene locus

J. Machado, M. Machado, P. Ramalho, J. Poiares-da-Silva, M.C. Sousa (Coimbra, Braga, PT)

Human giardiasis is considered a zoonotic infection, although the role of animals in the transmission to humans is still unclear. Molecular characterisation of cysts of human and animal origin represents an objective means to validate or reject this hypothesis.
Some animal derived isolates appear to be similar or identical to human derived genotypes while others represent unique genotypes that seem to be host-specific. When considering the zoonotic potential of each genotype, the Assemblage A and B are believed to represent a major risk for human health since both appear to be infective to a wide range of wild and domestic host species. In the present study, isolates of *Giardia* were genetically characterised by using PCR-based procedures to determine the occurrence of potentially zoonotic genotypes of *G. lamblia*.
Faecal samples (n = 37) were obtained from dogs in kennel situations in north of Portugal. The parasitological study was performed by microscopy observation (direct examination and after concentration by Copropack S.A.F, Biomedics, S.L.) and *G. lamblia* coproantigen detection was performed by immunocromatografic method (Sick *Giardia*/simple *Giardia*, Operon). The β-giardin gene locus was amplified by nested-PCR and PCR products were sequenced with dRodamina Terminator Cycle Sequencing kit. The reading was performed using an ABI PRISM 310 automatic DNA Sequencer and the obtained sequences were aligned with those available in Genbank using Clustal X program. Sequence accuracy was confirmed by two-directional sequencing.
A total of fourteen faecal samples were positive to *Giardia* cysts (51.8%), one for Isospora sp. (3.7%), four to *Ancylostoma* sp. (14.8%), two to *Toxocara canis* (7.5%) and one to *Capillaria* spp. (3.7%). The *Giardia* antigen detection test was positive for 13 dog faeces samples (48%). Of 16 *Giardia* cysts and/or antigen positive faeces, 12 samples were successfully amplified at the beta-giardin locus gene. The sequencing analysis showed that the assemblage A was detected in eight samples. This is the first genetic characterisation of *Giardia* isolates in dogs from Portugal. The results confirmed the high prevalence of *Giardia* in dogs and showed that the zoonotic Assemblage A was common in this domestic animal. The results demonstrate that a significant proportion of dogs in north of Portugal harbour zoonotic *Giardia* and should thus be considered a potential reservoir for infection in humans.
This work was supported FCT POCTI (FEDER).

P986 Albendazole versus praziquantel in the treatment of neurocysticercosis: a meta-analysis of comparative trials

D. Matthaiou, G. Panos, E. Adamidi, M. Falagas (Athens, GR)

Objective: We investigated the role of albendazole and praziquantel in the treatment of patients with parenchymal neurocysticercosis by performing a meta-analysis of comparative trials of their effectiveness and safety.
Methods: We performed a search in the PubMed database, Cochrane Database of Controlled Trials, and in references of relevant articles. Six studies were included in the meta-analysis.
Results: Albendazole was associated with better control of seizures in comparison with praziquantel in the pooled data analysis using a random effects regression model of the incidence of seizure control [patients without seizures/(patients X years at risk)] [156 patients in 4 studies, point effect estimate =4.94, 95% confidence interval 2.45–9.98]. In addition, albendazole was associated with better effectiveness regarding the total disappearance of cysts in comparison with praziquantel (335 patients in 6 studies, random effects model, OR=2.30, 95% CI 1.06–5.00). There was no difference between albendazole and praziquantel regarding adverse events and development of intracranial hypertension due to the administered therapy.
Conclusion: A critical review of the available data from comparative trials suggest that albendazole is more effective than praziquantel regarding clinically important outcomes in patients with neurocysticercosis. Nevertheless, given the relative scarcity of trials, more comparative interventional studies, especially randomised controlled trials, are required to draw a safe conclusion about the best regimen for the treatment of patients with parenchymal neurocysticercosis.

P987 Assessment of parasitic and microbial infections in vegetables using different washing methods

A. Khosravi, E. Asadollahy, A. Armani (Ilam, IR)

Objectives: Vegetables are very important part of the dairy food. Contamination can occur in vegetables particularly if there is a poor sanitation condition such as what in present in some part of Ilam province in Iran. Both microbial and parasitic infection can be found on vegetables if the washing method is not accurate.
Methods: 180 vegetable samples were randomly selected from retailer in different areas of the Ilam city. Vegetables were rinsed with tap water thoroughly keeping the water for examination while the sample treated with detergent and hypochlorite separately and the water kept again for examination purposes. Formalin-ether concentration was applied comparing to sedimentation and direct microscopy
Results: The parasitic infections were observed in more than 40% of samples while the microbial infection in more than 70%. The parasitic infections were reduced after treating with detergent but this was not statistically significant. No significant decrease was observed for the microbial infection after washing with soap while it was significant after treating with hypochlorite. *Giardia lamblia* (43%), *Ascaris lumbricoides* (5.6%), *Taenia* (8%), *Entamoeba coli* (7.8%), other Amoeba (7%) and *Trichucephalus* (5%) were the most prevalent infection in samples.

P988 Outbreak of cyclosporiasis in Istanbul, Turkey, during an extremely dry and warm summer

M. Ozdamar, S. Turkoglu, E. Hakko (Kocaeli, TR)

Objectives: *Cyclospora cayetanensis* is an important agent of traveler diarrhoea in developed countries and was responsible for numerous foodborne outbreaks worldwide. We describe a *Cyclospora* outbreak in a region between Istanbul and Kocaeli during a very warm and waterless summer.
Methods: 286 patients with diarrhoea were admitted to Anadolu Medical Center outpatient clinics during July-August 2007. Stools are investigated routinely for coccidian parasites in the microbiology laboratory of the Anadolu Medical Center, especially in the summer months. Modified acid-fast stain and careful microscopic examination (including UV light analysis) are performed after Para Pak (Meridian Diagnostics) concentration. *C. cayetanensis* specific polymerase chain reaction (PCR) based on nucleotide sequences for ITS-1 region was performed in microscopy positive stools.

Results: *C. cayetanensis* oocysts were found to be positive in the stool of 16 patients. *C. cayetanensis* (7 female, 9 male, median age is 41.94 plus/minus 10.0). *C. cayetanensis* DNA were found to be positive by PCR in only 12. The diarrhoea was persistant in most of these patients. No cases were detected in June and September.
Conclusion: *Cyclospora* prevalence was significantly higher compared with 2006 season (data not shown). The food histories showed that some patients had eaten a green salad. There were additional cases that we could not have the possibility to further analyse. All the patients were successfuly treated with trimetoprim-sulfametoxazol (TMP/SMX 160/800 mg bid). *C. cayetanensis* infection is more prevalent in Turkey during summer as reported previously. The laboratories should always consider performing modified acid-fast staining (very efficient for this purpose) to diagnose this parasite in acute or sub-acute diarrhoea cases. A single-step PCR is not as sensitive as the conventional method but serve to further analyse the genome of the parasite. An extremely dry summer came after an extremely warm winter in 2006–2007 season. This deserves further speculation to correlate with outbreaks.

P989 *Fusarium oxysporum* and free-living amoebae

E. Cateau, C. Goncalves, J.M. Berjeaud, C. Imbert, M.H. Rodier (Poitiers, FR)

Objectives: *Fusarium oxysporum* is responsible for infections in immunocompromised patients. Some authors have identified hospital water distribution systems as reservoirs of *Fusarium* species. In these systems, amoebae of *Acanthamoeba* and *Hartmannella* genus are also often recovered and it is known that these protozoa can influence the growth of other microorganisms as bacteria or yeasts. We have investigated the potential interactions between *A. castellanii* or *H. vermiformis* and *F. oxysporum* (isolated from a cornea).
Methods: *A. castellanii* ATCC 30234 or *H. vermiformis* ATCC 50256 trophozoites (5.10^5/ml) were incubated with 5.10^4/ml conidia of *F. oxysporum* (MOI = 0.1). The coculture was incubated in PBS at 27°C during 24, 48 or 72 h. Controls were realised by incubating fungus in PBS alone. After incubation and amoebae lysis, dilutions of this lysate were plated on Sabouraud agar to determine CFU.
Trophozoites (5.10^5/ml) of each amoebae strain were incubated during 24, 48 or 72 h in PBS at 27°C. Amoebae were pelleted and *F. oxysporum* conidia (5.10^4/ml) were cultivated in the resultant supernatant. After 24 or 48 h of incubation, each suspension was plated on Sabouraud agar and CFU were numbered. The germinative potential of *F. oxysporum* conidia was microscopically determined at 4, 8, and 24 h.
Results: In cocultivation experiment, the presence of each free living amoeba led to an increase of *F. oxysporum* growth whatever the duration of incubation.
The contact (24 or 48 h) of *F. oxysporum* with the amoebae supernatants promoted an increase of the number of fungal CFU, compared to *Fusarium* growth in PBS alone. The conidia germination, microscopically verified, occurred only with the supernatant of *H. vermiformis* after 24 h of incubation. No germination was observed after incubation in PBS or in *A. castellanii* supernatants.
Conclusion: The results of this preliminary study indicate that the presence of free living amoebae in the same environment could lead to an increase of the *F. oxysporum* development. Moreover, the *A. castellanii* and *H. vermiformis* trophozoites used here can release substances able to favour the growth of this fungus. So, in hospital water taps, a special attention should be paid to the presence of free living amoebae, which can not only promote bacterial growth, but also development of fungal pathogens.

Molecular diagnosis of viruses

P990 Contribution of RSV and hMPV to patients with influenza-like infections during 2006–2007 season in northern Greece

G. Gioula, A. Melidou, M. Exindari, D. Chatzidimitriou, V. Kyriazopoulou-Dalaina (Thessaloniki, GR)

Background: Every year, during influenza season, many different viruses (such as RSV and the newly discovered hMPV) co-circulate, infecting individuals in the community.
Objectives: The aim of this study was to determine the contribution of RSV and hMPV to influenza-like illness (ILI) cases during 2006–2007 influenza season in N.Greece.
Materials and Methods: One hundred and twenty-nine pharyngeal swabs (129) from patients presented as ILI infections during the last influenza season (2006–2007) were examined at the National Influenza Centre by conventional and molecular techniques for influenza viruses, RSV and hMPV.
Results: Of the 129 patients examined, 52 (40.3%) were laboratory confirmed influenza (AH3) infections, 7 (5.4%) were laboratory confirmed RSV infections and 8 (6.2%) were laboratory confirmed hMPV infections. Five of the seven RSV cases appeared in children younger than 3 years old. Co-infections (RSV and A(H3) influenza viruses) were detected in two cases, concerning adults. From the 8 hMPV cases, five were children <9 years old and three were young adults (<25 years old). Co-infections (hMPV and A(H3) influenza viruses) were detected in two cases, concerning both children and adults. 2006–2007 influenza season started in January 2007 and lasted till the end of March, peaking in February. RSV was detected in the beginning and the end of this season, while hMPV was circulating during the whole period.
Conclusions: As RSV and hMPV infections mimic influenza, it is common to be clinically confused, especially in children. Including RSV and hMPV in the laboratory diagnosis of ILI cases distinguish the contribution of these viruses in such infections.

P991 Multiplex MLPA assay for simultaneous detection of 6 viral agents causing central nervous system infections

P.F.G. Wolffs, C.A. Bruggeman, C. Vink, G. Simons, A.J. van den Brule (Maastricht, Eindhoven, NL)

Objectives: Molecular DNA-based diagnostics are increasingly being used for detection of infectious agents in cerebrospinal fluids. However, the increasing list of targets and the small sample volume are challenges that demand an improved molecular diagnostic approach. Therefore, in this study we have developed a multiplex ligation-dependent probe amplification (MLPA) assay for the simultaneous detection of Cytomegalovirus, Epstein Barr virus, Herpes Simplex virus I and II, Varicella Zoster virus, enteroviruses and an internal control.
Methods: An MLPA reaction consists of three steps: first an annealing step where the 2 probes hybridise to their target region, secondly a ligation step to link the two probes, and lastly a PCR to amplify the ligated probes followed by detection by gel electrophoresis. The main advantage of using MLPA is that only one primer set is used for the final amplification reaction, in contrast to for example multiplex PCRs. This offers the opportunity to detect up to 45 targets simultaneously without affecting the reaction negatively. The MLPA reaction is preceded by a reverse transcriptase PCR to ensure the detection of both RNA and DNA viruses. In this study the MLPA assay was tested on 50 cerebrospinal fluids of patients with suspected central nervous system infection. The MLPA was performed in two centres and compared with singleplex real-time PCR analysis performed in routine diagnostic laboratories. Real-time PCR analysis were considered to be the "gold standard".
Results: MLPA results showed 100% accordance (intra-laboratory variation) and a repeatability of 92% (inter-laboratory variation). Overall the MLPA test had a inter-laboratory sensitivity of 87% (number of correct positives by MLPA/ total number of positives by real-time PCR)

and a inter-laboratory specificity of 94% (number of correct negatives by MLPA/ total number of negatives by real-time PCR). When analysed per target individually, the inter-laboratory sensitivities were between 90 and 100% except for CMV, where no positive samples were tested, and EBV, where no positive sample could be identified. The inter-laboratories specificities per target varied between 98% and 100%.

Conclusions: In conclusion, although further optimisation is needed to improve the EBV detection and CMV positive samples should be tested, this MLPA assay is a new promising tool in the field of rapid simultaneous detection of infectious agents causing central nervous system infections.

P992 Performance of the APTIMA HPV assay as compared to Hybrid Capture-II on cytologically and histologically defined specimens

J. Dockter, S. Joo, A. Schroeder, B. Eaton, D. Getman, C. Giachetti (San Diego, US)

Objectives: The APTIMA HPV Assay detects HPV E6/E7 mRNA from 14 high-risk types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, 68) in liquid Pap specimens. It utilises Gen-Probe's target capture, Transcription-Mediated Amplification, and Hybridisation Protection Assay technologies, incorporates an internal control, and can be run on both the semi-automated Direct Tube Sampling (DTS) instruments and the fully automated TIGRIS DTS System (TIGRIS). In this study, the performance of the APTIMA assay was evaluated in residual Cytyc PreservCyt liquid-based cytology samples from US and France referral populations, including samples determined to contain atypical squamous cells (ASC), and samples classified as CIN 1–3.

Methods: PreservCyt samples (n = 367) were diluted 1/4 in APTIMA specimen transport media and tested on TIGRIS. Samples were also tested using the Digene Hybrid Capture 2 (HC2) assay following its standard assay procedure.

Results: The APTIMA assay detected 259 of the 367 samples tested (70.6%) and the HC2 assay detected 260 (70.8%). The reactivity rate for the APTIMA assay in ASC samples was 69.1%. For these same samples the HC2 assay reactivity rate was 81.8%. For samples determined to be CIN-1, -2, or -3 (n = 375), APTIMA assay reactivity rates were 76.8%, 95.5%, and 96%, respectively, while HC2 assay reactivity rates were 76.8%, 93.2%, and 92%, respectively. For samples determined to be CIN 2 or -3 (n = 319), the APTIMA assay achieved 95.8% reactivity, while HC2 assay reactivity was 92.4%. Inter-assay concordance was 87.5% overall, 80% for the ASC samples, and 95% for the CIN-2 or -3 samples.

Conclusion: The APTIMA HPV assay exhibited lower reactivity than the HC2 assay in samples with ASC cytology, and higher reactivity than the HC2 assay in disease-positive (CIN-2 or -3) samples. Concordance between the APTIMA and HC2 assays was 95% in histologically disease-positive specimens.

P993 Analysis of VZV and HSV in different matrices by the use of affigene kits

N. Finnstrom, K. Bergsten, H. Strom, A. Sauerbrei, P. Wutzler (Maurens-Scopont, FR; Bromma, SE; Jena, DE)

To date there is no consensus on how to best diagnosing for varicella zoster virus (VZV) and herpes simplex virus (HSV), which sample matrix to use or which technology. Real-time PCR may offer excellent performance for this type of diagnosing. However such a method not only needs to be sensitive and specific but must be flexible and validated to handle different matrices, and fit together with a diversity of methods for sample extraction.

Objectives: The aim of this study was to analyse a wide range of matrices for VZV and HSV 1 and 2 using the affigene® VZV tracer and the affigene® HSV 1/2 tracer kits (Cepheid AB, Bromma, Sweden), respectively. The results from the commercial PCR assays were compared to in-house PCR assays.

Methods: DNA from 178 samples diagnosed for VZV and 352 samples diagnosed for HSV from 22 or 8 different matrices, respectively, were prepared using Qiagen blood mini kit (Qiagen, Hilden, Germany). Subsequently, the presence of VZV and HSV-1 and 2 was analysed using affigene® VZV tracer and affigene® HSV 1/2 tracer, respectively, on the Mx3000P instrument (Stratagene, La Jolla, USA). Fifty-two samples were also prepared using affigene® DNA extraction (Cepheid AB, Bromma, Sweden) according to the manufacturer's instructions and analysed using affigene® HSV 1/2 tracer. Prior to this study the samples had been analysed using Qiagen blood mini kit and an qualitative in-house PCR. Positive and negative agreement were calculated.

Results: Generally more positive samples were detected using affigene® assays in combination with the Qiagen blood mini kit preparation system compared to the in-house assays. In e.g. CSF six (of 40 samples) were detected positive for VZV using affigene® VZV tracer while only one using the in-house method. For HSV-1 detection the corresponding numbers in CSF were 5 compared to 3 of 40 for affigene® HSV 1/2 tracer and in-house assay, respectively. For HSV-2, 6 compared to none of 40 were detected with respective assay.

The positive agreement, for analysing VZV in all matrices was 85% and the negative agreement was 92%. For HSV-1 the corresponding figures were 97% and 89%, respectively, and for HSV-2 100% and 90%, respectively.

Conclusions: Affigene® VZV tracer and affigene® HSV 1/2 tracer are sensitive assays for detection of varicella zoster and herpes simplex viruses. A wide variety of sample matrices can be analysed using either Qiagen blood mini kit or affigene® DNA extraction as sample preparation method.

P994 Specific detection of hepatitis C virus in clinical samples using a novel simplification strategy

N. Boulter, S.P. Siah, C.J. Vockler, N.A. Coulston, K. Warton, P. Rajasekariah, J.R. Melki, D.S. Millar (Sydney, AU)

Objective: We have shown previously that DNA simplification is a novel procedure that is able to specifically detect all high-risk strains of the Human Papilloma Virus in a single reaction. We wished to determine if it was possible to use a modified simplification strategy to detect RNA encoding viruses and used Hepatitis C virus (HCV) as a model organism.

Background: HCV is a major cause of chronic hepatitis, cirrhosis and liver cancer on a global scale. One of the most sensitive methods for the detection of HCV is reverse transcription PCR (RT-PCR), which in addition to improved sensitivity compared to serological methods, can also be used to monitor disease activity in response to anti-viral drugs. We aimed to produce a simplification-based RT-PCR assay for HCV RNA that was as sensitive and specific as current viral-load monitoring assays.

Methods: Treatment of DNA with sodium bisulfite results in the conversion of cytosine residues to uracil, which are subsequently amplified as thymine. Although such methods have been applied to the detection of DNA viruses such as HPV, the treatment of RNA with sodium bisulfite results in total degradation of the RNA and thus was of no clinical utility. We have developed a novel method for the simplification of RNA using sodium bisulfite, which eliminates RNA degradation and shows similar sensitivity and specificity to conventional approaches.

Results: Baseline sensitivity tests were conducted using serial dilutions of HCV (Acrometrix cat# 96–0203) diluted in normal human serum and purified using the Qiagen QiAmp UltraSens viral kit. Positive signals were generated from as little as 15 IU/mL of virus, indicating negligible RNA degradation. In addition, a number of commercially available panels were obtained including; BBI Diagnostics Genotype Panel (PHW202), Worldwide HCV panel (WWHV301), HCV RNA genotype performance panel (PHW202) and HCV RNA linearity panel (PHW804), all of which produced results indicating that the HGS simplification strategy performed as well as conventional RT-PCR. Furthermore, sequencing of amplicons derived from different genotypes demonstrated that the method could be used for genotyping individual

HCV strains. Finally the method was assessed on a blinded panel of clinical samples the results of which shall be discussed in more detail.
Conclusion: RNA simplification is a novel approach for the reliable detection and genotyping of RNA containing pathogens such as HCV or HIV.

P995 Development of immuno-polymerase chain reaction as a highly sensitive method for viral detection

Y.J. Chan, J. Huang, A.Y-M. Chen, D.M-T. Ho (Taipei, TW)

Objectives: To develop a more sensitive and rapid method for viral antigen detection, the study combined an immune response (antigen-antibody) and a polymerase chain reaction (PCR) to form a new method, immuno-PCR (IPCR). The goal is to enhance the detecting limit of the conventional enzyme-linked immunosorbent assay (ELISA).
Methods: A monoclonal antibody, mAbH3 or mAbN, which recognises the influenza A (H3N2) or a SARS-coronavirus recombinant antigen (GST-N), was covalently linked to a cytomegalovirus DNA fragment (394 bp) respectively to form a protein-DNA complex, mAbH3-DNA or mAbN-DNA. The complex was purified and used for the reporting second antibody. To compare the detection limits of the conventional ELISA and IPCR, first antibodies against influenza A or SARS-coronavirus antigens were fixed onto micro-well plates with serial diluted standard antigens (HA titer more than 1:160 or GST-N) as the targets. Conventional secondary antibodies and the antibody-DNA conjugates were used for reporting the antigen levels.
Results: By using a quantitative real-time PCR the calculated copy numbers of the mAbH3-DNA IPCR correlated with the levels of the target antigens with the detecting limit down to 1:1000 dilutions, while the detecting limit of the conventional ELISA was 1:10 under the same experimental conditions.
A similar experiment using the SARS-coronavirus antibody-DNA conjugates revealed that the detecting limit for GST-N was 2 ng/ml, while the detecting limit of the conventional ELISA was 30 ng/ml.
Conclusions: IPCR is more sensitive than conventional ELISA for viral antigen detection. It is promising to adopt IPCR to detect small amount of viral products.

P996 Evaluation of real-time PCR assay for early detection of Cytomegalovirus infection in solid-organ transplant recipients

M. Pape, K. Mandraveli, D. Papadopoulou, E.I. Kazakos, S. Alexiou-Daniel (Thessaloniki, GR)

Objective: The aim of this study was to evaluate the advantages of Real-time PCR for early detection of CMV infection in solid-organ transplant recipients by comparison to four serology methods such as ELISA, Capture-ELISA, IFA, Western-blot.
Methods: The study included 90 solid-organ transplant recipients with clinical manifestations of recent CMV infection. Whole blood specimens and sera were collected from all patients. The whole blood specimens were processed with Real-time PCR (artus CMV LC PCR, QIAGEN) to detect CMV viral load, while the same assay was employed to detect EBV (LC EBV Quantification, Roche) and HSV/VZV (artus LC, QIAGEN) in 67 and 38 samples, respectively. All sera were tested for anti-Cytomegalovirus IgG/IgM antibodies by ELISA (AXSYM Abbott). IgM positive results were confirmed by Capture-ELISA (CE-Bouty), indirect immunofluorescene (IFA, Focus) and Western-blot (Wb-Immunogenetics) assays.
Results: CMV viral load was detected in 20 patients, while 7 of these patients had evidence of EBV co-infection(PCR+). EBV viral load was detected in 14 specimens, but no HSV or VZV DNA was detected. ELISA revealed an anti-CMV IgG positive rate of 90% in both PCR positive and negative patients. IgM antibodies were present in 15/20 (75%) CMV PCR positive patients and in 14/70 (20%) CMV PCR negative patients. The positive rates of the rest serology assays for the PCR(+) and ELISA IgM(+) patients were Capture Elisa (+) 84%, IFA (+) 73%, Western-blot (+) 88%, while the respective rates for the PCR(−) and ELISA IgM(+) patients were Capture Elisa (+) 50%, IFA (+) 35%, Western-blot (+) 43%. High viral load (>103 copies/ml) was detected in 10/15 patients with ELISA IgM positive results. Low viral load (<103 copies/ml) was detected in 5/20 patients with ELISA IgM negative results
Conclusion: The referring doctors are requested to provide more clinical informations. Double samples should be tested by all serology assays in order to access a safe diagnosis and eliminate the possibility of false negative and positive results. Evaluation of viral load by Real-time PCR seems to be more sensitive and specific for the early detection of CMV infection than the serology assays.

HIV

P997 Relationship between gastric secretion, bacterial and fungal colonisation and histological changes in gastric mucosa in HIV-infected patients

P. Skwara, I. Sobczyk-Krupiarz, A. Ciesla, J. Loster, T. Mach (Cracow, PL)

Objectives: Abnormal secretion of acid gastric juice in the course of HIV infection may result in bacterial and fungal overgrowth in stomach. The aim of the study was to estimate gastric secretion in HIV-infected patients (pts) in relation to severity of immunodeficiency and route of HIV transmission as well as influence of changes in gastric secretion on bacterial and fungal colonisation of stomach and gastric mucosa histology.
Methods: 71 HIV-infected pts were studied, 35 with CD4 lymphocyte count <200/uL (group 1) and 36 with CD4 >200/uL (group 2). Biopsy samples were taken during endoscopy from corpus and antrum of stomach for histological analysis and gastric juice samples were taken for quantitative bacteriological and mycological analysis. Gastric secretion was evaluated in 37 pts belonging to group 1 (19pts) and group 2 (18pts) on the basis of BAO, MAO and PAO analysis. In this group, route if transmission in 21 pts was intravenous (drug addicts), whereas sexual in the rest of patients.
Results: However no statistically significant difference in BAO between the two groups was noted, statistically significant decrease in gastric secretion /p<0.05/ was found in group 1 in comparison to group 2 (MAO 11.8vs18.3; PAO 14.8vs22.7 mmol HCl/h). Such relationship appeared to be much more evident in pts infected via sexual route (MAO 7.4vs20; PAO 9.3vs25). Gastric juice culture in pts with MAO<10 mmol HCl/h in comparison to the rest of pts, revealed more frequent significant growth of both fungi (58%vs32%) and bacteria (33%vs8%). Pts with fungal colonisation $>10^4$ CFU/mL had lower BAO (1.8vs3.3), MAO (11.2vs17.5) and PAO (14.5vs21.5) in comparison to the rest of pts. Similarly, pts with bacterial colonisation $>10^4$CFU/mL had lower BAO (1.3vs3.0), MAO (8.8vs16.1) and PAO (11.2vs20.1). No statistically significant correlation was found between bacterial colonisation and histological changes in gastric mucosa except for higher prevalence of chronic active gastritis in corpus of stomach /p<0.05/. Fungal colonisation correlated with higher prevalence of chronic non-active gastritis in corpus of stomach /p<0.01/.
Conclusions: Significant decrease in gastric secretion was found in severely immunocompromised HIV-infected pts, provided they were not intravenously infected drug addicts, followed by more frequent bacterial colonisation which correlated with chronic active gastritis and fungal colonisation which correlated with chronic non-active gastritis in corpus of stomach.

P998 Differences in health resources use and associated cost between HIV immigrants and Spaniards

M. Velasco, V. Castilla, L. Moreno, R. Hervas, J. Losa (Madrid, ES)

Objective: The specific impact of immigration on health services utilisation and related cost have been hardly analysed. To compare resource utilisation patterns among HIV-infected immigrants and Spaniards and to estimate the direct healthcare costs of HIV/AIDS care in both groups of patients we designed this study.

Methods: All adult patients with HIV infection attended during the years 2003 – 2005 in a secondary teaching hospital. Immigrant was considered a patient non-born in Spain. We evaluated episodes of health resource consume: hospitalisation, any kind of out-patient visit, emergency room visit without hospitalisation, any kind of hospital-day care, out-patient surgery, and HAART dispensation. For the cost calculation, we used a unitary cost for DRG per admission, officially assigned standard costs for cost of individual out-patient and ER visits and real cost of Pharmacy. We compared all variables between immigrant and Spaniards.
Results: During the period of study 372 patients were attended, 12% immigrants. They generated 9662 episodes of health resources consume, 11.4% from immigrants. Number of hospital admissions per patient was higher in immigrants 1.3 (4.4) than Spaniards 0.9 (2.7), p = 0.03. There were no differences in case-mix 2.2 (1.4) and 2.1 (1) and unitary cost per admission (1511 and 1539€), number 9.2 (8.8) vs 9.8 (11.8) p = 0.85 and cost (46.9 (18.6) vs 45.3 (18.9) € p = 0.1) of out-patients visits per patient and ER visits (1.6 (1.7) vs 2.7 (4) p = 0.26 and ER cost per patient (94.1 vs 157.8 € p = 0.33) between immigrants and Spaniards respectively. The cost of HAART per patient was slightly higher in Spaniards 7351.8€ than immigrants 7153.9€, p = 0.01. The proportional distribution of health resources use was different: hospitalisation was more used in immigrants and ER visits in Spaniards. The global distribution of cost was similar between both groups, and 75% were attributed to HAART. Total cost per patient did not differ between both groups.
Conclusions: There were no major differences in the use of health resource and associated cost between immigrants and Spaniards, except for a higher use of hospitalisation in immigrant population. HAART dispensation is the main health resource used and principal reason for expense in both groups.

P999 HIV-associated pulmonary hypertension: to screen or not to screen?

S. Cicalini, P. Chinello, F. Lisena, N. Petrosillo and the Latium Registry for HIV-associated Pulmonary Hypertension

Objectives: Pulmonary hypertension (PH) is a well-known cardiovascular disease with a poor prognosis that occurs in HIV-infected patients with a frequency of 0.5% compared with the 0.02% in the general population. On April 2004 in the Latium Italian Region, with an estimate of 5000 HIV-infected subjects, a Registry of PH in HIV-infected subjects was instituted. HIV-infected patients diagnosed as having PH after undergoing a diagnostic algorithm for clinical suspicion of PH, were enrolled in the Registry. The availability of new therapeutic options for PH allowing a better prognosis led us to submit to an echocardiographic screening HIV-infected asymptomatic subjects followed-up at our outpatients clinic. Aim of this study was to estimate the frequency of PH in HIV infected patients without cardiopulmonary symptoms.
Methods: 510 consecutive HIV-infected outpatients with no symptoms or signs of cardiopulmonary disease underwent echocardiography to evaluate pulmonary systolic arterial pressure. Clinical characteristics of HIV-PH asymptomatic patients were then compared with those of symptomatic patients with HIV-PH enrolled in the Registry.
Results: Between April 2004 and November 2007, 23 out of 510 patients (4.5%) were found to have an elevated PSAP. Four out 23 (4/510, 0.8%) were classified as having HIV-PH according to Venice classification. Secondary causes of PH were identified in 16 patients. Three patients are still undergoing diagnostic procedure for classification of PH. Data on asymptomatic and symptomatic HIV-PH patients are shown in table 1.
Conclusions: HIV-PH could be more frequent than expected, and probably latent for many years. Since PH could complicate the course of HIV infection regardless the degree of immunosuppression, and represents a significant cause of morbidity and mortality, a systematic cardiopulmonary evaluation and follow up should be incorporated in the clinical management of HIV infected patients. An early diagnosis and a proper follow-up could ameliorate the prognosis of PH.

P1000 Relationships between urinary IL-18, MMP-9 and BMP-7 concentration and renal lesion in HIV-1 infected patients

M.M. Dabrowska, A. Wiercinska-Drapalo, E. Siwak, R. Kranc, R. Flisiak (Bialystok, PL)

Objectives: HIV infection of glomerular endothelial and mesangial cells can cause progressive renal lesion. IL-18 and MMP-9 which are overexpressed during an HIV-1 infection can stimulate proinflammatory response in the kidney, which can be counterbalanced by increased production of BMP-7.
Methods: A cross-sectional study was performed in 76 HIV (+) patients (57 male, 19 female, aged from 20 to 59 years, 58 on HAART) and 17 HIV (–) volunteers. Plasma HIV-1 RNA was evaluated using the Amplicor system. Urinary IL-18, MMP-9 and BMP-7 concentration was measured by ELISA (Ray Bio and R&D Systems respectively). Creatine clearance was calculated by using of Cockroft-Gault formula. In statistical analyses U Mann-Whitney and Spearman correlation tests were used.
Results: We observed the increase in urinary MMP-9 and the decrease in urinary IL-18 in HIV (+) patients in comparison to control group (6.09±1.39 v. 4.5±0.94 ng/ml, $p<0.05$ and 15.28±2.54 v. 42.66±11.02 pg/ml, $p<0.05$). There were no significant differences in urinary BMP-7 regarding to HIV (–) group (2.61±0.54 v. 3.16±0.68 pg/ml, p = 0.09). No significant correlation was found beetwen CDC classification and urinary IL-18, MMP-9 and BMP-7 concentration. The mean urinary MMP-9 concentration observed in patients undergoing HAART was significantly lower than in patients without ARV treatment (4.97±0.98 v. 10.18±4.76 ng/ml, $p<0.05$). HIV-1 RNA was positively correlated with urinary MMP-9 concentration in HIV (+) (r=0.29, $p<0.05$). Moreover urinary MMP-9 concentration was positively correlated with urinary BMP-7 concentration (r=0.34, p = 0.005) and negatively correlated with creatine clearance (r=-0.32, $p<0.05$) in studied population.
Conclusion: Increased urinary MMP-9 concentration is associated with plasma HIV viral load and could be a new biomarker of subclinical renal lesion. MMP-9 augment together with BMP-7 increase may be explained by compensatory protection mechanism against renal damage.

P1001 Heart rate variability in AIDS-patients co-infected with *T. cruzi*

D. Correia, R.J. Molina, L.A. Resende, S.F.N. Oliveira, F.F. Neves, V. Silva (Uberaba, BR)

Background: Chagas disease caused by the protozoan *Trypanosoma cruzi* and transmitted by the triatomid bugs is highly prevalent in almost all Latin and Central American countries affecting between 11–13 million peolple. HIV infection is also high widespread in such countries. Cardiac autonomic impairment has been well characterised

in chronic chagasic cardiomyophaty as well as in HIV/AIDS related heart involvement.
Objectives: Evaluate the cardiac autonomic function by using the computarised analysis of heart rate variability in patients with the co-infection HIV/Chagas disease.
Methods: With the ethical approval, we studied 57 patients, gender- and age-matched, 19 (*T. cruzi*-HIV group), 19 (HIV group) and 19 (control group). A continuous ECG recording in DII lead was performed in supine rest, cold face and passive tilt tests and R-R intervals were acquired. The overall variability of R-R series was assessed in the time and frequency domains using autoregressive power spectral analyses.
Results: The groups were similar regarding to gender and age. The electrocardiographic's analysis of mean values of R-R intervals did not differ in the three studied groups (p= 0.814). In baseline, the HIV group showed a statistically significant increase of the low frequency area, compared with the co-infected group (p = 0.01), a decrease of normalised low frequency area, compared with co-infection group (p = 0.03), an increase of the high frequency area compared with co-infected (p = 0.03). The variance was significantly higher in the co-infected group compaired with the HIV-group (p = 0.03).
Conclusion: In baseline conditions, a shift of cardiac sympathovagal balance, suggestive of an impairment of sympathetic modulation, was detected in patients with the *T. cruzi*/HIV co-infection.

Table 1: R–R intervals, Variance and Spectral Components in Control, HIV and *T. cruzi*/HIV groups in baseline

Indices	Control Group (n = 19)	HIV (n = 19)	*T. cruzi*/HIV (n = 19)	P value
Mean RRi (ms)	856.72 (734–952.5)	854.05 (777.5–934.5)	824.52 (726.5–923.5)	NS
Variance (ms^2)	439.77 (489.3–889.45)	3346.36 (3622–717)*	4591.5 (249.5–1245.5)[#]	0.03
LF (Hz)	124.57 (0.09–0.11)	0.09 (0.08–0.11)	0.08 (0.06–0.1)	NS
LF power (ms^2)	152.13 (93.06–270.5)	826.26 (189.7–1104)*	980.7 (11.47–269.05)[#]	0.01

LF/HF ratio	2.37 (1.14–3.24)	1.72 (0.73–2.37)	2.95 (0.24–3.45)	NS

A one-way ANOVA was used for statistical comparisons. RRi: R–R intervals; LF: Low frequency area; HF: High frequency area; LF n.u.: Low frequency area in normalised units; HF n.u.: High frequency area in normalised units.
*$p < 0.05$ in comparison to Control Group; [#]$p < 0.05$ in comparison to HIV group.

P1002 Bloodstream infections among human HIV-infected adult patients: epidemiology and risk factors for mortality

M. Ortega, M. Almela, A. Soriano, F. Marco, J. Martínez, J. Mallolas, J. Gatell, A. Muñoz, J. Mensa (Barcelona, ES)

Background: Bloodstream infections are a frequent complication found in HIV-infected patients and are usually associated with a poor prognosis.
Objectives: This study was undertaken to describe the epidemiology and sensitivity pattern of pathogens causing community-acquired (CA) and nosocomial (N) bloodstream infection (BSI) in adult HIV-infected patients along the fifteen last years, to establish risk factors for mortality and hence to give guidance in the choice of empirical antimicrobials.
Methods: The type of study was a retrospective analysis of BSI episodes prospectively collected through a blood culture surveillance program from January 1991 to December 2006. We used non-conditional logistic regression methods with death as dependent variable.
Results: 1,077 (6%) episodes of BSI occurred in HIV-infected patients out of 16,946 total episodes in the period of study. CA and N BSI were 634 (59%) and 443 (41%), respectively. *S. pneumoniae* and *S. aureus* were the most frequent pathogens (n = 279, 44%) in CA BSI. Coagulase negative staphylococci and *S. aureus* were the most frequent microorganisms isolated in N cases (n = 369, 38%). Cotrimoxazole resistance was common in CA and N BSI caused by Gram-negative bacilli (50% and 61%, respectively). However, resistance rates to ceftriaxone were low (3%). Crude mortality accounted for 140 cases (13%). The independent risk factors associated with mortality were: liver cirrhosis (OR: 2.90, 95% CI: 1.55–5.41, p= 0.001), corticosteroids treatment (OR: 3.51, 95% CI: 1.87–6.56, p< 0.001), neutropenia (OR: 2.21, 95% CI: 1.15–4.23, p= 0.02), inappropriate empirical therapy (OR: 2.44, 95% CI: 1.29–4.65, p= 0.006) and isolate of *C. albicans* (OR: 7.58, 95% CI: 1.61–35.65, p= 0.010).
Conclusions: BSI in adult HIV-infected patients was often caused by Gram-positive pathogens in both CA and N settings. An inappropriate empirical therapy and the presence of other immunosuppressive factors were independent risk factors for mortality. Ceftriaxone could be used as the initial empiric therapy for HIV-infected patients with suspected CA BSI.

P1003 Clinical performance of FXG:RESP (Asp +) assay for *Pneumocystis jirovecii* on respiratory specimens

P. Hauser, K. Lagrou, X. Cui, C. Lass-Florl, D.S. Perlin, S. Park, J. Maertens, M. Hughes, P. Bowyer, D.W. Denning, J. Bille (Lausanne, CH; Leuven, BE; Manchester, UK; Innsbruck, AT; Newark, US)

Objectives: *Pneumocystis* pneumonia continues to be a common infection in HIV patients and also occurs in other immunocompromised patients. Early diagnosis is known to improve outcome, and specifically, exclusion of the diagnosis, reduces the need for toxic empirical high dose cotrimoxazole therapy. Real-Time PCR offers the prospect of faster and highly sensitive detection of *P. jirovecii*. FXG:RESP (Asp +) [Myconostica, UK] is a test kit that detects both *P. jirovecii* and *Aspergillus* spp., utilising molecular beacons. In this report we focus on the clinical performance for *P. jirovecii*.
Methods: The FXG:RESP (Asp +) real-time PCR kit utilises the large subunit mtRNA gene as a target to detect *P. jirovecii* and the assay is highly sensitive, being able to detect 6 target copies. The assay appears to be specific for *Pneumocystis* spp., with the possible exception of *Fusarium solani*. It was tested blindly on 196 BAL samples, collected from 4 European hospitals. All results were compared to microscopy, usually Calcofluor or Gomori methanamine silver stains, performed shortly after the sample was collected, and in non-AIDS patients whether patient was treated for PCP. Most HIV/AIDS samples had been previously extracted and stored frozen as DNA; the remainder were extracted with the MycXtra™ fungal DNA extraction kit, having been stored frozen unprocessed.
Results: The kit contains an internal amplification control to detect potential inhibition of the PCR reaction and 6 (3%) of the clinical samples showed evidence of inhibition. These results were excluded from analysis, although 5 were positive by both microscopy and the FXG:RESP (Asp +) assay, and would be reported clinically. 42 samples were from HIV/AIDS patients and 148 from other patients, mostly with leukaemia. With respect to *Pneumocystis* detection, the FXG:RESP (Asp +) assay had good performance with a sensitivity of 97.4%, specificity of 92.9%, positive and negative predictive values of 90.4% and 98.1%. 8 samples had negative microscopy but very high FXG assay signals, suggesting that the microscopy was falsely negative, as reported in prior literature. These were reported as false positives
Conclusions: The clinical performance of the FXG:RESP (Asp +) assay for the diagnosis of *Pneumocystis* pneumonia is superb. Overall the speed of detection and sensitivity of the FXG:RESP (Asp +) assay should bring substantial clinical benefits. Prospective and supportive clinical trials are ongoing.

P1004 Effectiveness of vaccination against HBV infection in HIV-infected persons

A. Kalinowska-Nowak, T. Mach, M. Bociaga-Jasik, A. Garlicki, P. Skwara (Cracow, PL)

Objectives: The aim of the study was assessment of the efficacy of the standard vaccination against HBV among HIV infected patients and vaccination with additional doses in patients who did not develop the protective level of antibody after the initial vaccination. Influence of the stage of HIV infection was analysed.

Methods: 54 HIV infected individuals, 20 women (37%) and 34 men (63%), mean age 32 years were analysed. 32 patients (59.6%) were treated with antiretroviral drugs. Stage of HIV infection was assessed on the basis of data derived from medical records and immunological status at the moment of introduction of vaccination (CD4 cells count, viral load). Efficacy of vaccination was compared with control group (56 healthy volunteers). In both groups hepatitis B virus infection was excluded by serologic tests. HBvaxPro vaccine produced by Merck Sharp & Dohme Company, dose registered for adults was injected at month 0–1-6. Patients with anti-HBs < 10 IU/l have received booster doses of vaccine month intervals, no more then three.

Results: Protective level of antibodies was found in 52 (92.9%) persons from control group and 32 (63%) HIV infected individuals. Anti-HBs > 100 IU/l was twice more common in control group (80%) than in investigated group (46.3%) (p<0.001). Protective level of anti-HBs had 14.3% patients with CD4 below 200 cells/μl, none of them had anti-HBs > 100 IU/l. Patients with higher CD4 cell count had better response for vaccination (p = 0.015). Differences between patients with high and low viral load were not statistically significant (p = 0.015) but patients with viral load below 10 000 copies/ml had slightly better response then those with higher viral load. Efficacy of vaccination was also associated with the level of distraction of immunological system before introduction of HAART (patients with CD4 < 200 cells/μl or HIV-RNA > 50 000 copies/ml had worst immunological response for vaccination). After the fist additional dose of vaccine anti-HBs > 10 IU/l had 79.7% patients, 87.1% after the second dose and 90.7% after the third dose. Anti-HBs > 100 IU/l had subsequently 57.4%, 66.7%, 79.6% patients.

Conclusions: Effectiveness of the routine vaccination schedule was lower among HIV individuals in comparison with healthy volunteers. Influence of the progression of HIV infection on the response for vaccination was detected. Additional vaccine's doses have improved efficacy of immunisation which was comparable with general population.

P1005 Factors associated with presence of isolated anti-HBc antibody in HIV-infected persons in Taiwan

C-C. Hung, W-C. Ko, J-J. Tsai, C-E. Liu, W-W. Wong, S-C. Su, M-W. Ho, S-H. Cheng, C-H. Yang, Y-H. Lin, W-J. Miao (Taipei, Tainan, Kaohsiung, Chung-Hwa, Hsin-Chu, Taichung, Tao-Yuan, Hwa-Lien, TW)

Objectives: To determine factors associated with presence of isolated anti-HBc antibody (positive anti-HBc antibody with negative HBsAg and anti-HBs antibody) in HIV-infected persons in Taiwan where the prevalence of chronic hepatitis B virus (HBV) infection is 15–20% in the general population aged 25 years or greater and vertical transmission is the major transmission route for HBV.

Methods: Clinical characteristics of 403 HIV-infected persons aged 15 years or greater who had an isolated anti-HBc antibody pattern were compared with those of 943 HIV-infected persons who developed protective HBV immunity after HBV exposure (negative HBsAg; positive anti-HBs and anti-HBc antibody). HBV DNA was measured in 68 persons with isolated anti-HBc antibody who had available serum specimens. Among these 68 persons in whom 45 persons had available anti-HBs titers, the relationship between HBV DNA load and anti-HBs titer levels were analysed.

Results: In univariate analysis, factors associated with presence of isolated anti-HBc antibody included older age (41 vs. 37 years, p<0.001), sexual transmission route (66.6 vs. 60.1%, p = 0.033), lower median CD4 counts (203 vs. 295 cells/μgL, p<0.001), and high plasma HIV RNA load (4.65 vs. 4.44 log10 copies/mL, p = 0.008); HCV seropositivity and intravenous drug use were not independent associated factors. In multivariate analysis, independent associated factors were age (odds ratio, 1.022, 95% CI 1.011–1.034) and a CD4 count less than 100 cells/μgL (odds ratio, 1.605, 95% CI 1.236–2.083). Among the 68 persons with isolated anti-HBc antibody and HBV DNA measurement, 14.7% had detectable HBV DNA. Of the 45 persons with isolated anti-HBc antibody who had determinations of both anti-HBs antibody titers and HBV DNA load, 38 (84.4%) had titers between 1 and 10 mIU/mL. Only 13.2% of these 38 persons had detectable HBV DNA while 28.6% of the 7 persons with anti-HBs titer less than 1 mIU/mL had detectable HBV DNA load (p = 0.296).

Conclusion: We concluded that, different from what have been reported by investigators in the Western countries that chronic HCV infection is associated with isolated anti-HBc antibody pattern, age and CD4 counts lower than 100 cells/£gL were associated with presence of isolated anti-HBc antibody in HIV-infected persons in Taiwan, and compromised immunity with subsequently waning of anti-HBs titers might play a role.

P1006 Characteristics of patients with a short delay between the first HIV-positive screening test and the diagnosis of AIDS at Lyon University Hospitals, France from 1985 to 2007

D. Baratin, D. Peyramond, C. Trepo, J.L. Touraine, C. Chidiac, P. Vanhems (Lyon, FR)

Objectives: A diagnosis of AIDS shortly after a detection of HIV antibodies suggests a long lasting course of disease without treatment. To explore a late access to care, we studied the factors associated with a short delay (Sh.D) between the first HIV positive screening test and AIDS.

Methods: Prospective anonymous cohort study of 2253 patients with AIDS followed since 1985 to 2007 with confirmed dates of the first HIV positive screening and AIDS (European AIDS definition) at Lyon University Hospitals. Population was stratified into 2 groups according to a delay > or ⩽3 months (M) between the first detection of HIV-1 antibodies and AIDS. Two periods before and after introducing HAART (1996) were analysed. Multiple logistic regression was used to identify the factors associated with a delay ⩽3 months (Sh. D) based on their odd-ratio (OR) and 95% confidence interval (95% CI).

Results: A total of 736 individuals (32.7%) were in the Sh.D. group. The multivariate analysis identified factors associated with a Sh.D: age (per 1 year increase) OR 0.95, [95% CI 0.94–0.97], male gender (OR 2.04, [95% CI 1.32–3.20]), heterosexual intercourse (OR 2.03 [CI 95%: 1.42–2.91]), injecting drug use (OR 0.30 [95% CI 0.15–0.58]) and other exposure of HIV infection (OR 2.31 [95% CI 1.49–3.56]) compared to homosexual intercourse, CD4 $<100/mm^3$ at AIDS (OR 1.69 [95% CI 1.24–2.29]), *Pneumocystis jirovecii* pneumonia as initial AIDS event (OR 1.84 [CI 95% 1.15–2.92]), oesophageal candidiasis (OR 0.37 [95% CI 0.21–0.64], lymphoma (OR 0.32 [95% CI 0.16–0.64] compared to Kaposi's sarcoma diagnosis, AIDS diagnosis after 1996 (OR 3.96 [95% CI 2.88.-5.44]) and two simultaneous opportunistic infections at AIDS (OR 1.55; 95% CI 1.08–2.21) compared to one.

Conclusion: Gender, route of infection, age at first positive screening, recent years of AIDS diagnosis and an advanced immunosuppression were independently associated with a Sh.D between HIV-1 infection detection and AIDS. These results provide opportunities to plane interventions to populations who are most likely to access lately to care after HIV infection. The reasons of a late access to care need to be explored urgently for individual and public health benefits

P1007 Seasonal variation of *Pneumocystis jirovecii* infection: analysis of underlying climatic factors

A. Sing, S. Schmoldt, M. Wildner (Oberschleissheim, Munich, DE)

Objectives: *Pneumocystis jirovecii* pneumonia (PCP) represents a serious opportunistic infection in immunocompromised patients. However,

the modes of transmission are still not completely elucidated. Seasonal changes of PCP incidence might be associated with climate changes. Therefore, we explored the relationship between PCP incidence and climatic factors.

Methods: Between April 1992 and December 2006, 576 microscopically confirmed cases of PCP were diagnosed at the Max von Pettenkofer-Institute serving the major hospitals in Munich, Germany, for laboratory diagnosis of *P. jirovecii*. The monthly incidence of PCP – both for the pre- and post-HAART area, respectively – were correlated with the three most important monthly weather data for Munich obtained from the German Weather Service., i.e. mean temperature (°C), height of precipitation as a measurement for rainfall activity (mm) and wind strength (Bft). Statistical methods used were bivariate graphical exploration and multiple linear regression modelling of the influence of weather parameters on the monthly incidence rates as dependent variable with adjustment for mean annual incidence and logarithmic transformation to achieve normal distribution.

Results: While there was a clear seasonal pattern in PCP incidence with two peaks in May and August, no significant correlation was found between PCP incidence and rainfall activity or wind strength. In contrast, PCP incidence was positively correlated with the mean monthly temperature. This correlation seems to be more pronounced in the post-HAART area than in the pre-HAART period.

Conclusion: To our knowledge, this is the first study using multiple linear regression statistics on monthly climatic data. In contrast to previous and more descriptive studies from Spain and the UK showing season-related PCP incidence patterns with maxima in the winter months – as it is known from other infectious respiratory diseases, we found an opposite incidence pattern with PCP incidence maxima in late spring and summer. Moreover, PCP incidence was positively correlated with the mean temperature. Possible explanations for this seasonal variety of PCP incidence will be discussed.

P1008 Anti-R7V antibodies prevalence in HIV-infected patients followed in the ambulatory care centre of a university hospital, Cotonou, Benin

E. Lafia, M. Houeze, M. Zannou, A. Bigot, F. Guedou, S. Anagonou, I. Zohoun (Cotonou, BJ)

Background and Objectives: A cellular epitope (R7V) is acquired by HIV when the virus is released by budding. All known variants present this epitope at their external membrane. Induced anti-R7V antibodies were described in vitro to neutralise cell infection. Research also indicated an association between the slow or non progressor status of HIV infected patients and presence of anti-R7V Ab.

Objectives were to determine the prevalence of anti-R7V Ab in HIV patients followed in the Ambulatory Care Centre at the University Hospital of Cotonou, Benin, and to assess the relationship of the Ab with the clinical status of patients.

Methods: A cross-sectional study was carried out from May to November 2007. 131 consenting patients were enrolled (average age was 36 and sex ratio=0.5). Blood specimens were drawn at the inclusion visit; serum sample was collected, coded and stored at −20°C until anonymous testing. Samples were tested for anti-R7V by ELISA (Ivagen, Bernis, France). The statistical Pearson chi2 test was used to compare the presence of anti-R7V Ab and the variables, clinical status of the patients and treatment.

Results: For 114 patients among the 131, date of HIV diagnosis ranged from February 1999 to August 2007. Mode of contamination was unknown for all patients.

Anti-R7V Ab were found in 90.4% of patients HIV-diagnosed in 2006, in comparison of whose diagnosed in 2004 (43.4%), $p<0.01$. The prevalence of Ab was also highly significant ($p<0.01$) in the group of 60 asymptomatic patients (83.3%) versus the group of 71 symptomatic patients (59.1%). Less anti-R7V positive results were observed for patients under ARV treatment (53.2%) than for naive patients (85.5%), $p<0.001$. No difference was shown between immunocompromised patients (CD4 $\leqslant$200 cells/mm^3) and patients with no decline of CD4 ($\geqslant$500 cells/mm^3).

Conclusion: Prevalence study of the anti-R7V Ab in 131 HIV-infected patients showed: i) ARV treatment decreased the level of the Ab, as previously described; ii) it seems that there is no relationship with the immunocompromised status and decrease in the presence of Ab; iii) anti-R7V Ab are highly more frequent in HIV patients always asymptomatic, for whom the detection of this humoral marker could be recommended. A follow-up of the patients who tested positive for anti-R7V Ab will enable to determine whether the presence of Ab is predictive of a slower progression, or non progression toward AIDS.

P1009 Molecular epidemiology of HIV-1 in newly diagnosed patients in southern Spain

M.J. McConnell, F. Docobo-Perez, R. Mata, F. Fernandez-Cuenca, P. Viciana, L.F. Lopez-Cortes, M. Trastoy, J. Pachon, P. Perez-Romero (Seville, ES)

Objective: To characterise the subtype diversity and determine the prevalence of resistance mutations in the reverse transcriptase (RT) and protease (PR) regions of pol in treatment-naive individuals at a tertiary medical centre in western Andalucia from 2004 to 2006.

Methods: We included 72 HIV-infected, treatment-naive patients receiving care in our Hospital. Patients were categorised as either recently infected or chronically infected. Patient age, sex, risk factor, coinfection status (hepatitis B and C), viral load, and CD4+ T cell counts were determined at the time of diagnosis. Plasma HIV RNA was quantified using the Amplicor HIV-1 Monitor Test 1.5. Viral sequences were amplified and the data were used to determine the subtype diversity, prevalence of resistance mutations in the RT and PR genes and for phylogenetic analysis.

Results: The subtype B virus was present in 88.9% of the individuals, 9.7% were infected with the circulating recombinant form CRF-02AG, and 1.4% with the subtype recombinant B/G. Of 17 newly infected patients 88.2% were infected with sybtype B, 5.9% were infected with CRF02-AG, and 5.9% with B/G. Of 55 chronically infected patients 89.1% were infected with subtype B and 10.9% were infected with CRF-02AG. Interestingly, 6 of the 20 individuals (30%) identifying heterosexual contact as their primary risk factor were infected with CRF02-AG, whereas only 1 of 43 individuals (2.3%) identifying homosexual contact as their primary risk factor were infected with CRF02-AG ($p<0.01$ chi-squared). One resistance-associated mutations (RAM) in either the RT or PR genes was present in 86.1% and 83.3% had RAM to one class of antiretroviral drug, whereas 2.9% contained RAM to two classes of antiretroviral drugs. No isolates had mutations associated with resistance to all three drug classes. No primary resistance mutations within the PR gene were observed. However, 86.1% contained at least one secondary mutation within the PR gene associated with PI resistance. M36I (41.7%) and L63P (48.6%), were the most common. Mutations in the RT region were less prevalent than in the PR region. Only two isolates had mutations in RT associated with resistance to NRTIs or NNRTIs. K103N mutation was present in 2.8%, while Y188C was present in 1.4%.

Conclusion: These results elucidate the subtype diversity present in this region and suggest that the transmission of highly resistant virus variants is not occurring at a high frequency in this population.

P1010 Prevalence of CCR5, CCR2 and SDF1 genotypes in general population and HIV seropositive individuals in Georgia

M. Karchava, N. Gochitashvili, N. Dvali, N. Badridze, T. Tsertsvadze (Tbilisi, GE)

Objectives: Host genetic factors might be one of the factors determining the rate and severity of HIV epidemic in particular country, and also is an important host factor for pathogenesis and natural history of HIV disease. Unlike CCR5 delta32 mutation, mutation CCR2–64I and SDF1–3A do not provide protection against HIV infection, but still play a role in the

HIV disease progression. The prevalence of HIV in Georgia remains very low (0.01% in general population, about 1% in IDUs). Taking into consideration high prevalence of HCV and HBV infections in general population (6% and 4% respectively) and even higher in high risk groups (in IDUs 68 and 59% respectively) in our country low prevalence of HIV is unexpected. Moreover, there is high rate of IDU and STDs in Georgia; and neighboring countries where high migration of Georgian population takes place already have wide scale HIV epidemic. The objectives of this study was to study the host genetic factors in the general population and HIV infected individuals in order to study the correlations between CCR5delta 32, CCR-64I and SDF1–3A genotypes and resistance to HIV infection and/or disease progression in our country.

Material and Methods: A cross-sectional study design was utilised to examine CCR5, CCR2 and SDF1 genetic variants. 139 persons representing a non pregnant general adult population and 120 HIV infected individuals were enrolled in the study. Mutations were detected by the polymerase chain reaction/restriction fragment length polymorphism method.

Results: Of 139 individuals from general population 2.8% were caring mutations in both CCR5 genes. However, overall allele frequency (6.37) was similar to the frequency among European population. No homozygous mutation was found among HIV infected group and the allele frequency was equal to 2.5. Allele frequency of CCR2 and SDF1 allele was 14.9 and 10.75 and 36.7 and 32 among two groups respectively.

Conclusions: The frequency of CCR2 and CCR5 mutations is comparable to the frequency among European population; however, the rate of homozygous mutated CCR5 delta gene is among the highest. Moreover, to our knowledge, the frequency of SDF1–3A allele frequency in Georgians is among the highest ever reported (the highest rate reported to date is 29.75 among Cretan Greeks). According to the results of our study the frequency of those gene mutations partially might be a reason for lower HIV prevalence in the county.

P1011 Seroprevalence of HIV in Russia (1987–2006)

A. Khryanin, V. Reshetnikov (Novosibirsk, RU)

Objective: Currently the spread of HIV infection is acquiring an epidemic pattern in Russia. Thus, HIV incidence rates increased 24-fold in 2001, and the cumulative number of HIV cases reported in the country increased ten-fold compared to 1997–1998.The aim of the present study was to analyse the epidemiology of HIV infection in Western (WS) and Eastern (ES) Siberia over the period from 1987 through 2006.

Methods: Siberia consists of 14 administrative regions with total population of 32 115 697 citizens, which is about one fourth of total Russian population. The data from district STD clinics were obtained and registered in the departments of social statistics of the regional committees of statistics.

Results: HIV incidence rate in Siberia accounts for 17.0% of all HIV infected persons in Russian Federation. Additionally, the HIV incidence rate is higher than average in Russia by 13.1 percent. Trends in the incidence of HIV infection are shown in the Table (number of reported cases in Russia).

In 2002, HIV incidence rates in Irkutsk and Novosibirsk were 102.1 and 8.9 (per 100 000 inhabitants), respectively. More than 50% of all HIV cases were reported from intravenous drug users aged 19–29 years in 2004 (in comparison 80% in 2000). Males comprise 70% of newly diagnosed HIV cases. Sexual transmission was reported in 4.7% in 1999 and 54.3% in 2004. The sexual/intravenous routes ratio was 1/1.7 in 2004 (in comparison 1/21 in 1999).

	1987–1997	1998	1999	2000	2001	2002	2003	2004	2005	2006
Russia	7.02	10.95	26.41	79.88	173.00	226.00	264.99	303.27	331.55	385.30
Siberia	226	493	5.46	12.88	24.39	31.29	35.69	39.97	44.41	49.53
Novosibirsk (WS)	16	29	48	167	361	600	768	918	1.08	1.45
Irkutsk (ES)	22	47	3.29	7.99	11.56	14.06	15.65	17.38	19.43	21.50

Conclusion: At present HIV epidemic unevenly spreads in the Siberian region. There reservoirs of infection are already formed in some administrative territories such as Irkutsk (ES). As for Novosibirsk (WS), the process of formation is under way. Local intervention programmes are urgently needed to prevent the forthcoming HIV epidemic in Siberia.

P1012 Trend of prevalence of human immunodefiency virus type 1(HIV-1) non-B aubtypes in Galicia, northwestern Spain

J. Rodriguez-Calviño, S. Cortizo-Vidal, L. Rodriguez-Otero, D. Gutierrez, P. Romero-Jung, A. Prieto, E. Varela, A. Aguilera-Guirao, B. Regueiro (Santiago de Compostela, ES)

Objectives: HIV-1 non-B subtypes plays an important role in the HIV epidemic and its prevalence has increased throughout the years. Understanding the cause of this increase is important for public health strategies. The aim of this study was to observe the trend of prevalence of HIV-1 non B genotypes in Galicia (North West of Spain) between 2003 and 2007.

Methods: In a prospective study in Santiago de Compostela, from a total of 322 newly diagnosticated HIV patients, we defined subtypes by partial sequencing of the polimerase gene by means of automated sequencing (CEQ 2000 system, Beckman Coulter Inc) and phylogenetic analysis using the geno2pheno program (Max Planck Institut Informatic, http://www.geno2pheno.org).

Results: The subtype B was the most frequently isolated. The non-B subtypes proportion found between our patients were the following: non recombinant subtypes A, C, D, F and G (45.83%) and recombinant subtypes AE, AG, BF and BG (54.17%). Subtypes AG and D were the most prevalent and there were no diferences in relatives frequences of recombinant and non recombinant subtypes over the years. In newly diagnosticated HIV patients, the prevalence of non-B subtype viruses was: 3.17% in 2003, 2.59% in 2004, 1.49% in 2005, 12.72% in 2006 and 11.66% in 2007.

Conclusion: The present data suggest that a significant trend to higher prevalence in patients infected with non-B subtypes was observed and it became more intense for the two last years; however, HIV subtype B is still the most commonly found. On the other hand, comparing between the non-B subtypes we conclude that there are a similar proportion of recombinant and non recombinant non-B sybtypes.

P1013 Structural analysis of the RNA region preceding Gag start codon in HIV-1 type A variants circulating in Russia

I. Lapovok, E. Kazennova, M. Bobkova (Moscow, RU)

Objectives: There are three stem-loops in 5′-untranslated region of HIV-1 RNA playing important roles in viral replication: apical loop of DIS hairpin required for dimerisation of genomic RNA, SD hairpin essential for the generation of subgenomic mRNA and ø hairpin being the major determinant for specific packaging of virus-like particles. These hairpins are located in the region of approximately 100 nt length preceding Gag start codon.

The purpose of the study was to compare the structure of this region in different genetic HIV-1 subtype A variants characteristic for Russia among them the strains carrying the pol gene mutations A62V, V77I, A62V/V77I and no mutations (wild type).

Methods: We have studied 12 samples of PMBC from HIV-infected individuals belonging to four pol gene groups. Prior analysis of genes gag and env found HIV-1 subtype A in these patients. Sequences of the region preceding Gag start codon (650 bp) in nested PCR products were generated.

Results: We have found that the apical loop of DIS hairpin from almost all samples of HIV-1 subtype A in Russia had the same palindrome AG[GUGCAC]A typical for 84% samples of subtype A circulating in the world. The only one sample with A62V mutation characteristic for Russia had the palindrome structure GG[GUGCAC]A. One sample of wild type virus had the palindrome structure AG[GUGCAC]G. There

were no special features in the structure of SD and ø hairpins in Russian samples.
Conclusion: The substitution of A to G in one of three purine residues flanking the palindrome may play the essential role in the forming of structure "kissing-loop" of double genomic RNA of HIV-1. Our data also demonstrate that the structure of SD and ø hairpins is very conservative in HIV-1 subtype A. The structural peculiarities of the apical loop of DIS hairpins can be used in genotyping of virus subtype A.

P1014 Influence of p38 MAPK isoforms (alpha, beta, gamma and delta) in apoptosis induced by HIV-1 in CD4+ T lymphocyte-based cell lines

D. Gutierrez-Sanmartin, E. Varela-Ledo, A. Aguilera-Guirao, S. Romero-Yuste, P. Romero-Jung, A. Gomez-Tato, B.J. Regueiro (Santiago de Compostela, Pontevedra, ES)

Background: The CD4+ T cell reduction characteristic of HIV-1 infection is thought to result, in addition from infected T cell death, mainly from uninfected bystander T cell apoptosis. Nevertheless, the immunologic and virologic mechanisms leading to T cell death during HIV-1 infection are not yet fully understood.
Objective: In the present study we analyse the individual implication of the p38 mitogen-activated protein kinase (MAPK) isoforms (alpha, beta, gamma and delta) in apoptosis induced by HIV-1, taking into account that HIV-1 replication is known to be blocked by p38 inhibitors.
Methods: We used the SupT1 cell line where death induced by HIV-1 mainly happened by uninfected bystander cell apoptosis. A variety of SupT1-based cell lines were constructed constitutively expressing, under the control of cytomegalovirus promoter (PCMV), each dominant-negative p38 isoform and each wild-type p38 isoform as control. An EGFP marker gene, under the control of the HIV-1 promoter, was inserted in all of them. These cell lines were infected with HIV-1 and analysed by flow citometry.
Results: We found that survival in SupT1-based cell lines infected by HIV-1 was increased by dominant-negative p38alpha, p38gamma and p38delta isoforms, but not by the dominant-negative p38beta isoform. HIV-1 replication was delayed most by the dominant-negative p38delta isoform and to a lesser extent by dominant-negative p38alpha and p38gamma isoforms. Moreover, these three dominant-negative isoforms reduced apoptosis induced by HIV-1 in both infected and bystander cells.
Conclusions: These results suggest that, in SupT1 cell line, p38alpha, p38gamma and p38delta, but not p38beta, are implicated in HIV-1 replication and apoptosis induced by HIV-1 in infected and bystander cells.

P1015 HIV-1 induces apoptosis in primary osteoblasts and HOBIT cells through TNF-α activation

M.C. Re, E. De Crignis, C. Ponti, L. Cimatti, M. Borderi, M. Tschon, D. Gibellini (Bologna, Trieste, Italy, IT)

Background: Several HIV-1 infected patients show bone loss and osteopenia/osteoporosis during the course of disease. The mechanisms underlying this degenerative process are largely unsettled and the relantionship between HIV-1 and osteoblasts/osteoclasts cross-talk regulation has not been yet investigated. The aim of our study is focused on analysis of biological effects of HIV-1 on osteoblasts and osteoblast-like HOBIT cells to determine the mechanisms involved in the bone loss in the course of HIV-1 infection.
Methods: Human hipbone osteoblasts of patients were obtained from commercial sources or isolated from HIV-1 negative patients enrolled after giving their informed consent. HIV-1 DNA was determined by PCR whereas RT-PCR was employed to determine viral RNA, cell membrane markers and TNF-a mRNA. Flow cytometry procedures were used for apoptosis and membrane markers analysis. TNF-α supernatant analysis was performed by commercial kit.
Results: Primary osteoblasts and HOBIT osteoblast-like cell line were challenged by specific HIV-1 X4 and R5 strains and proviral HIV-1 PCR analysis showed that these cells are not susceptible to infection. On the other hand, HIV-1, heat-inactivated HIV-1 and HIV-1 gp120 treatment induced a significant apoptotic process activation at 72–96 hours ($p<0.01$) that is tackled by soluble CD4 treatment suggesting an interaction between gp120 and cell membrane proteins. Hence, CD4 and co-receptors membrane protein and mRNA expression was assayed by flow cytometry and real time RT-PCR, respectively, in osteoblasts and HOBIT. Although the CD4 and CXR4 mRNA was costantly detectable in both the cell models, CD4 and CXR4 proteins are expressed at very low density in a low percentage of cells (4–6% and 4% respectively) whereas CCR5 is significantly more expressed. Finally, we analysed the mRNA and protein synthesis of TNF-α a pro-apoptotic factor in osteoblasts biology. HIV-1, heat-inactivated HIV-1 and HIV-1 gp120 treatment induced both the TNF-α mRNA and supernatant protein increase at 24–96 hours. Moreover, anti-TNF-α pretratment tackles the apoptosis induction suggesting a direct role of TNF-α in the HIV-1 related activation of apoptotic process.
Conclusions: These results indicate that HIV-1 triggers apoptosis in osteoblasts and HOBIT cells without infection but through the gp120 interaction with cell membrane suggesting a novel mechanism in the HIV-1 related impairment of the bone mass structure homeostasis

Antifungal treatment and prophylaxis

P1016 Caspofungin as first-line therapy of invasive aspergillosis in haematological patients: impact of baseline characteristics on response rate at end of treatment and survival

J. Maertens, R. Herbrecht, H. Akan, L. Baila, C. Doyen, A. Gallamini, A. Giagounidis, O. Marchetti, R. Martino, L. Meert, M. Paesmans, L. Ameye, M. Shivaprakash, A. Ullmann, C. Viscoli for the Infectious Diseases Group of the EORTC

Caspofungin (C) (70 mg day 1 and 50 mg daily thereafter) was evaluated as first-line therapy of probable/proven IA (first trial ever to strictly adhere to EORTC-MSG criteria) in 61 haematological pts receiving either standard chemotherapy or autologous HSCT (EORTC trial 65041). Confirmation of diagnosis and assessment of efficacy were performed by a Data Review Committee (DRC). The primary efficacy endpoint was the proportion of patients with complete and partial response at the end of C treatment (EOT), defined with standard response assessment criteria. Survival at day 84 was among the secondary endpoints.
In the Modified Intention to Treat analysis (including all patients with proven/probable IA receiving > 1 day of C treatment), 38 of 61 pts (62%) had acute leukaemia (mostly myeloid leukaemia) and 51 (85%) were neutropenic (<500 cells/mm^3) at study entry. Forty-six patients (75%) had uncontrolled cancer. Median age was 64 years (range 19–86). Fifty percent of patients had a Karnofsky score < 50. Median and mean duration of C treatment were 15 and 27 days, respectively (3–84). At EOT, 20 of 61 (33%) pts had a favourable outcome (95% CI 21%–46%), while 9 (15%) and 31 (51%) had stable and worsening disease, respectively. Survival at day 84 was 54% (33 of 61).
The response rate at EOT was not influenced by age, gender, type of underlying haematological disease, status of the underlying disease, certainty of diagnosis of IA, site of infection or presence of baseline neutropenia; however, the median Karnofsky performance score at start of C therapy was higher ($p=0.04$) in patients with a favourable outcome (median 70) compared to patients with an unfavourable outcome (median 50). Similarly, patients with stable disease had a higher performance score ($p=0.02$) compared to those without disease stabilisation.
Survival at day 84 was significantly influenced by the status of the haematological disease at start of C therapy (uncontrolled cancer 40%-controlled cancer 93%; $p<0.001$) and by the Karnofsky score at baseline (15% survival for score <50, 57% for a score 50–60 and 69% for score >60; $p=0.009$).
In conclusion, we identified Karnofsky performance score and status of the underlying haematological disease as significant baseline variables for response at EOT and/or survival at day 84. In future clinical studies

in IA, consideration should be given towards stratification of patients according to these baseline findings.

P1017 **Caspofungin use in daily clinical practice for treatment of invasive aspergillosis: results of a prospective observational registry**

J. Maertens, G. Egerer, W. Shin, D. Reichert, M. Stek, S. Chandwani, M. Shivaprakash, C. Viscoli for the CAN-DO(IA) study team

Objective: To prospectively assess real world experience with Caspofungin (C) administered as monotherapy or in combination therapy for initial or salvage treatment of proven or probable invasive aspergillosis (IA).

Methods: A prospective observational registry was developed to collect data from patients treated with C for a single episode of IA. Information was collected from Apr-06 to Sep-07. Clinical efficacy was determined by the local investigator as favorable (complete or partial) or unfavorable (stable disease or failure) at the end of C therapy (EOCT).

Results: One hundred and three consecutive patients with proven or probable IA (per EORTC/MSG criteria) were identified from 23 sites in 11 countries. Outcomes were assessed in 101/103 patients since 2 patients were not discharged from the hospital at study termination. The most frequent underlying conditions included malignancy (77%), allogeneic hematopoietic stem cell transplantation (HSCT, 20%), solid organ transplantation (SOT, 9%), autologous HSCT (8%), & HIV/AIDS (3%). Neutropenia at start of C was recorded in 57% cases. Eighty three patients (82%) were treated for probable IA. The majority (85%) of patients had pulmonary IA. In culture-proven cases, *A. fumigatus* was the most frequently isolated species followed by *A. flavus*. The majority of patients received C monotherapy (83%), primarily as salvage therapy (86%). Most salvage treatment (74.2%) occurred in patients refractory to prior antifungals. A favorable response at end of C treatment was seen in 56% (57/101) of patients with similar favorable outcomes for C used as combination therapy (56%; 9/16) or as monotherapy (57%; 48/85). Favorable response rates in significant subgroups were: malignancy 52% (41/79); allogeneic HSCT: 57% (12/21); neutropenia: 53% (35/66). Serious adverse events were reported in 4 cases (4%); only 2 patients (2%) discontinued treatment due to a drug related AE (respiratory failure & skin reaction). An overall survival rate of 73%(75/103) was observed at the EOCT.

Conclusions: In daily clinical practice, an overall favorable response rate of 56% was observed in patients with proven or probable IA treated with C monotherapy or combination therapy. Also, a favorable response rate of >50% was seen in high-risk patient sub groups, including those with malignancy, allogeneic HSCT, and neutropenia. These real-life findings are consistent with the findings observed in randomised clinical trials.

P1018 **The use of caspofungin in neutropenic patients with haematological malignancies and concomitant candidaemia**

L. Pagano, L. Fianchi, R. Fanci, A. Candoni, M. Caira, A. Nosari, S. Storti, M. Sanguinetti, M. Morselli, C.G. Valentini, M.E. Mitra, M. Offidani, P. Viale (Rome, Florence, Udine, Milan, Campobasso, Modena, Palermo, Ancona, IT)

Objective: To evaluate the efficacy of caspofungin in neutropenic patients (pts) with hematological malignancies (HM) and candidaemia

Design: The study was conducted in 8 Hematology divisions; neutropenic HM pts with clinical evidence of infection and positive blood culture for *Candida* were enrolled.

Patients and Results: Between January 2005 and November 2007, 22 episodes of candidaemia were registered. All the 22 enrolled patients [M/F 16/6; median age 49 yo (range 19–71)] (11 AML, 4 ALL; 5 NHL, 2 MM) had received chemotherapy. Nine of them (41%) developed candidaemia during a HSCT procedure (6 allogeneic and 3 autologous). Before the infection onset and at start of caspofungin, all pts were neutropenic (ANC$<0.5\times10^9$/l) for a median average of 5 days (range 2–41). Other risk factors were: CVC (77%), steroids administration (41%), mucositis (73%), diabetes (13%), *Candida* colonisation (36%). Nine pts (41%) received systemic antifungal prophylaxis (5 fluconazole, 2 itraconazole, 2 voriconazole) for an average of 13 days (4–60). The most frequent symptoms were: fever (100%), dyspnoea (27%), jaundice (13%), diarrhoea (13%), shock (13%). Candidaemia diagnosis was made after a median time of 3 days (range 1–12) from the onset of fever; *Candida* species isolated were: *albicans* 9 pts (41%), *parapsilosis* 4 (18%), *krusei* 3 (14%), *tropicalis* 2 (9%), *dubliniensis* 1 (4.5%), *guilliermondii* 1 (4.5%), *famata* 1 (4.5%), *lusitaniae* 1 (4.5%). Caspofungin at standard dosage was administered as front-line treatment in 16 pts (73%); in the other 6 pts, previous antifungal therapy (3 L-AmB, 1 itraconazole, 1 fluconazole, 1 voriconazole) was switched to caspofungin after no more than 48 hours on treatment at candidaemia diagnosis. The median duration of caspofungin therapy was 13 days (range 6–26). No side effects (WHO >2) were registered. Antifungal treatment was efficacious with remission of fever and other symptoms and negative blood cultures in 15 pts (68%). At 30 days following candidaemia onset, 9 pts had died (41%), but the candidaemia was responsible for the mortality in only 4 pts (overall attributable mortality 18%).

Conclusions: Our data, reporting the largest series of neutropenic HM pts and concomitant candidaemia treated with caspofungin. This study confirms the efficacy and safety of this approach in a subset of very compromised pts similar to that reported in literature in non neutropenic pts.

P1019 **Efficacy and safety of caspofungin monotherapy in cancer patients with candidaemia**

N.V. Sipsas, R.E. Lewis, I.I. Raad, D.P. Kontoyiannis (Houston, US)

Objective: There is a paucity of data regarding the efficacy and safety of caspofungin (CAS) in cancer patients with candidaemia.

Methods: We retrospectively reviewed the medical records of all adult cancer patients with candidaemia (EORTC criteria) treated with CAS monotherapy for at least 3 consecutive days at MD Anderson Cancer Center (March 2001-February 2007). CAS was given intravenously at 50 mg /day after a 70 mg loading dose. Demographic characteristics, clinical and microbiological data, outcomes, minimal inhibitory concentrations (MIC) of *Candida* isolates (CLSI method), were recorded.

Results: We identified 65 such patients (20 or 31% had hematological malignancies). The clinical response and mycological response after 7 days of CAS was 80% (51 patients) and 78% respectively. The overall mortality was 5% for day 7, 12% for day 14, and 20% for day 30. The 30-day *Candida*-attributable mortality was 11%. Bivariate analysis showed that factors significantly associated with crude 30 day mortality were an APACHE II score >20, ICU admission, a positive culture of the tip of the removed central venous catheter, especially when CFU/ml was > 15, persistent fungaemia after initiation of treatment, and the presence of intercurrent bacterial infection. The 30 day attributable mortality in the 12 patients (18%) with fluconazole-resistant or susceptible-dose dependent *Candida* bloodstream isolates (MIC $\geqslant 8\,\mu$g/ml) was 25% vs. 8% in the 53 patients with fluconazole-susceptible *Candida* ($p < 0.05$). CAS was well tolerated.

Conclusion: Although selection of candidemic cancer patients who received CAS monotherapy might account for the observed favorable outcomes, in our experience CAS had comparable efficacy and safety to the ones described in candidemic patients without malignancy.

P1020 **Prospective, multicentre study of caspofungin for treatment of documented fungal infections in paediatric patients**

T. Zaoutis, H. Jafri, L. Huang, F. Locatelli, A. Barzilai, W. Ebell, W. Steinbach, J. Bradley, J. Lieberman, C. Hsiao, N. Seibel, H. Laws, M. Petrecz, A. Taylor, J. Chow, N. Kartsonis, A. Ngai (Philadelphia, Dallas, US; Taipei, Kaohsiung, TW; Pavia, IT; Tel Hashomer, IL; Durham, San Diego, Long Beach, Washington, West Point, US; Berlin, Dusseldorf, DE)

Objective: A prospective open-label study was performed to obtain data on the efficacy & safety of caspofungin (CAS) in paediatric patients (ped pts) with invasive candidiasis (IC), oesophageal candidiasis (EC), or invasive aspergillosis (IA).

Methods: Ped pts ages 3 mos-17 yrs with proven IC, proven EC, or proven/probable IA (EORTC/MSG criteria) received CAS at 50 mg/m2 daily (70 mg/m2 on Day 1) as either primary or salvage monotreatment (max 70 mg/day). Favourable responses required complete resolution of clinical findings & microbiological (or radiographic/endoscopic) eradication (complete response) or significant improvement in these parameters (partial response). The primary efficacy assessment was at end of CAS treatment (EOT) and included pts with a confirmed diagnosis and receipt of atleast 1 dose of CAS.

Results: Of the 49 pts (33 at 6 mos-11 yrs & 16 at 12–17 yrs) enrolled, 48 had confirmed disease: 37 IC, 1 EC, & 10 IA. Most IC pts (35/37) had candidaemia & received CAS as primary treatment (31/37). Most pts with IA had pulmonary involvement (8/10, including 2 with >1 site of infection). All pts with IA were refractory & received CAS as salvage treatment. CAS was dosed for 2–87 days (median 10 & 38 days for IC & IA, respectively). Success at EOT was 30/37 (81%) in IC, 1/1 in EC, & 5/10 (50%) in IA. IC outcomes were generally similar across *Candida* spp. No pt developed a serious drug-related adverse event or discontinued CAS due to toxicity. All-cause mortality during treatment or the 4-week posttreatment follow up period was 10%.

Conclusions: In this study, CAS was effective & generally well tolerated in peds pts with IA or IC. Outcomes in peds pts are consistent with those reported in adults.

P1021 **Efficacy of caspofungin compared to itraconazole as secondary antifungal prophylaxis: a multinational case registry**

J. Vehreschild, M. Sieniawski, S. Reuter, D. Reichert, J. Maertens, A. Böhme, G. Silling, R. Martino, G. Maschmeyer, A. Ullmann, O. Cornely (Cologne, Ulm, Oldenburg, DE; Leuven, BE; Frankfurt, Münster, DE; Barcelona, ES; Potsdam, Mainz, DE)

Background: Patients surviving an invasive fungal infection (IFI) in need of further cytoreductive chemotherapy are at high risk for recurrent fungal infection. In the absence of randomised controlled trials on this issue, applied prophylactic regimens are diverse and rely primarily on the personal experience of the attending physician.

Methods: A multinational case registry of patients in need of secondary antifungal prophylaxis has been conducted from October 2001 onwards. Patients with leukaemia or high-grade lymphoma and a history of probable or proven IFI according to EORTC/MSG criteria were analysed if undergoing an additional episode of neutropenia and receiving prophylaxis with either itraconazole or caspofungin. Data collected comprise demographics, underlying disease, first episode of IFI, antifungal prophylaxis, incidence and outcome of breakthrough IFI, and survival.

Results: A total of 75 patients were evaluated, 47 receiving itraconazole and 28 receiving caspofungin. Age, gender, underlying malignancy, type and treatment of 1st IFI, and isolation measures were evenly distributed between both groups. Treatment of underlying disease more often was stem cell transplantation in the caspofungin group (21.3% vs 50%, P= 0.01). There were more patients with liver (0% and 25%, P = 0.001) or spleen (0% and 14%, P = 0.017) involvement of 1st IFI, with uncontrolled 1st IFI (0% and 10.7%, P = 0.049), or uncontrolled malignancy (8.5% and 32.1%, P = 0.012) in the caspofungin group. No significant difference for the occurrence of probable or proven breakthrough IFI (17.0% and 28.6%, P = 0.186) was observed. Treatment outcomes for recurrent IFI and underlying disease were similar between both groups. Mortality attributable to IFI (4.3% and 3.6%) and overall mortality (10.6% and 25%) were not different between both groups.

Conclusion: Both, itraconazole and caspofungin performed equally efficacious as secondary prophylaxis of IFI in high-risk patients. While there was a trend towards higher risk of recurrent IFI and death in the caspofungin group, these patients were at significantly higher risk probably influencing the choice of drug: They had a higher rate of uncontrolled fungal and underlying diseases and underwent stem cell transplantation more frequently. In spite of antifungal prophylaxis, risk of breakthrough IFI was high. Prospective controlled trials are warranted to define the best strategy of secondary antifungal prophylaxis.

P1022 **Efficacy and safety of micafungin for treatment of serious *Candida* infections in patients with or without malignant disease**

O.A. Cornely, F.M. Marty, P.G. Pappas, A.J. Ullmann (Cologne, DE; Boston, Birmingham, US; Mainz, DE)

Objectives: To evaluate the efficacy of micafungin for the treatment of invasive candidiasis/candidaemia in patients classified as having malignancy versus no malignancy at baseline.

Methods: Data (modified intent-to-treat population) were analysed from two phase III, multicentre, randomised trials conducted in patients with confirmed *Candida* infection at baseline. One trial, in adults and children, compared micafungin (adults: 100 mg/day; children: 2 mg/kg/day) with liposomal amphotericin B (L-AmB; 3 mg/kg/day); the other, in adults only, compared micafungin (100 mg/day and 150 mg/day) with caspofungin (50 mg/day; 70 mg loading dose). In both trials, the primary efficacy endpoint was treatment success at end of therapy, defined as both a positive clinical and positive mycological response.

	Treatment success at end of therapy, n/Nº (%)				
	MICA n = 244	L-AmB n = 245	MICA100 n = 191	MICA150 n = 199	CAS n = 188
No Malignancy	118/157 (75.2)	107/149 (71.8)	95/123 (77.2)	109/143 (76.2)	99/136 (72.8)
Malignancy	62/87 (71.3)	69/96 (71.9)	51/68 (75.0)	33/56 (58.9)	37/52 (71.2)
– without neutropenia	41/53 (77.4)	48/62 (77.4)	34/48 (70.8)	24/39 (61.5)	31/43 (72.1)
– with neutropenia	21/34 (61.8)	21/34 (61.8)	17/20 (85.0)	9/17 (52.9)	6/9 (66.7)

MICA: micafungin 100 mg/day in adults and 2 mg/kg/day in children; MICA 100: micafungin 100 mg/day; MICA 150: micafungin 150 mg/day; L-AmB: liposomal amphotericin B 3 mg/kg/day; CAS: caspofungin 50 mg/day with 70 mg loading dose.

Results: In the micafungin/L-AmB trial, there were 183 patients with malignancy (37% were neutropaenic) and 306 with no malignancy. In the micafungin/caspofungin trial, there were 176 patients with malignancy (26% were neutropaenic) and 402 with no malignancy. Key efficacy findings are shown in the table. In general, rates for treatment success with micafungin were similar in patients with and without malignancy and were similar to rates observed with L-AmB and caspofungin, although in one group (patients with malignancy, micafungin 150 mg/day, caspofungin comparator trial) treatment success was lower than in other groups (P = 0.15). Most patients with malignancy and neutropenia were successfully treated by all three drugs, although with the exception of patients receiving micafungin 100 mg in the caspofungin comparator trial, rates were lower (non-significantly) than in non-neutropaenic patients with malignancy. For all three drugs, the incidence of discontinuations due to treatment-related adverse events (AEs) was similar for patients with malignancy (⩽7.7%) versus no malignancy (⩽8.0%). In the L-AmB comparator trial, a smaller proportion of the total population discontinued therapy due to treatment-related AEs with micafungin (4.9%) versus L-AmB (7.9%). In the

caspofungin comparator trial, comparative values were 2.5%, 3.0%, and 3.6% for micafungin 100 mg, micafungin 150 mg, and caspofungin 50 mg, respectively.

Conclusion: Micafungin was effective and well tolerated in patients with or without malignancy. Micafungin is shown to be a valuable therapeutic option for the treatment of invasive candidiasis and candidaemia across a broad range of patients.

P1023 Pooled analysis of safety for micafungin

O.A. Cornely, P.G. Pappas, J.A. Young, P. Maddison, A.J. Ullmann (Cologne, DE; Birmingham, Minneapolis, US; Leiderdorp, NL; Mainz, DE)

Objectives: Micafungin (MICA) efficacy has been demonstrated in different patient populations [1–4]. To better understand the safety profile of MICA, a pooled analysis of clinical trial safety data was undertaken.

Methods: We analysed safety data collected from 15 clinical trials conducted worldwide. Adverse events (AEs) were coded using MedDRA 5.0. All patients (N=2653) received ⩾1 dose of intravenous MICA at a median daily dosage of 100 mg (range: 8.9–896 mg) for adults (aged 16–92 yrs) and 1.5 mg/kg (range: 0.4–4.7 mg/kg) for children (aged 0 wks-15 yrs), over a mean duration of 15 and 17 days, respectively.

Results: Mean subject age was 41.5 yrs (SD ± 18.7 yrs) including 226 (8.5%) children (<16 yrs) and 336 (12.7%) elderly patients (⩾65 yrs). Common underlying conditions were HIV (37.2%), haematopoietic stem cell or other transplantation (23.7%), and solid tumour or severe organ disorder (11.0%). Frequently reported MICA-related AEs (⩾2%) included phlebitis (2.8%), nausea (2.6%), vomiting (2.5%), hypokalaemia (2.2%), pyrexia (2.2%), and increases in alkaline phosphatase (2.6%), aspartate aminotransferase (2.5%) and alanine aminotransferase (2.0%). In comparative studies, the MICA safety profile was superior to liposomal amphotericin B, and similar to fluconazole and caspofungin (table).

Adverse event	Candidaemia/Invasive Candidiasis		Candidaemia/Invasive Candidiasis			Oesophageal candidiasis‡		Prophylaxis†	
	MICA 100 mg (n=316)	AmB 3 mg/kg (n=321)	MICA 100 mg (n=200)	MICA 150 mg (n=202)	CASPO 50 mg# (n=193)	MICA 150 mg (n=260)	FLU 200 mg (n=258)	MICA 50 mg (n=425)	FLU 400 mg (n=457)
Hypokalaemia	21 (6.6%)×	38 (11.8%)	4 (2.0%)	5 (2.5%)	3 (1.6%)	1 (0.4%)	1 (0.4%)	8 (1.9%)	8 (1.8%)
Pyrexia	23 (7.3%)×	39 (12.1%)	2 (1.0%)	0	1 (0.5%)	5 (1.9%)	1 (0.4%)	4 (0.9%)	5 (1.1%)
Rigours	2 (0.6%)×	19 (5.9%)	1 (0.5%)	2 (1.0%)	1 (0.5%)	6 (2.3%)	0	1 (0.2%)	5 (1.1%)
Creatinine increased	6 (1.9%)×	17 (5.3%)	0	1 (0.5%)	1 (0.5%)	0	0	1 (0.2%)	3 (0.7%)
Infusion-related event	52 (16.5%)×	87 (27.1%)	5 (2.5%)	0	5 (2.6%)	9 (3.5%)	8 (3.1%)	2 (0.5%)	4 (0.9%)

Treatment-related: assessed by investigator as having at least a possible relationship to study drug.
AmB: liposomal amphotericin B; CASPO: caspofungin; FLU: fluconazole; MICA: micafungin.
† Haematopoietic stem cell transplantation (HSCT) was the main inclusion criterion.
‡ Most oesophageal candidiasis (OEC) patients were HIV positive with AIDS.
× $P < 0.05$, Fisher's exact test.
After a 70 mg loading dose.

Conclusions: This large database with more than 2650 patients demonstrates that MICA has a favourable clinical safety profile.

P1024 Multivariate logistic regression modelling of variables associated with treatment outcomes from two large, prospective micafungin registrational trials

D.L. Horn, O.A. Cornely, M.I. Morris, A.J. Ullmann, C. Wu, L.L. Kovanda, D.N. Buell (Philadelphia, US; Cologne, DE; Miami, US; Mainz, DE; Deerfield, US)

Objectives: Two recent, large, prospective micafungin trials in patients (pts) with candidaemia and invasive candidiasis reported: (1) micafungin 100 and 150 mg were non-inferior to caspofungin (CID 2007;45:883; study 03–0–192), (2) micafungin was as effective as liposomal amphotericin B, with fewer adverse events (Lancet 2007;369:1519; study FG-463–21–08). Further analyses were undertaken to identify variables associated with overall treatment outcomes in adults.

Methods: Separate models were created for 03–0–192 (578 pts) and FG-463–21–08 (492 pts). Potential explanatory variables were age, gender, region, infection type, neutropenia status, baseline steroids, APACHE II score, catheter status, *Candida* spp., and baseline condition. Overall treatment success at the end of IV therapy (Rx) was defined as clinical and mycological success. Point estimates and 95% confidence intervals (CI) for the comparative odds for each variable were calculated.

Results: In 03–0–192, catheter removal, region, baseline APACHE II score, infection type, age group, and steroids had significant effects on treatment outcome (p = 0.0023, 0.0001, 0.001, 0.031, 0.041, 0.003, respectively). Odds ratio (OR) analyses demonstrated significantly less likelihoods to achieve treatment success for: (1) Pts without catheter removal (OR = 0.49, 95% CI = 0.31, 0.78), (2) Pts treated in India vs those in North America (OR = 0.14, 95% CI = 0.06, 0.29), (3) Pts with a baseline APACHE II score of >20 to ⩽30 or >30 vs ⩽20 (OR = 0.42 and 0.28, 95% CI = 0.24, 0.72 and 0.10, 0.77), (4) Pts with disseminated infection (OR = 0.36, 95% CI = 0.14, 0.91), (5) Pts ⩾70 yrs vs <50 (OR = 0.46, 95% CI = 0.25, 0.84), (6) Pts receiving steroids (OR = 0.50, 95% CI = 0.31, 0.79).

In FG-463–21–08, baseline APACHE II score and neutropenia status during Rx had significant effects on treatment success (p = 0.0001, 0.003). OR analyses demonstrated significantly less likelihoods to achieve success with: (1) A baseline APACHE II score of >20 to ⩽30 or above 30 vs ⩽20 (OR = 0.51 and 0.09, 95% CI = 0.30, 0.87 and 0.03, 0.27), (2) Neutropenia (OR = 0.32, 95% CI = 0.15, 0.68).

Conclusion: In both micafungin trials, pts with high APACHE II scores were less likely to have treatment success. Additionally, pts in 03–0–192 were less likely to achieve success if they did not have removal of catheters, were receiving Rx in India, had disseminated infection, were ⩾70 yrs, or were receiving steroids. Neutropenic pts in FG-463–21–08 were less likely to achieve treatment success.

P1025 Economic analysis of micafungin versus liposomal amphotericin B for treatment of candidaemia and invasive candidiasis in the UK

G. Park, M. Sidhu, A. van Engen, O. Schoeman (Cambridge, Staines, UK; Hoofddorp, NL)

Objectives: To investigate the economic impact of introducing micafungin (MICA) (Mycamine®) for the treatment of systemic candida infections (SCIs) (including invasive candidiasis and candidaemia), a health economic analysis was performed comparing MICA with liposomal amphotericin B (L-AMB) (AmBisome®).

Methods: The model was based on observations and time-points from a phase III, randomised, double-blind, clinical trial which compared MICA with L-AMB[1]. The model (originally developed for Germany) entails a period of 14–20 weeks starting from initiation of treatment and was analysed from a UK hospital perspective. Hospitalisation and primary medication costs were included in the current analysis. Unit costs of these resources were taken from appropriate UK costing sources. As the price for MICA was not available at the time of analysis, the price per recommended daily dose (RDD) of MICA (100 mg) was assumed to be equal to the price per RDD of caspofungin (50 mg). The model

endpoint was defined as the percentage of patients that achieved complete or partial clinical and mycological response after initial treatment, and were alive after the 12-week follow-up period. The model was analysed using two methods: a cohort simulation and a probabilistic simulation (i.e., Second-Order Monte Carlo [MC] simulation).
Results: The health economic analysis shows that with MICA 52.9% of patients were successfully treated and survived 12 weeks after treatment ends compared to 49.1% for L-AMB (see Table 1). In addition, MICA was, on average, less expensive than L-AMB costing £ 26,838 and £ 29,549 per patient, respectively

Table 1: Summary of results

Outcome	Treatment strategy	
	MICA	L-AMB
Average cost per patient		
Medication	£5,812	£6,580
Hospitalisation	£21,026	£22,969
Total	£26,838	£29,549
Effectiveness*	52.9%	49.1%
C/E	£50,755	£60,197
Incremental C/E ratio	L-AMB is dominated by MICA	

*% of patients that are succesfully treated and alive after 12 weeks.

Because the costs are lower and the effectiveness is higher for MICA (cost-effectiveness [C/E] ratio = £ 50,755) in comparison with L-AMB (C/E ratio = £ 60,197), MICA dominates L-AMB from a cost-effectiveness point-of-view. The results of the MC simulation and the sensitivity analyses showed that MICA remained the most cost-effective option throughout the analyses, although considerable variance in treatment-associated costs was observed for both treatment options.
Conclusions: The lower costs and higher effectiveness reported for MICA versus L-AMB in this analysis indicate MICA is the more cost-effective therapy in the treatment of SCIs when compared to L-AMB.

Reference(s)

[1] Kuse ER, Chetchotisakd P, da Cunha CA, et al. Micafungin versus liposomal amphotericin B for candidaemia and invasive candidosis: a phase III randomised double-blind trial. Lancet 2007;369(9572):1519–27

P1026 An evaluation of hospital length of stay in intensive care patients with invasive candidiasis treated with anidulafungin versus fluconazole

D. Kett, A. Reboli, C. Rotstein, A. Shorr, S. Gasper, H. Schlamm (Miami, Camden, Washington, New York, US; Hamilton, CA)

Objectives: Invasive *Candida* infections in critically ill patients are associated with high attributable mortality and significant healthcare costs. The most significant cost results from an increased hospital length of stay (LOS) (Rentz et al). Although a number of antifungal drugs are available to treat these infections, few studies have compared the mean LOS associated with these agents. The objective of this study was to compare intensive care unit (ICU) and total hospital LOS in ICU patients receiving anidulafungin (ANID) versus fluconazole (FLU) for treatment of invasive candidiasis.
Methods: Data from patients confirmed to be in the ICU on day of entry into a phase 3, randomised double-blind study comparing intravenous (IV) ANID (200 mg Day 1, then 100 mg daily) and IV FLU (800 mg Day 1, then 400 mg daily) for treatment of invasive candidiasis (Reboli et al) were retrospectively analysed. ICU and total hospital LOS were determined for all eligible ICU patients and for those who survived to 2 weeks after end of treatment (EOT).
Results: Sixty-three of the 245 patients in the primary analysis population of the study were confirmed to be in the ICU at study entry (ANID, n = 35; FLU, n = 38). In this group, the mean ICU LOS was 23.4 ± 24.1 days for ANID versus 29.3 ± 26.2 days for FLU (difference, −5.9 days; 95% CI, −18.7 to 6.8), and the mean total hospital LOS was 32.6 ± 23.7 days for ANID versus 39.3 ± 29.9 days for FLU (difference, −6.6 days; 95% CI, −20.1 to 6.9). Fifty-four of the 63 ICU patients survived to 2 weeks after EOT (ANID, n = 32; FLU, n = 32). In this group, the mean ICU LOS was 24.8 ± 24.7 days for ANID but increased to 34.9 ± 27.0 days for FLU (difference, −10.1 days; 95% CI, −24.3 to 4.2), and the mean total hospital LOS was 34.9 ± 23.4 days for ANID compared with 47.3 ± 28.8 days for FLU (difference, −12.4 days; 95% CI, −26.7 to 1.9).
Conclusion: In ICU patients with invasive candidiasis, ANID treatment was associated with shorter ICU and total hospital LOS compared with FLU treatment, and these differences were more pronounced in patients who survived for 2 weeks after EOT. These numerical differences in LOS will likely have financial implications given the expense associated with prolonged hospitalisation and ICU usage.

P1027 Cost-effectiveness of posaconazole versus standard azole treatment (fluconazole or itraconazole) in the prevention of invasive fungal infections among high-risk neutropenic patients in Spain

S. Grau, R. de la Cámara, M. Sanz, E. Carreras, I. Jarque, M.A. Casado, F.J. Sabater, G. Papadopoulos (Barcelona, Madrid, Valencia, ES; Kenilworth, US)

Background: Posaconazole (POS) has demonstrated to be superior to standard azole therapy (SAT; fluconazole or itraconazole) in preventing both invasive fungal infections (IFIs) and reducing overall mortality among high-risk neutropenic patients (Cornely 2007).
Objectives: To evaluate the cost-effectiveness of POS compared with SAT for the prevention of IFIs among patients with acute myelogenous leukaemia (AML) or myelodysplastic syndromes (MDS) who are at high-risk of developing an IFI due to chemotherapy-induced neutropenia.
Methods: A decision-analytic model was used to predict the likelihood of IFI and death, using published data from the Cornely trial. Patients in the model were assumed to have received prophylaxis with POS or SAT (fluconazole, 81%; itraconazole, 19%). Clinical results were extrapolated to lifetime horizon by extending the model with 1-month Markov cycles including specific mortality risk for underlying diseases. Model outcomes include IFIs avoided, life-years saved, total costs, incremental cost per IFI avoided, and incremental cost-effectiveness ratio (ICER; incremental cost per life year saved) of POS versus SAT over a lifetime. The analysis was done from the perspective of the Spanish HealthCare System. Data on life expectancy were obtained from Spanish Statistics Institute. Information on medical procedures was obtained from the Cornely study and an expert committee. Costs for IFI treatment and drug/administration costs were taken from published literature (€2007 values). A deterministic and probabilistic sensitivity analyses (PAS) were performed.
Results: POS is associated with fewer IFIs (0.05 versus 0.11 p = 0.003), increased life years (2.52 versus 2.43), and (excluding costs of the underlying condition) significantly lower costs (€5,911 versus €7,475) per patient relative to SAT over a lifetime horizon. Results from the PSA indicate that there is an 87% probability that POS is a cost-saving strategy versus SAT and that the probability that the ICER ratio for POS versus SAT is below an estimated €30,000 per life year saved threshold is 98%.
Conclusion: Posaconazole has been shown to be more effective than standard azole therapy in preventing IFIs and reducing overall mortality in high-risk neutropenic patients. An incremental cost-effectiveness analysis done from the perspective of the Spanish HealthCare System, has indicated the dominance (lower costs and greater efficacy) of posaconazole versus fluconazole or itraconazole.

P1028 Cost-effectiveness of posaconazole vs. fluconazole in the prevention of invasive fungal infections among patients with graft-versus-host disease in Spain

S. Grau, R. de la Camara, E. Carreras, M.A. Sanz, I. Jarque, M.A. Casado, F.J. Sabater, G. Papadopoulos (Barcelona, Madrid, Valencia, ES; Kenilworth, US)

Background: Ullman et al. (NEJM 2007) had shown in a recent clinical trial that posaconazole (POS) is similar to fluconazole (FLU) in the prevention of invasive fungal infections (IFIs) among allogeneic hematopoietic stem-cell transplant (HSCT) patients with graft-versus-host disease (GVHD).
Objectives: To assess the cost-effectiveness of POS versus FLU in preventing IFI in patients with GVHD from the Spanish National Health System perspective.
Methods: A decision-analytic model was developed to assess the average per patient treatment costs, IFIs avoided, life-years gained, and incremental cost per life-year gained of each prophylactic treatment (€ 2007). The trial results were extrapolated to a lifetime horizon by extending the model with one-month Markov cycles including specific mortality risk for GVHD. Patients are assumed to receive POS or FLU; probability of IFI, IFI-related death and death from other causes were obtained from the published clinical trial. Long-term mortality and prophylaxis drug and IFI treatment costs were estimated from secondary sources. One-way and probabilistic sensitivity analyses were conducted.
Results: preliminary results shows that POS is associated with fewer IFIs (0.05 vs. 0.09), increased life years (8.01 vs. 7.78), and higher IFI-related costs (prophylaxis and IFI treatment) (€11.585 vs. €6.959) per patient relative to FLU over a lifetime horizon. Costs for treatment of IFIs comprised 82% of the total cost for FLU and 29% for POS. The incremental cost-effectiveness of POS versus FLU is estimated to be €20.246 per life-year saved. Results are most sensitive to changes in the cost of preventing an IFI and the efficacy of prophylaxis. A second-order probabilistic Monte Carlo sensitivity analysis was conducted to assess the effects of parameter uncertainty on the study findings, particularly as relates to treatment efficacy and the costs of preventing an IFI. Results indicate that there is a 70% probability that POS is cost-effective at a €30.000 per life year saved threshold, threshold commonly used in Spain for assessing the cost-effectiveness of new technologies.
Conclusion: Based on this analysis, we conclude that posaconazole is a cost-effective strategy in Spain for the prevention of IFIs among patients with GVHD.

P1029 Posaconazole versus standard azole therapy in the prophylaxis against invasive fungal infections among high-risk neutropenic patients in Canada: a cost-effectiveness analysis

A.A. Tahami Monfared, A.K. O'Sullivan, G. Papadopoulos (Kirkland, CA; Medford, Kenilworth, US)

Objective: Posaconazole has been demonstrated to be significantly superior to standard azole therapy (i.e., fluconazole or itraconazole) in preventing invasive fungal infections (IFIs) ($P<0.001$) and in reducing overall mortality ($P=0.048$) among patients with haematological malignancy with prolonged neutropenia (Cornely et al. NEJM, 2007). The objective of this study was to assess the cost-effectiveness of posaconazole in this patient population from the perspective of the Canadian healthcare system.
Methods: A decision-analytical model based on trial results was developed. Patients in the model were assumed to receive prophylaxis with posaconazole or standard azole therapy (fluconazole, 81%; itraconazole, 19%). The probabilities of experiencing an IFI, IFI-related death, and death from other causes over 100 days of follow-up were estimated from the trial data. To extrapolate results beyond the trial period, the model was extended to a lifetime horizon using 1-month Markov cycles in which mortality rate is specific to the underlying disease as estimated from Statistics Canada and Surveillance, Epidemiology, and End Results (SEER) program data. Long-term mortality, drug costs, and IFI treatment costs were estimated using published literature. The model was used to estimate costs, IFIs avoided, life-years gained, and the incremental cost-effectiveness ratio (ICER) of posaconazole versus standard azole therapy (using 2007 Canadian dollars).
Results: Posaconazole is associated with fewer IFIs (0.05 vs. 0.11) ($P=0.003$), increased life-years (0.744 vs. 0.728), and (excluding costs of the underlying condition) slightly lower costs ($7,147 vs. $7,332) per patient relative to standard azole therapy over a lifetime horizon. A second-order probabilistic Monte Carlo sensitivity analysis was conducted to assess the effects of parameter uncertainty on the study findings, particularly as they relate to treatment efficacy and the costs of an IFI. Results indicate that there is a 53% probability that posaconazole is cost saving versus standard azole therapy and a 70% probability that the ICER for posaconazole is at or below the $50,000 per life-year saved threshold.
Conclusion: In addition to the proven efficacy, posaconazole appeared to be cost saving relative to standard azole therapy (i.e., fluconazole or itraconazole) in the prevention of IFIs among high-risk neutropenic patients.

P1030 Economic evaluation of posaconazole compared with other systemic fungal therapies in patients with refractory invasive aspergillosis in Canada

A.A. Tahami Monfared, S. Rajagopalan, R. Danna, G. Papadopoulos (Kirkland, CA; Williamsville, Morristown, Kenilworth, US)

Objective: To evaluate all-cause mortality and cost of treatment in patients with refractory invasive aspergillosis (rIA) treated with either posaconazole or other systemic anti-fungal (SAF) therapies.
Methods: All-cause mortality and cost of salvage therapy of posaconazole oral suspension (800 mg/day) and other SAF treatments were assessed using an open-label, multicentre, externally controlled study in patients with invasive aspergillosis who were refractory to or intolerant of conventional antifungal therapy. Data from external control cases were collected retrospectively to provide a comparative reference group. All patients had failed to improve or progress with prior antifungal therapy. Prior antifungal therapies for the majority of patients were liposomal amphotericin B, amphotericin B, or itraconazole. Cases of aspergillosis deemed evaluable by a blinded data review committee included 107 posaconazole recipients and 86 control subjects (modified intent-to-treat population). The populations were similar and balanced with regard to pre-specified demographic and disease variables. All-cause mortality were analysed using the survival technique. Cost analysis was censored at day 372. Economic evaluation were conducted using survival data and costs of pharmacotherapy (estimates are based on 2007 Canadian dollars).
Results: Significantly more patients who were treated with posaconazole responded to therapy compared with similar patients treated with other salvage therapies. Patients with rIA treated with posaconazole appeared to confer a highly significant survival benefit over the control cases. The cumulative rates of survival at 30 days and at the end of therapy were 74% and 38%, respectively; for control subjects, those survival rates were 49% and 22%, respectively. The Kaplan-Meier survival curve was significantly different ($P=0.0003$). In addition, posaconazole appears to be a "dominant" (i.e., cost saving) option for the treatment of refractory aspergillosis when compared to the active comparator receiving standard antifungal salvage therapies ($14,839 vs. $38,158). Sensitivity analyses demonstrated that the cost savings observed were maintained over a range of alternative values for costs and outcomes.
Conclusions: Treatment with posaconazole as compared with other systemic anti-fungal therapies provided a significant survival benefit in patients with rIA at lower cost of drug therapy.

P1031 **Pharmaco-economic analyis of posaconazole versus standard azole prophylaxis in high-risk neutropenic AML/MDS patients in Germany**

M. Thalheimer, O.A. Cornely, T. Hoppe-Tichy, U. Schuler, H. Knoth, M. Kiehl, A.J. Ullmann, A. O'Sullivan, H. Ostermann (Heidelberg, Cologne, Dresden, Frankfurt/Oder, Mainz, DE; Medford, US; Munich, DE)

Objectives: The objective of our analysis was to estimate the cost-effectiveness of antifungal prophylaxis with posaconazole vs. standard azole therapy (i.e., fluconazole or itraconazole) in patients with acute myelogenous leukaemia (AML) or myelodysplastic syndrome (MDS) and at high risk of developing an IFI due to chemotherapy-induced neutropenia. Posaconazole significantly prevents invasive fungal infections (IFIs) and reduces overall mortality vs. standard azole therapy in these patients (Cornely et al. NEJM, 2007).

Methods: A decision-analytic model was developed based on the results of the large multicentre trial, extrapolated to a lifetime horizon and analysed from a German perspective.

The probabilities of experiencing an IFI, IFI-related death, and death from other causes over 100 days of follow-up were estimated from the trial data. Long-term mortality data is based on the database of a large German university clinical centre, drug costs were estimated using published sources. IFI treatment costs were derived from a multicentre retrospective chart review. Due to a lack of published data on the impact of an IFI on quality of life of AML/MDS patients, a panel of 20 hematology-oncology experts estimated this impact based on the SF-6D questionnaire. The utilities derived from the analysis of the questionnaires served to estimate the quality-adjusted life years (QALY). The pharmacoeconomic model presented was used to estimate incremental cost per patient, incremental cost-effectiveness ratio (ICER) per life-years saved and incremental costs per quality-adjusted life years (QALY).

Results: Posaconazole is associated with fewer IFIs (0.05 vs. 0.11; p = 0.003) and slightly higher overall treatment costs (1,041 €) per patient relative to standard azole therapy over a lifetime horizon. The ICER per live-years saved was 10,235 €. Posaconazole prophylaxis resulted in 0.1 QALYs gained in comparison to prophylaxis with standard azoles. Results from a probabilistic sensitivity analysis indicate that there is an 81% probability that the cost per QALY gained with posaconazole is below 20,000 €, a commonly accepted threshold for cost-effectiveness.

Conclusion: Based on the clinical data and on the assumptions, our analysis demonstrated that posaconazole is likely to be cost-effective relative to standard azole therapy (i.e., fluconazole or itraconazole) in the prevention of IFIs among high-risk neutropenic patients.

P1032 **Retrospective, multicentre, pharmaco-epidemiological study of the administration of liposomal amphotericin B in patients admitted to intensive care units**

F. Alvarez-Lerma, F. Mariscal, E. Quintana, G. Rialp, J. Díaz, M. Pérez, B. Alvarez, I. Ausín and the Study Group for Liposomal Amphotericin B in ICU

Objective: To analyse the indications and posology of liposomal amphotericin B (L-AMB) in patients admitted to intensive care units (ICUs).

Methods: Retrospective, multicentre and observational study of patients admitted to ICUs and treated with L-AMB for any reason in 2006. Invasive fungal infections (IFIs) were classified as proven, probable or possible. Treatment indications were classified as first line or as rescue treatment.

Results: 179 patients were included and 30 ICUs participated. Mean APACHE II score was 20.9 (SD:7.9), mean length of ICU stay was 28.6 (SD: 24.0) days and intra-ICU mortality rate was 43.4%. Most common pathologies were medical pathology (45.3%) and surgery (34.1%) and 68.2% of the patients had severe sepsis or septic shock. Invasive fungal infections were proven, probable and possible in 43.6%, 15.6%, and 25.1% of cases, respectively and not classified in the remaining 15.7%. Aetiology: *Candida albicans* (38.0%), *Candida* non-*albicans* (15.1%), *Aspergillus* spp. (7.3%), two or more *Candida* spp. (12.3%). Mean duration of treatment was 15 days at a mean dose of 3.7 mg/kg/day. In 47.5% of the cases L-AMB was used as rescue treatment after fluconazole (40 cases) or caspofungin (30 cases) and as first line in the other 52.5% of the cases. Clinical response in evaluable patients (n = 354) was classified as satisfactory in 53.9% (n = 33) of the cases (72.6% in proven infection) and microbiological eradication in evaluable patients (n = 308) was achieved in 67.6% (n = 33) of the cases. Adverse events were detected on 51 patients but were classified as serious in only 4 (2.2%) patients. Severe renal failure requiring a change in the antifungal treatment was detected in only one case. There was no change in the mean creatinine value at the end of treatment in the patients treated with L-AMB, despite the fact that 109 (60.9%) were receiving nephrotoxic drugs concomitantly.

Conclusions: L-AMB was used predominantly in critically ill patients (haemodynamically unstable), both as first line and as rescue treatment above all for proven infections. In this group of patients satisfactory clinical response was very high. L-AMB was well tolerated, with little alteration of renal function even in patients taking concomitant nephrotoxic drugs.

P1033 **Influence of liposomal amphotericin B on the renal function of intensive care patients with elevated serum creatinine levels. A multicentre, retrospective, observational case collection study**

F. Alvarez-Lerma, F. Mariscal, M. Nieto, M. Pérez, C. Pinilla, T. Puente, I. Ausín and the Study Group for Liposomal Amphotericin B in ICU

Objective: To study the influence of liposomal amphotericin B (L-AMB) on the renal function of intensive care patients with elevated serum creatinine levels (SCL) at the start of L-AMB treatment.

Methods: This is a sub-analysis of a pharmacoepidemiological retrospective study of patients admitted to Spanish intensive care units (ICUs) during 2006 and treated for at least one day with L-AMB. For this sub-analysis, only patients with SCL >1.5 mg/dl at the start of treatment (baseline) were included. Primary endpoint was SCL at the end of L-AMB treatment. Secondary endpoints were: discontinuation of treatment due to nephrotoxicity, and differences among groups (SCL ⩽1.5 mg/dl at the end of treatment vs SCL >1.5 mg/dl at the end of treatment) by dose and duration of L-AMB treatment, along with differences in the percentage of nephrotoxic concomitant drugs administered.

Results: Of the 179 patients admitted to the pharmacoepidemiological study, 49 (27.4%) presented with SCL >1.5 mg/dl (median: 2.3 and range: 1.53–7.0) at baseline. Of these 49 patients 83.7% were haemodynamically unstable, APACHE II score was 23.3 (SD: 8.8), mean length of ICU stay was 28.6 (SD: 24.0) days and intra-ICU mortality rate was 63.3%. Median dose of L-AMB was 3.6 mg/kg/day (range 1–6) and median duration of treatment was 12 days (range 1–33). Concomitant nephrotoxic drugs were taken by 59.2% (n = 39) of patients. At the end of L-AMB treatment, 40.8% (n = 30) of patients presented with SCL ⩽1.5 mg/dl, and the remaining 29 patients maintained SCL >1.5 mg/dl. Of this latter group, only seven patients presented with higher SCL than at baseline, none of them 1.5 x basal line value. No patient discontinued treatment due to nephrotoxicity. Comparing both groups of patients, no differences among dose of L-AMB and duration of treatment were seen. In addition, no differences were observed between groups in the percentages of patients taking nephrotoxic concomitant drugs.

Conclusion: Although this is a small case collection study, L-AMB was safely used in haemodynamically unstable patients with deteriorated renal function. No differences concerning dose and duration of L-AMB treatment, and concomitant nephrotoxic drugs were seen between both groups. L-AMB is a treatment option for high risk patients with deteriorated renal function.

P1034 Effectiveness and safety of AmBisome® (liposomal amphotericin B) in combination with voriconazole in patients with invasive fungal infections. A multicentre retrospective study (RAVES study)

E. Askari, P. García, I. Jarque, S. Nicolás, C. Blanco, M. Caballero, J. Cáceres, E. García, V. Gómez, M. Canales (Madrid, Valencia, Lorca, Palma de Mallorca, Las Palmas, Pamplona, ES)

Objectives: To study the efficacy and safety of the combination of AmBisome® and voriconazole in patients with invasive fungal infections (IFIs).
Methods: Retrospective, multicentre, data collection of patients treated with a combination of AmBisome® and voriconazole in Spanish hospitals. Data were included from patients treated for at least six days from October 2003 to November 2006. Infections were classified as proven, probable and possible according to the EORTC criteria. The primary endpoint was one month survival after drug study discontinuation.
Results: Thirteen patients were included in the study, eight were oncohematologic (five neutropenic) and five were intensive care patients. Four hematologic patients presented with a proven IFI (*Aspergillus flavus*, *Fusarium* spp., *Scedosporium* spp., and *Candida* spp.+unidentified mould), two with a probable IFI (*Fusarium oxysporum*, and Scesdosporium spp.) and two with a possible IFI (in one case cerebral toxoplasmosis was diagnosed in the necropsy study). Four intensive care patients presented with a proven infection (Candidaemia) and one patient showed a probable IFI (*Aspergillus flavus* and *Aspergillus fumigatus*). Doses of AmBisome® ranged from 2 to 5.5 mg/kg/day with a minimum treatment duration of six days and a maximum of 50 days. Two patients died within one month after study drug discontinuation: one patient after 48 hours and one after 30 days. Neither death was related to the fungal infection (one case cerebral toxoplasmosis and in the other one peritonitis). After discontinuation of study drug, a complete response was observed in nine patients, a partial response in three patients, and the patient with cerebral toxoplasmosis remained stable. Six patients experienced alterations in hepatic function, and in one of them voriconazole treatment was discontinued due to hepatotoxicity. No clinically relevant increases in serum creatinine levels (i.e. serum creatinine twice baseline level) were observed.
Conclusion: Although this is a small collection of cases, the efficacy results suggest no clinical antagonism of AmBisome® plus voriconazole in combination. Safety results suggest that this combination can be administered to high risk patients.

P1035 Safety of liposomal amphotericin as a once-weekly antifungal prophylactic regimen in very low birth-weight premature infants

A.C. Arrieta, K. Shea, V. Dhar, J. Cleary, S. Kukreja, N. Ashouri, J. Singh (Orange, US)

Objectives: *Candida* infections are a common cause of morbidity and mortality among very low birth weight (VLBW) infants. Several studies have shown that prophylaxis may decrease the incidence of candidiasis and improve survival. At a rate of 2.6/1000 patient days, a large number of infants will be exposed to drug to prevent one infection. The safety of a prophylactic drug then needs to be exhaustively evaluated. We studied the safety of liposomal amphotericin B (L-AmB) given once weekly at a 5 mg/kg dose as a prophylactic regimen to prevent *Candida* colonisation and invasive infection in VLBW < 6 weeks of age.
Methods: Premature newborns < 32 weeks gestation; <1500 g birth weight; < 7 days of life were eligible. Subjects were randomised to receive L-AmB 5 mg/kg once a week or placebo (dextrose in water). L-AmB trough level was obtained on day 7. Surveillance cultures were obtained at baseline, 72 hours later and then weekly from rectum, axillae and respiratory tract. Study drug was continued until no risk factors (antibiotics, central vascular access, hyperalimentation, endotracheal intubation) were present or 6 weeks of life which ever was earlier. Blood cultures were obtained as clinically indicated. Electrolytes, renal and liver function, as well as mortality and incidence of necrotising enterocolitis (NEC) and intraventricular haemorrhage (IVH) were monitored for safety.
Results: Twenty subjects were enrolled in to each study arm, demographic features and risk factors were evenly distributed. Steroids were used in 40% and 15% of L-AmB and placebo arms repectively. While on study, 5% on L-Amb and 15% on placebo arm developed colonisation; one subject on placebo developed invasive disease. One patient in each group died due to complications of prematurity. There was no significant difference in the incidence of IVH (grade III-IV), NEC or in the need for platelets, packed red blood cells and potasium supplementation. Renal and liver function changes were similar in both groups and of no clinical or statistical significance.
Conclusions: The safety of once weekly 5 mg/kg L-AmB in VLBW infants is supported by our trial and was comparable to placebo. Data from our pilot study suggests that a larger multi-centre trial is warranted

P1036 Comparison of antifungal therapy in intensive care unit and oncological patients

B. Luethi, J. Sasse, U. von Both, C. Ruef (Zurich, CH)

Objectives. New antifungal agents have enlarged treatment options for invasive fungal infections. However, these drugs are more expensive than older agents such as fluconazole (FLU) or amphotericin B (AmB). The purpose of this study is to describe antifungal therapy (AFT) in ICU and oncological patients at a European tertiary care hospital.
Methods: Prospective observational, non-interventional study on 3 ICUs and 1 oncology ward (ONC) to assess AFT, reasons for treatment changes and clinical outcome in 50 consecutive patients (48% female, median age 53.5, range 23–74 yrs; 36 ICU, 14 ONC). Standard criteria for the diagnosis of invasive fungal infections (IFI) were used.
Results: Mean length of hospitalisation was 59 days, the mean length of ICU stay 25 days. Overall mortality was 30%, without statistical difference between ICU and ONC patients. The following risk factors for IFI were highly prevalent: neutropenia (58%), use of broad-spectrum antibiotics (94%), total parenteral nutrition (18%), intraabdominal surgery (24%). We evaluated a total of 58 AFT cycles (1582 treatment days), including 103 courses (data for initial courses in table). Mean duration of treatment was 8.4 days (amB) 15.4 (CAS), and 14.7 (VOR). Modification of initial AFT was necessary in 50% of cycles. Rates of premature change (PC) of AFT for individual agents were: AmB (73.3% overall, 53.3% due to adverse events (AE)/20% due to treatment failure), FLU (31.3, 12.5/18.8), VOR (70, 50/20), CAS (28.6, 0/28.6). The rate of PC due to AE was significantly higher with AmB and VOR than with FLU and CAS.

	ONC [38 cycles; (% of cycles)]	ICU [20 cycles; (% of cycles)]
Indication for AFT		
Increased colonisation index	1 (2.6)	5 (25)
Fever and neutropenia[a]	20 (52.6)	3 (5)
Possible IFI[a]	12 (31.6)	1 (5)
Probable/proven IFI[a]	2 (5.3)	8 (40)
Physician's decision	3 (7.9)	3 (15)
Agent used		
AmB[a]	15 (39.5)	0
FLU[a]	5 (13.2)	14 (70)
Itraconazole (ITR)	2	0
Voriconazole (VOR)	7 (18.4)	3 (15)
Caspofungin (CAS)	7 (18.4)	3 (15)
Other	2	0

[a]Significant difference between ONC and ICU patients.

Conclusion: AFT in oncology is still predominantly based on AmB, which has been replaced in ICU patients by newer agents (VOR, CAS). In oncology patients indication for AFT is rarely based on probable or proven IFI, while this diagnosis is more often established in ICU pts. Premature discontinuation of AFT is frequent with AmB and VOR and is usually caused by AE.

P1037 Antifungal use in intensive care units

M. Èižman and the ESAC Study Group

Objectives: To provide benchmarking data on antifungal use in all intensive care units in Slovenian general hospitals and teaching hospital to analyse total use and general use pattern.
Methods: Antimicrobial use data for 21 ICU from all Slovenian general hospitals and one University hospital were obtained from January to December 2006 as part of the national antimicrobial consumption surveillance. Use data of systemic antifungals at the level of the active substance were collected in accordance with the Anatomic Therapeutic Chemical (ATC) classification and Defined Daily Dose (DDD) measurement unit (WHO version 2006) and expressed as DDD per 100 bed-days.
Results: During the year 2006 11 333 (2.95% of total number) patients were hospitalised in ICUs. The average length of stay was 3.99 days. Mean systemic antifungal use was 22.82 (range 0.87–67.52) DDD/100 bed-days; in medical ICUs (n = 3) 15.31 (range 2.86–46.56), in surgical (n = 3) 30.87 (0.87–67.52) in interdisciplinary (n = 3) 14.10 (7.72–23.0) and in University medical ICU (n = 3) 15.50 and in surgical ICU 42.21 DDD/100 bed-days respectively. Fluconazol was the most frequently prescribed antifungal (mean 21.0 DDD/100 bed-days) followed by caspofungin (0.62), amfotericin B (0.60), voriconazol (0.51) and itraconazol (0.05).
Conclusion: Antifungal use was heterogeneous in Slovenian ICUs with the mean lying at 22.82 DDD/100 bed-days. Benchmarking data might provide a tool for assessing strategies that aim to optimise antifungal prescribing in ICUs.

P1038 Disinfecting power of multi-purpose soft contact lens disinfecting solutions on fungi colonising the conjunctiva and environmental air isolates

C. Ma, M.V. Boost, P. Cho (Kowloon, HK)

Objectives: There has been increasing concern about fungal corneal infections since the outbreak of *Fusarium* infections in 2005 in soft contact lens wearers, which led to withdrawal of one multi-purpose disinfecting solution (MPS). Although FDA guidelines require MPS to reduce numbers of a type strain of *Fusarium solani* by one log dilution, their effectiveness on other strains is not routinely tested. Poor compliance with lens care routines and rubbing of the eyes can introduce fungi into the eye. This study investigated effectiveness of soft contact lens MPS against commensal and environmental fungal isolates.
Methods: The lower conjunctival surface and eyelashes of 30 subjects aged 20–24 were swabbed with a saline-moistened swab and cultured on potato dextrose agar with chloramphenicol (PDAc). Environmental fungi were obtained from ten cultures of PDAc exposed for 30 minutes in urban areas near to flower beds and lawns. Plates were incubated at 25°C for 7 days and fungal isolates sub-cultured, identified, and used as challenge strains against three soft lens MPS solutions using the stand-alone test required by FDA Guidelines. *F. solani* (ATCC 36031) was used as a control.
Results: Sixteen subjects were colonised with fungal organisms yielding a total of 23 isolates. Air sampling yielded a further 14 isolates. Isolates were mainly *Penicillium* (38%) and *Aspergillus* (30%) species, the latter being an ocular pathogen. Both MPS "A" and "B", which contain polyhexamethylene biguanide (PHMB), failed to achieve a one log reduction for any of the isolates though the reduction of *F. solani* was 1.3 log. MPS "C" which contains POLYQUAD was able to achieve a 1.0 or greater log reduction for all isolates.
Conclusions: MPS containing PHMB failed to successfully reduce viable fungal numbers by one log, although able to meet FDA Guidelines for the test strain of *F. solani*. Failure to inhibit such strains may increase the risk of ocular infection in contact lens wearers, as infections may be caused by other fungal pathogens, particularly *Aspergillus* spp. and poor compliance with lens care routines may lead to contamination with fungi. In the light of recent increase in microbial keratitis of fungal aetiology, changes to FDA guidelines to expand numbers of strains and species may be appropriate.

PK/PD: in vitro and animal studies

P1039 A daptomycin assay by high-performance liquid chromatography

C.M. Tobin, A.M. Lovering, A.P. MacGowan, J.M. Darville (Bristol, UK)

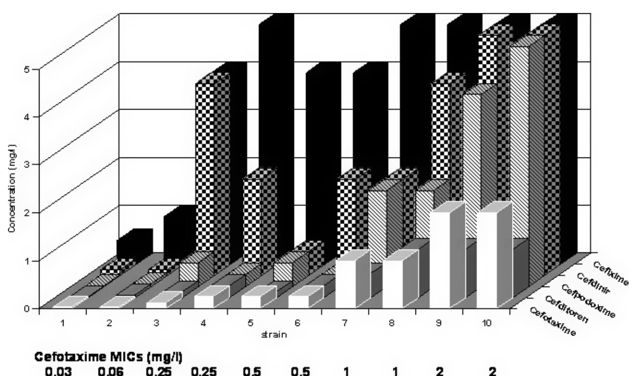
Objectives: Daptomycin (DAPT) is a new lipopeptide antibiotic with a unique mode of action. Its spectrum of activity includes most clinically relevant Gram-positive pathogens. With this drug there are few published pharmacokinetic data and these have been limited to healthy volunteers. With all new agents, it is important to be able to measure the serum concentrations, for an understanding of the drug's pharmacokinetics and for the management of patients with multiple organ failure. Our aim was to develop a high performance liquid chromatography (HPLC) method for therapeutic drug monitoring (TDM).
Methods: The column was a C-18, 5-micron (100 x 4.6 mm) with a guard column of the same material. The mobile phase was 0.2 M phosphate buffer, pH 5.5 and acetonitrile (70:30) and the flow rate, 1.5 mL/min. The samples were prepared by mixing with equal volumes of acetonitrile, left for 5 min and centrifuged (13,000g) for 5 min. Ten micro-litres of the supernatant was injected. DAPT was detected by UV absorbance (223 nm). The reproducibility, linearity, accuracy, precision, and the lowest limit of quantification (LLOQ) were investigated.
Results: The retention time (RT) was 6 min. The assay was reproducible: The % CV was 2.8 for a spiked serum containing 2.5 mg/L DAPT (n = 3). For a serum 5 mg/L DAPT sample, the intra-day assay precision %CV was < 4 (n = 32). The inter-day %CV was < 8. The assay was linear from 0.5 to 100 mg/L (R^2 = 0.9993). Serum recovery was > 93% when aqueous and serum samples 2.5, 20.0 and 100.0 mg/L were compared. The accuracy was excellent: the observed and the target concentrations (20, 40 & 80 mg/L) were closely correlated, with all the % errors <2.5. The LLOQ was 0.5 mg/L (n = 4, %CV was 5.2).
Conclusion: The HPLC method was reproducible, linear and accurate. It was straightforward and rapid with a RT of 6 min for DAPT and a total assay time of 10 min. It will be suitable for both a busy TDM laboratory and for the rapid processing of large batches of samples for research purposes.

P1040 Cidal activity of oral third generation cephalosporins against *Streptococcus pneumoniae* in relation to cefotaxime intrinsic activity

F. Cafini, L. Aguilar, L. Alou, M.J. Giménez, D. Sevillano, M. Torrico, N. González, J.J. Granizo, J.E. Martín-Herrero, J. Prieto (Madrid, ES)

Objective: To explore killing kinetics within 12 h of oral versus parenteral third generation cephalosporins against ten *S. pneumoniae* strains exhibiting cefotaxime MICs from 0.03 to 2 mg/l.
Methods: Killing curves were performed following CLSI recommendations with double dilution concentrations ranging from 0.015 mg/l to 4 mg/l (concentrations achievable in serum after standard doses) and a final inoculum of 1–2 10^6 cfu/ml. Colony counts were performed at 0, 2, 4, 6, 8, 10, 12 and 24 h. The killing kinetic profile of each antibiotic was defined as the figure resulting when concentrations needed to obtain 90%, 99% or 99.9% reductions in initial inocula within 12 h (dosing interval for oral cephalosporins) are plotted against strains distributed by increasing cefotaxime MICs.

Results: The Figure shows the concentrations needed to obtain 90% reduction in initial inocula within 12 h for the 10 study strains (white columns: cefotaxime; gray columns: cefditoren; diagonal stripes: cefpodoxime; black squares: cefdinir; black columns: cefixime).



Conclusion: The similarity of the killing kinetic profiles of cefditoren and cefotaxime may be important when choosing an oral third generation cephalosporin as initial or sequential therapy in areas with high penicillin resistance prevalence

P1041 Critical evaluations of generic piperacillin/tazobactam compared to the branded product: a worldwide sampling of 26 intravenous formulations

G. Moet, H. Sader, T. Fritsche, R. Jones (North Liberty, US)

Objective: To evaluate generic piperacillin/tazobactam (P/T) intravenous product activity by diffusion and MIC assays compared to branded product (Zosyn® or Tazocin®; Wyeth). P/T is a widely used penicillin/β-lactamase inhibitor combination (8:1 ratio). Recently, generic formulations have been introduced into various global markets said to possess bioequivalence and the original brand was reformulated using proprietary methods to enhance quality.

Methods: We studied "non-branded" generic lots for antimicrobial potency against 4 assay organisms (triplicate testing; P/T MICs, 1–4 mg/L), and directly compared to current branded agent. Generic P/T products (26 samples from 23 lots) were from Greece (3 lots), India (5), Philippines (10), Portugal (1), Taiwan (2), China (2), Jordan (1) and Spain (2). CLSI susceptibility testing applied reconstituted product sample vial contents to prepare panels having 20 dilution steps between 0.5–8 mg/L. Each strain was tested and the lowest reproducible MIC value was used for calculating lot potency compared to control (Zosyn® lot B75011).

Results: All tests were performed on the same day from fresh stock solutions. 4 manufacturers (Astral, Meditrina, YSS and Zurentus) had 2 or more lots. The branded formulation consistently produced the lowest MIC results (range, 1.0–3.5 mg/L) and generic products had MIC results that were consistently elevated, indicating reduced activity varying from –3 to –35% (ave. –16%; only Orchid Piptamate was equal). Largest differences were observed with Zopercin (151018; –21%), Tazidron (07077; –27%) and Vigocid (8001C; –35%), and the tazobactam effect also appeared diminished. A second sampling of 3 lots (PIPTAZ AUPM-601 and AUPI-601; Vigocid 8002C) exhibited consistently decreased activity that varied from –3 to –20%, demonstrating reproducibility of the MIC-based assay.

Conclusions: In vitro activities of various formulations of intravenous P/T products can vary significantly as assessed by this incremental MIC assay system when applying product vial content to reference dilution testing. Per-label activity was noted for the branded formulation and all but one generic lot (among 26 sampled from 15 manufacturers) had decreased potencies. Hospital formularies should be cautious when applying generic products without well-documented equivalence by chemical parameters, biologic tests related to in vivo bioavailability or clinical outcomes and direct in vitro potency assays.

Product (no. lots)	Assay organism MIC (mg/L)			% variation
	E. coli (2)	*P. aeruginosa*	*S. aureus*	
Zosyn control (1)	1.75–3.5	2.0	1.25	NA
STADA (2)	2.5–5.0	2.5–3.5	1.25–1.5	–15 to –23
Tazorex (1)	2.5–5.0	2.5	1.25	–23
Tazotum (2)	2.5–5.0	3.0	1.25–1.5	–11 to –16
Tazidron (2)	1.25–5.0	2.5	1.25	–13 to –27
Piptamate (1)	1.75–3.5	2.0	1.25	0

P1042 In vitro activity of tigecycline against *Stenotrophomonas maltophilia* tested by time-kill studies

B. Aracil, Y. Gil, J.L. Gómez-Garcés (Móstoles, ES)

Introduction: The pharmacodynamic activity of tigecycline for *Stenotrophomonas maltophilia* are not defined.

Methods: Antimicrobial susceptibility testing of 80 clinical isolates from 1996 to 2006 was performed by agar dilution. Tigecycline concentrations were serially increased in time-kill studies with representative strains of different susceptibility, MIC of 0.5 mg/liter, and MIC of 8 mg/liter. The in vitro susceptibility of the strains was tested by time-kill studies in duplicate. From an initial inocule gives of 0.5 105 ufc/ml serially counting were done at 0, 2, 4, 6, 24, and 48 h.

Results: Eighty isolates were tested and were found to have the following antimicrobial susceptibility profiles: tigecycline, MIC50 of 2 mg/liter and MIC90 of 4 mg/liter; ciprofloxacin, MIC50 of 1 mg/liter and MIC90 of 8 mg/liter; colistin, MIC50 of 16 mg/liter and MIC90 of 32 mg/liter; gentamycin, MIC50 of 16 mg/liter and MIC90 of 32 mg/liter; ceftazidime MIC50 of 32 mg/liter and MIC90 of 32 mg/liter; piperacillin-tazobactam MIC50 of 128 mg/liter and MIC90 of 128 mg/liter, and imipenem, MIC50 of 32 mg/liter and MIC90 of 32 mg/liter. According to FDA breakpoints 81.2% of the isolates were susceptible to tigecycline, 12% of the isolates were considered intermediate and 3 isolates were resistant. A reduction of 0, 0, 1, 2.2, 3, and 3 log10 was produced at 0, 2, 4, 6, 24, and 48 h., respectively.

Conclusion: Concentration escalation studies with tigecycline revealed a maximal killing effect near the MIC with no additional extent or rate of killing at concentrations 2× to 4× the MIC for tigecycline with independence of the categorisation were susceptible or resistant.

P1043 In vitro activity of tigecycline against *Acinetobacter baumannii* tested by time-kill studies

B. Aracil, Y. Gil, J.L. Gómez-Garcés (Móstoles, ES)

Introduction: Tygecicline is a new expanded broad spectrum antibiotic against *Acinetobacter baumannii*, its pharmacodynamic activity is not well defined yet.

Methods: Antimicrobial susceptibility testing of 85 clinical isolates from 1996 to 2006 was performed by agar dilution. Tigecycline concentrations were serially increased in time-kill studies with representative strains of different susceptibility: MICs of 0.5 mg/l, 1 mg/l., 2 mg/l, and 4 mg/l. The in vitro susceptibility of the strains was tested by time-kill studies in duplicate. From an initial inocule gives of 0.5 105 ufc/ml serially counting were done at 0, 2, 4, 6, 24, and 48 h.

Results: Eighty-five isolates were tested and were found to have the following antimicrobial susceptibility profiles: tigecycline, MIC50 of 0.25 mg/liter and MIC90 of 2 mg/liter; ciprofloxacin, MIC50 of ⩽0.25 mg/liter and MIC90 of 8 mg/liter; colistin, MIC50 of 1 mg/liter and MIC90 of 2 mg/liter; gentamycin, MIC50 of ⩽1 mg/liter and MIC90 of 32 mg/liter; ceftazidime MIC50 of 8 mg/liter and MIC90 of 32 mg/liter; piperacillin-tazobactam MIC50 of 32 mg/liter and MIC90 of 128 mg/liter, and imipenem, MIC50 of ⩽1 mg/liter and MIC90 of 32 mg/liter. According to FDA breakpoints 96.5% of the isolates were

susceptible to tigecycline. A reduction of 0, 0, 0, 1.2, 3.5, and 3.5 log10 was produced at 0, 2, 4, 6, 24, and 48 h., respectively.
Conclusion: Concentration escalation studies with tigecycline revealed a maximal killing effect near the MIC, with no additional extent or rate of killing at concentrations 2× to 4× the MIC for tigecycline for the susceptible and intermediate strains.

P1044 Bactericidal activity of simulated serum concentrations of daptomycin vs. vancomycin against vancomycin-susceptible and resistant *Enterococcus faecium*: a pharmacodynamic model

L. Alou, L. Aguilar, D. Sevillano, M.J. Giménez, M. Torrico, N. González, M.J. Estévez, J. Prieto (Madrid, ES)

Objective: To assess the influence of protein binding (36.9% for vancomycin – VAN – and 91.7% for daptomycin – DAP –) and the decreased susceptibility to VAN in *E. faecium* on the serum bactericidal activity of VAN and DAP over the dosing interval.
Methods: Serum concentrations after iv 6 mg/kg od DAP vs. 1000 mg bid VAN were simulated in an in vitro computerised one-compartment dynamic model using Mueller Hinton broth supplemented with 4g/dl human albumin and 100 mg/l calcium. Initial inocula: 7.0 log10 cfu/ml. Antibiotic concentrations and colony counts were determined (in triplicate) over 24 h. Pharmacokinetic parameters were determined and AUCall was calculated by the linear-log trapezoidal rule. *E. faecium* strains (S) were chosen based on VAN MIC/MBC (mg/l): S1(1/32); S2 (2/64) and S3 (128/>128), with DAP MIC/MBC values of 2/16, 2/8 and 4/16 mg/l, respectively.
Results: Cmax (mg/l), t1/2 (h) and AUCs (mg/l x h) were: 44.5 ± 2.6, 6.0 ± 0.5, and 286.5 ± 13.1 for VAN and 85.7 ± 5.8, 8.1 ± 0.2, and 852.7 ± 15.8 for DAP, respectively. Initial inocula ranged from 7.0 to 7.3 log10 cfu/ml. Mean ± SD colony counts (log10 cfu/ml) are shown in the table.

		4 h	6 h	12 h	24 h
VAN	S1	7.0±0.1	6.8±0.2	6.3±0.3	5.6±0.2
	S2	6.5±0.1	6.5±0.1	6.4±0.4	7.3±0.3
	S3	7.7±0.0	8.2±0.2	8.9±0.2	8.9±0.2
DAP	S1	4.7±0.6	4.0±0.6	2.6±0.4	3.8±0.7
	S2	5.1±0.1	4.9±0.1	4.5±0.1	4.0±0.6
	S3	4.7±0.0	4.0±0.2	3.1±0.5	3.6±0.3

Conclusions: DAP exhibited bactericidal activity (>=3 log10 reduction) at 24 h regardless VAN susceptibility, MBC values or presence of albumin physiological concentrations. VAN was not bactericidal (<1.5 log10 reduction) even against VAN-susceptible strains.

P1045 In vivo fluoroquinolone concentrations and in vitro selection of resistance in *Streptococcus pneumoniae*

E. De Vecchi, L. Nicola, S. Zanini, L. Drago (Milan, IT)

Objective: To compare the ability to select for resistance in *S. pneumoniae* of levofloxacin (LVX), ciprofloxacin (CIP), prulifloxacin (PRU) and moxifloxacin (MXF), which are commonly prescribed for treatment of community acquired infections in Italy.
Methods: Fluoroquinolones susceptible *S. pneumoniae* (n = 30) isolated from lower respiratory tract infections were used. Frequency of spontaneous single-step mutation allowing for bacterial growth in presence of plasma and epithelial lining fluid (ELF) peak and trough concentrations were calculated. Multistep selection of resistance was evaluated by performing 10 serial subcultures on antibiotic-containing agar plates, in which a linear gradient ranging from the peak to the trough concentrations of each drug was obtained, followed by 10 subcultures on antibiotic-free agar. LVX was tested at concentrations obtained with 500 mg and 750 mg dose. MICs were determined after 1, 5, 10 passages on antibiotic-gradient plates and after 10 subcultures on antibiotic free agar. Resistant strains selected after multistep selection were characterised for DNA mutations by sequencing gyrA, gyrB, parC and parE genes.
Results: LVX and MXF showed the lowest frequencies of mutations (median $<11^{-11}$) at plasma peak and at all ELF concentrations, while medians ranging from 10^-8 to 10^-6 were observed for CIP and PRU. In multi-step selection of resistance, CIP and PRU selected for the highest number of resistant strains (19 and 31, respectively. LVX selected for 2 resistant strains at plasma concentrations. No selection of resistance was observed for LVX ELF concentrations and for plasma and ELF MXF concentrations. Mutations in parC, parE and gyrA genes were found in CIP and PRU resistant strains, while only parC mutations were found for LVX.
Conclusions: LVX and MXF, which are known to possess the highest activity against *S. pneumoniae* among the tested fluoroquinolones, are also characterised by a lower capacity than CIP and PRU to in vitro select for resistance when tested at concentrations occurring in vivo.

P1046 In vitro selection of resistance by in vivo concentrations of fluoroquinolones in *Pseudomonas aeruginosa* and *Staphylococcus aureus*

L. Drago, L. Nicola, S. Zanini, E. De Vecchi (Milan, IT)

Objective: To compare the ability to select for resistance in *Staphylococcus aureus* and *Pseudomonas aeruginosa* of levofloxacin (LVX), ciprofloxacin (CIP), and prulifloxacin (PRU).
Method: Twenty strains of *S. aureus* and of *P. aeruginosa* susceptible to fluoroquinolones, isolated from lower respiratory tract, mainly of nosocomial origin, were considered. Frequency of spontaneous single-step mutation allowing for bacterial growth in presence of plasma and epithelial lining fluid (ELF) peak and trough concentrations were calculated. Multistep selection of resistance was evaluated by performing 10 serial subcultures on agar plates containing a linear gradient ranging from the peak to the trough concentration of each drug, followed by 10 subcultures on antibiotic-free agar. LVX was tested by considering concentrations obtained after 500 mg and 750 mg administration. MICs were determined after 1,5,10 passages on antibiotic-gradient plates and after 10 subcultures on antibiotic free agar.
Resistant strains selected were characterised for DNA mutations by sequencing gyrA, gyrB, grlA, parC and parE genes.
Results: Frequencies of mutations in *P. aeruginosa* were similar at plasma and ELF peak concentrations for LVX (median: 8×10^{-10} and $<10^{-11}$ at plasma, 4×10^{-11} and $<10^{-11}$ at ELF, LVX 500 mg and LVX 750 mg, respectively) and CIP (median: $<10^{-11}$ and 8.67×10^{-10}, at plasma and ELF, respectively) but higher for PRU (median: 1.25×10^{-8} and 1.01×10^{-7} at plasma and ELF, respectively). In *S. aureus* higher frequencies of mutations were obtained both with CIP (median: 1.11×10^{-7}) and PRU (median: 2.76×10^{-10}) than with LVX ($< 10^{-11}$) at plasma peak concentration.
P. aeruginosa was more prone than *S. aureus* in becoming resistant to fluoroquinolones after multi step selection (58 resistant strains vs 47, *P. aeruginosa* vs *S. aureus*). The lowest number of resistant strains was selected by LVX 750 mg both in *P. aeruginosa* (n = 33) and *S. aureus* (n = 3).
Mutations in gyrA, parC, grlA and gyrB were mostly associated with resistance.
Conclusions: Fluoroquinolones are characterised by a different ability to select for resistance, depending on bacterial species and in vivo drug concentrations. Generally, ELF concentrations selected for less resistant strains than plasma concentrations. Globally, LVX selected for less resistance than comparators both in *P. aeruginosa* and *S. aureus*.

P1047 Effects of β-lactams on mixed cultures of common respiratory isolates as an approach to treatment effects on nasopharyngeal carriage

D. Sevillano, L. Aguilar, L. Alou, M.J. Giménez, N. González, M. Torrico, F. Cafini, P. Coronel, J. Prieto (Madrid, ES)

Objectives: To explore β-lactam effects on the evolution over time of a bacterial load containing common pharyngeal isolates.
Methods: A computerised two-compartment pharmacodynamic model simulating free serum concentrations obtained with amoxicillin (AMX) 875 mg tid, amoxicillin/clavulanic acid (AMC) 875/125 mg tid and cefditoren (CDN) 400 mg bid regimens over 24 h was used. Strains and MICs (mg/l) of AMX, AMC and CDN were: *S. pyogenes* (0.03, 0.03 and 0.015), penicillin-resistant *S. pneumoniae* (PRP; 2, 2 and 0.25), a β-lactamase positive *H. influenzae* (BL+; >16, 2 and 0.06) and a β-lactamase positive AMC-resistant *H. influenzae* (BLPACR, >16, 8 and 0.06). A mixture of identical 1:1:1:1 volumes of bacterial suspensions of each strain were prepared yielding an inoculum approx. 4×10^6 cfu/ml. Antibiotic concentrations were measured both in bacteria-free antibiotic simulations (SBF) and in antibiotic simulations with the mixed inocula (SMI) and T>MIC calculated.
Results: T>MIC (% dosing interval) and mean % initial inocula reduction (%IIR; cfu/ml) are shown in the Table.

	CDN 400 mg bid			AMX 875 mg tid			AMC 875/125 mg tid		
	T>MIC		% IIR	T>MIC		% IIR	T>MIC		% IIR
	SBF	SMI		SBF	SMI		SBF	SMI	
S. pyogenes	84.3	79.0	E	99.9	24.9	92.8	99.9	99.9	E
PRP	24.0	25.6	94.1	43.2	17.7	41.8	40.8	32.8	78.4
BL+	57.4	58.0	E	0.0	0.0	+66.6	40.8	32.8	+20.1
BLPACR	57.4	58.0	E	0.0	0.0	+2.5	4.5	4.6	+215.1

E = eradicated (cfu/ml below limit of detection). Positive values mean regrowth.

β-lactamase production decreased AMX concentrations and T>MIC against PRP or *S. pyogenes*, and eradication was precluded. The presence of clavulanic acid countered this effect, and *S. pyogenes* was eradicated (but not BL+ and PRP). CDN resistance to TEM β-lactamase avoided this effect, and eradicated *S. pyogenes*, BL+ and BLPACR, and reduced in 94.1% *S. pneumoniae* counts.
Conclusions: Co-pathogenicity seems to be gradual since calvulanic acid countered this effect for strains very susceptible to AMX as *S. pyogenes* but not for strains with AMX MICs values in the limit of susceptibility as PRP. There is a potential therapeutic advantage for β-lactamase resistant cephalosporins with high intrinsic activity against streptococci.

P1048 Plasma protein binding of anidulafungin is similar to other major Echinocandins

P. Inskeep, J. Lin (Groton, US)

Introduction: Anidulafungin is one of three echinocandins approved in the USA for intravenous treatment of systemic fungal infections. Early reports, using ultracentrifugation methods relying on total radioactivity, indicated that protein binding of anidulafungin in human plasma (84%) was substantially lower than independently determined values of protein binding for caspofungin (97%) or micafungin (99%). Similar differences were observed for rat and dog plasma. Subsequent to the initial protein binding study with anidulafungin, a non-enzymatic intramolecular rearrangement of anidulafungin when incubated in plasma was observed. This product retains the radiolabel and thus would not be distinguishable from anidulafungin when total radioactivity is measured in the protein-free fraction from ultracentrifugation.
Objectives: To accurately determine protein binding at 37°C of unlabeled anidulafungin in rat, dog, monkey, and human plasma using dialysis and an LC/MS/MS method that is specific for parent.
Results: Using dialysis and the specific LC/MS/MS assay, greater than 99% of plasma anidulafungin was observed to bind to protein across the initial concentration range of 1.0 to 10 ug/mL for all 4 species (and 100 ug/mL in monkey plasma). Thus, all three major echinocandins appear to be extensively bound to plasma proteins. In addition, the amount of parent anidulafungin decreased during the incubation period suggesting that non-binding degradation products of anidulafungin were formed.
Conclusions: Plasma protein binding of anidulafungin is similar to other major echinocandins. These studies underscore the importance of using specific analytical methods, rather than total radioactivity, in assessing the protein binding of macromolecules having the potential for non-enzymatic rearrangements.

P1049 Lack of anidulafungin interactions with CYP enzymes and transporters in in vivo and in vitro systems

P. Inskeep, R. Walsky, B. Feng, S. Campbell (Groton, US)

Introduction: Anidulafungin (ANID) is one of three echinocandins approved in the USA for intravenous treatment of systemic fungal infections. Patients with severe fungal infections treated with echinocandins are usually hospitalised and on multiple drug regimens. The lack of drug-drug interactions (DDI) of and by ANID with other agents minimises the need for dose adjustments during polytherapy.
Objectives: Use in vivo and in vitro systems to assess the DDI potential of ANID.
Methods: Pooled human liver microsomes and purified CYP2C8 were used to investigate CYP interactions. In vivo studies in rats and monkeys were used to assess the potential for CYP induction. Transporter-transfected HEK cells were used to investigate the potential for ANID to interact with hepatic transporter systems.
Results: In pooled human liver microsomes, ANID did not inhibit CYP1A2, CYP2B6, CYP2C9, CYP2C19, CYP2D6 or CYP3A (IC50>17.5 uM), and a slight inhibition (12.0 uM) of CYP2C8 (amodiaquine N-deethylase activity) was observed. However, using purified recombinant human CYP2C8, no inhibition (IC50>17.5 uM) was observed (rosiglitazone N-demethylase activity). In a 4-week study in cynomolgus monkey dosed at 0, 2, 5, or 30 mg ANID/kg/day, no changes in total hepatic cytochrome P450 content were observed. In a 4-week study in Fischer 344 rats dosed at similar targeted doses, no increases occurred in hepatic enzymatic activity assessed by total P450 content, 7-ethoxyresorufin O-deethylase, benzphetamine N-demethylase (36% decrease in high dose male rats), and erythromycin N-demethylase activities. These studies demonstrate a low potential for ANID to induce hepatic enzyme activities. The potential for anidulafungin DDI via interaction with 3 major hepatic transporter systems was also investigated. ANID was not a substrate for organic anion transporting polypeptides hOATP-B, hOATP-C, and hOATP-8 across the concentration range of 0.01 to 100 uM. ANID did not inhibit uptake of probe substrates for hOATP-B or hOATP-C across the concentration range, and only showed slight inhibition of hOATP-8 (approx. 20%) at a concentration of 10 uM.
Conclusion: Given that circulating plasma concentrations of anidulafungin in humans at steady state following the 100 mg loading dose and 50 mg/day treatment are in the range of 1 to 3 uM, these results indicate a very low probability of DDI through CYP or OATP transporter interactions by anidulafungin.

P1050 The antibacterial activity of PZ-601 (SMP-601) against MRSA studied in an in vitro pharmacokinetic model

A. Noel, K. Bowker, A. MacGowan (Bristol, UK)

Objectives: PZ-601 (PZ) is a new injectable carbapenem with in vitro activity against MRSA ⩽2 mg/L. We studied the antibacterial activity of PZ at simulated human serum concentrations against 5 strains of MRSA, PZ MIC range 0.09–2 mg/L, in an in vitro pharmacokinetic (pK) model.
Methods: A single compartment open dilutional in vitro pK model was used. 5 strains of MRSA were tested: representative strains of UKEMRSA 15 (PZ MIC 0.38 mg/L), UKEMRSA 16 (PZ MIC 0.19 mg/L), the Michigan strain VISA (PZ 0.75 mg/L) and two MRSA

with MIC values on the low (PZ MIC 0.09 mg/L) and high (PZ MIC 2 mg/L) ends of the MIC distribution. PZ concentrations simulated were Cmax of 35 mg/L, $t_{\frac{1}{2}}$ 1.5 h with dosing 12hly for 48 h. The inoculum was 10^6 CFU/ml. Emergence of resistance was assessed by population analysis profiles.
Results: The antibacterial effect was – PZ reduced MRSA count by 2.3–4.3 logs at 24 h and >4 logs at 48 h. Strain kill kinetics were similar across the range of MICs tested. No resistance was detected.
Conclusion: PZ-601 at simulated human serum concentrations had a marked antibacterial effect against MRSA strains MIC ⩽2 mg/L

	Strain

P1051 The antibacterial activity of telavancin and vancomycin against UK EMRSA 15 and 16 strains studied in an in vitro pharmacokinetic model

A. Noel, K. Bowker, S. Tomaselli, A. MacGowan (Bristol, UK)

Objective: Telavancin (tela) is an injectable new semi synthetic lipoglycopeptide antibiotic with broad activity against Gram-positive pathogens including MRSA. It has a double mechanism of action on the cell membrane and wall resulting in bactericidal activity. We used an in vitro pharmacokinetic (pK) model to simulate serum free drug concentrations of tela and vancomycin (vanco), and studied their antibacterial effect against representative strains of UK EMRSA 15 and 16.
Methods: A single chamber dilutional in vitro pK model was used to simulate serum free drug concentrations. Tela Cmax 10 mg/L, $t_{\frac{1}{2}}$ 8 hr, 2 doses over 48 h; vanco Cmax 14 mg/L, Cmin 3.5 mg/L, 4 doses over 48 h. Two strains of UK EMRSA 15 and 16 were used (both tela MIC 0.19 mg/L). Experiments were performed in triplicate at an initial inoculum of 10^6 CFU/ml. Antibacterial effect was measured by log change in viable count at 6 h (d6), 12 h (d12), 24 h (d24) and 48 h (d48). The maximum kill was recorded (dmax) and the area-under-the-bacterial-kill curve between 0–24 h (AUBKC24) and 0–48 h (AUBKC48) calculated.
Results: The killing kinetics of both strains were similar, therefore the antibacterial effect measures were pooled for tela and vanco, and compared.
Conclusion: Tela produced significantly greater early killing of EMRSA 15 and 16 than vancomycin (d6, d12). The maximum kill was also greater (dmax) as was the antibacterial effect in the first 24 h (AUBKC24).

P1052 Inoculum effect of β-lactams and killing curves determination in AmpC-producing (DHA-1) *Klebsiella pneumoniae* isolates

H. Cerna, T. Bergerova, P. Urbaskova, J. Hrabak (Plzen, Prague, CZ)

Objectives: An inoculum size is a critical point in treatment of infections caused by extended-spectrum β-lactamase- and AmpC-producing bacteria. A treatment failure was described in many cases of infections due to these bacteria. An inoculum effect determined by standard dilution method is not an appropriate model of the infection process in organism. The aim of this study is to compare the inoculum effect determination on β-lactams by a standard microdilution method and the description of dynamic of bacterial population of AmpC-producing *Klebsiella pneumoniae* after addition these antibiotics.
Methods: Four DHA-1 producing *Klebsiella pneumoniae* strains (two inducible and two with high level of expression) were used in this study. MIC and inoculum effect was determined by a classical microdilution broth method (CLSI). Dynamic of bacterial population – bacterial count was measured by direct plating samples after addition antibiotic in brain-heart infusion.
Results: Using standard inoculum (10^5 CFU per ml), the strains producing inducible AmpC were determined as non-resistant to cefotaxime (CTX) (MIC = 1 mg/l), ceftazidime (CAZ) (MIC = 4 mg/ml) and cefepime (FEP) (MIC = 2 mg/l) according to EUCAST criteria. When the inoculum was 10^6 CFU/ml, the strains were resistant to all tested β-lactams (e.g. MIC of CTX was 256 mg/ml, MICs of CAZ and FEP were 1024 mg/ml). The strain with a high-level expressed AmpC was not resistant only to cefepime (MIC = 2 mg/l). MIC of CTX was 64 mg/l and of CAZ 128 mg/l. Killing curves showed different times required for an inactivation of antibiotics. For the strains producing inducible AmpC, decreasing count of bacteria were observed in CTX for 6 hrs in a concentration of 1 mg/l, at least for 7 hrs in a concentration of 2 mg/l, in CAZ for 3 hrs in a concentration of 1 mg/ml, for 6 hrs in a concentration of 8 mg/l and in FEP for 3 hrs in a concentration of 1 mg/l and at least for 7 hrs in a concentration of 8 mg/l.
Conclusions: This work showed that the time required for hydrolyzing antibiotics by β-lactamases under the MIC is shorter than the time recommended for MIC reading by standard method. Therefore the data obtained using microdilution method do not exactly described the situation in the organism and the inoculum effect could be misinterpreted due to lack of antibiotic in a well of microtiter plate.
This work was supported by a research project MSM 0021620819.

P1053 In vitro enrichment of resistant *Staphylococcus aureus* at daptomycin subtherapeutic concentrations within the mutant selection window: effect of treatment duration

S. Vostrov, I. Lubenko, S. Zinner, A. Firsov (Moscow, RU; Cambridge, US)

Objective: To study time-dependent enrichment of resistant sub-populations and concomitant loss in susceptibility of *S. aureus*, ten-day treatments with daptomycin (DAP) were simulated in vitro.
Methods: *S. aureus* ATCC 43300 (MICDAP 0.2 mg/L) was exposed to once-daily dosing of DAP at subtherapeutic ratios of area under the curve (AUC) to the MIC of 32 and 64 h, which have been reported recently to result in maximal selection of resistant mutants. Susceptibility (culture MIC) and bacterial growth on agar plates containing 2× and 4×MIC were tested daily. To provide an integral presentation of the time course of mutants grown on DAP-containing plates, areas under the bacterial mutant kinetic curves (AUBMCs) were calculated from the start of treatment to the 3rd (AUBMC3), 5th (AUBMC5) and 10th day (AUBMC10) of treatment.
Results: With both dosing regimens, DAP-resistant *S. aureus* were enriched on the third day. Further enrichment occurred gradually, without abrupt increases in mutant numbers. By the end of each treatment, numbers of mutants resistant to 2× and 4×MIC of DAP were comparable to those of susceptible organisms, but they were not completely replaced

by DAP-resistant mutants. Similar patterns were inherent in the time course of susceptibility of DAP-exposed cultures, with 16- and 8-fold increases in the MIC by the end of treatment at AUC/MIC of 32 and 64 h, respectively. This gradual enrichment of resistant mutants and concomitant loss in susceptibility were confirmed by the AUBMC analysis. At AUC/MIC of 32 h, production of mutants resistant to 4×MIC was reflected by a 2.9 times greater AUBMC10 than AUBMC5 and by a 2.2 times greater AUBMC5 than AUBMC3. At AUC/MIC of 64 h, AUBMC10 was 3 times greater than AUBMC5 and AUBMC5 was 2.1 times greater than AUBMC3.

Conclusions: The time-resistance relationships established in this study: (1) allow prediction of subsequent enrichment of DAP-resistant mutants and concomitant loss in susceptibility after long-term treatments based on data obtained in shorter treatments, and (2) show that relatively minimal early expressions of resistance seen in short treatments are precursors of more resistance that occurs with longer DAP treatments.

P1054 Daptomycin pharmacodynamics against *Staphylococcus aureus* hemB mutants expressing the small colony variant phenotype

D. Begic, C. von Eiff, B. Tsuji (Buffalo, US; Münster, DE)

Objectives: *S. aureus* small colony variants (SCVs) are slow-growing morphological variants of *S. aureus* that have been associated with poor clinical response to prolonged antimicrobial therapy. Recently, we determined that vancomycin bactericidal activity is attenuated against genetically defined *S. aureus* mutants displaying the SCV phenotype. Limited data exist on the killing activity of daptomycin (DAP) against SCVs. In this study, the bactericidal activity & pharmacodynamics (PD) of DAP were evaluated against site-directed hemB mutants (hemB::ermB) displaying the SCV phenotype.

Methods: The wild-type meticillin-resistant *S. aureus* strain COL & the meticillin-susceptible strain Newman, as well as their corresponding hemB mutants with SCV phenotype, Ia48 & III33, were used for these studies. MICs were performed in quadruplicate as per CLSI. Log phase time kill experiments were performed in duplicate for each strain at 10^6 CFU/ml at increasing DAP concentrations (0, 0.5, 1, 2, 4, 8, 16, 32, 64 times the MIC) over 24 h. PD analysis was performed using an integrated area approach for reduction in area under the CFU versus time curve from 0 to 24 h, Log10(AUCdrug/AUCgrowth control) versus DAP concentration:MIC which was fit to a Hill-type pharmacodynamic model.

Results: MICs for DAP against COL, Newman, Ia48, and III33 were 1.0, 1.0, 2.0 & 2.0 mg/L, respectively. DAP exhibited concentration dependent, bactericidal activity against both *S. aureus* phenotypes. Against the wild type strains COL and Newman exposure to DAP at concentrations ⩾4.0 x MIC achieved 99.9% kill by 6 h. Values >4.0 log10 CFU/ml reductions occurred at 4 h exposed to ⩾8.0 x MIC of DAP. Against both mutants, 99.9% kill was achieved for DAP ⩾16 x MIC in ⩽8 h. Maximal bacterial reductions for normal phenotype/hemB mutant COL/Ia448 & Newman/III33 at 24 h at maximal exposure were –5.4/–5.0 –5.5/5.0 log10 CFU/ml. Maximum likelihood parameter estimates for reduction in area for Emax for COL/Ia48 & Newman/III33 were 5.8/4.6 & 5.6/4.5. PD model fits describing the concentration-effect relationship for DAP vs. all strains were excellent ($r^2 \geqslant 0.97$).

Conclusion: *S. aureus* SCVs represent a major therapeutic challenge. DAP achieved rapid and sustained bactericidal activity against both *S. aureus* hemB mutants tested displaying the SCV phenotype. This study may have implications for the optimal therapy of persistent and difficult-to-treat infections due to *S. aureus* SCVs.

P1055 In vitro adsorption and release of antibiotics from cancellous bone

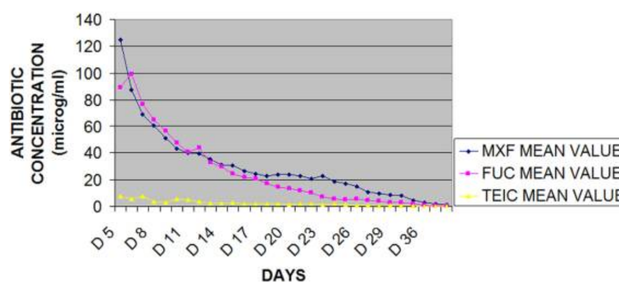
T. Sahinides, K. Kanellakopoulou, N. Galanakis, Z. Chrisouli, H. Giamarellou (Athens, GR)

Objectives: Drug delivery systems have become of significant importance in the contemporary management of chronic bone infections. Several antibiotics have been studied for their release patterns from cancellous bone. We report the adsorption and elution profile of human cancellous bone impregnated with moxifloxacin (MXF), teicoplanin (TEIC) and fucidic acid (FUC).

Methods: ~1 g of processed cancellous bone was compressed into a wire-mesh cylinder made of stainless steel and impregnated with 5 ml of antibiotic solution (100 mg/ml, active product ingredient) for 1 hour at room temperature. Five replicates for each antibiotic were incubated separately at 37 oC in 5 ml of Mueller Hinton broth and transferred daily into a new elution tube for 42 days. The amount of antibiotic eluted in broth was assessed by a microbiological assay (agar diffusion using *Bacillus subtilis* ATCC 6633 for MXF and TEIC and *Corynebacterium* 404 CIP 5216 for FUC).

Results: High concentrations of MXF and FUC were measured on the first 5 days (>100 μg/ml) with a rapid decline until day 10 (mean value ~50 μg/ml), showing a steady state curve thereafter. On day 20 the MXF concentration remained significant (~25 μg/ml), whereas the amount of FUC decreased to ~13 μg/ml. On day 30 MXF concentration maintained a value of ~10 μg/ml as opposed to FUC concentration (~2.9 μg/ml). By day 40 the MXF level was reduced to ~2 μg/ml. On the contrary, very low levels of TEIC were measured after the first 4 days (<10 μg/ml).

Conclusion: After an initial burst of release in the first 5 days, MXF attained high concentration in the elution fluid for up to 4 weeks. FUC had a similar release pattern reaching the lowest values in less time. TEIC was found to have an inferior elution profile against the other two antibiotics. Cancellous bone can be used as a carrier of antibiotics for local delivery. The implications of these findings need to be examined in the clinical setting.



Antibiotic elution profile.

P1056 Hypoxia induces antibiotic resistance in *Pseudomonas aeruginosa*

B. Schaible, K. Schaffer, D. Keating (Dublin, IE)

Objectives: Cystic Fibrosis (CF) is an autosomal recessive disorder with a frequency in Ireland of 1/1461 live births. Pulmonary *Pseudomonas aeruginosa* infection contributes significantly to morbidity and mortality in CF. Within the CF lung biofilm *P. aeruginosa* is exposed to hypoxic conditions and is often found to be multiresistant to various antibiotics. In this study we investigated the influence of hypoxia on antibiotic resistance in *P. aeruginosa*.

Methods: *P. aeruginosa* was incubated in cation adjusted Mueller-Hinton broth for 6 h under either ambient normoxic (21% oxygen) or hypoxic conditions (1% oxygen). IC50 values for chloramphenicol, ciprofloxacin hydrochloride, novobiocin, tetracycline and tobramycin were determined after incubation of *P. aeruginosa* in increasing antibiotic concentrations in either normoxia or hypoxia. IC50 values were calculated as changes in optical density measurements (OD610). To identify potential molecular mechanisms underlying resistance development, expression levels of the 4 major multidrug efflux pumps of *P. aeruginosa* (mexAB-OprM, mexCD-OprJ, mexEF-OprN) were investigated. After incubation in hypoxia bacterial mRNA was isolated using phenol chloroform extraction and reverse transcribed. Expression levels were measured by real time PCR with primers amplifying segments from mexA, mexC, mexE cDNA.

Results: Incubation in hypoxia for 6 h significantiy increases IC50 values for ciprofloxacin HCl (p = 0.038) and tobramycin (p = 0.006). IC50 values for chloramphenicol (p = 0.076) and novobiocin (p = 0.083) were increased without reaching significance. Hypoxia did not affect IC50 values for tetracycline. Preliminary analysis of mRNA expression levels for mexA, mexC and mexE showed no difference between normoxic and hypoxic conditions.
Conclusion: Short term incubation in hypoxia increases antibiotic resistance in *P. aeruginosa*. We speculate that hypoxia within the CF lung could be an important stimulus for the development of antibiotic resistance.

P1057 Evaluation of vancomycin and daptomycin against MRSA and hVISA in an in vitro PKPD model with simulated endocardial vegetations

M. Rybak, S. Leonard (Detroit, US)

Objectives: Historically vancomycin (VAN) has been the primary treatment for infections caused by meticillin-resistant *Staphylococcus aureus* (MRSA). However, continued selective pressure has led to non-susceptible strains including hVISA. Infections with hVISA are associated with prolonged bacteraemia and VAN failure and are often high bacterial load infections. Our own study of hVISA at the Detroit Medical Center (DMC) from 2003–2006 demonstrated a prevalence of 8.3%. The objective of this study is to evaluate VAN and daptomycin (DAP) against VAN susceptible MRSA and hVISA in a PK/PD simulated endocardial vegetations (SEV) model.
Methods: Five clinical isolates were used, MRSA 494, MRSA 67, hVISA(s) 1720, 2295 and 1629. All isolates were obtained from the DMC. The hVISA strains were confirmed by population analysis profile ratio with Mu3 as the control strain. Simulated doses of VAN 1 g Q12 h (Cmin 5–10 mg/L) and 2 g Q12 h (Cmin 15–20 mg/L), and DAP 6 mg/kg Q24 h (Cmax 95.7 mg/L), 10 mg/kg Q24 h (Cmax 129.7 mg/L), and 12 mg/kg Q24 h (Cmax 164.8 mg/L) were used in the PK/PD SEV model over 72 h in duplicate. Changes in bacterial CFU/g at 72 h were compared by ANOVA with Tukey's post-hoc test. $P \leqslant 0.05$ was considered significant.
Results: VAN MIC was 0.5 mg/L for MRSA 494, MRSA 67, and hVISA 1720; 1 mg/L for 2295; and 2 mg/L for 1629. DAP MIC values were 0.125 for MRSA 67 and hVISA 1720 and 0.25 mg/L for MRSA 494, hVISA 1629, and hVISA 2295. Against both MRSA strains DAP 10 and 12 mg/kg killed to detection limits (> 7 log10 CFU) by 24 h and 6 mg/kg by 48 and 56 hours (average T99.9 for 6 mg/kg – 6.2 h; 10 mg/kg – 2.7 h; 12 mg/kg – 2.4 h) whereas VAN achieved a maximum kill of 2–3 log10 CFU/g by 72 h (P<0.01). Against hVISA strains, VAN only reduced the bacterial load by 1–1.5 log10 CFU/g over 72 h regardless of dose exposure, whereas DAP achieved rapid bactericidal kill (average T99.9 for 6 mg/kg – 10 h; 10 mg/kg – 5.6 h; 12 mg/kg – 4.8 h) to detection limits of 2 log10 CFU/g (P< 0.01).
Conclusion: Overall, DAP achieved rapid and effective kill against both MRSA and hVISA. VAN however, displayed slow and minimum kill against MRSA at high inoculum and displayed minimal to no activity versus hVISA regardless of high dose exposure. Further evaluation of high-dose DAP is warranted.

P1058 Intracellular activity of antibiotics against a stable small colony variant of *Staphylococcus aureus* isolated from a CF patient in model Calu-3 human airway epithelial cells

H.A. Nguyen, O. Denis, A. Vergison, P.M. Tulkens, M.J. Struelens, F. Van Bambeke (Brussels, BE)

Objectives: Persistence of *S. aureus* infections in CF may be related to the presence of small colony variant (SCV) variants and of intracellular bacteria. Using a stable thymidine-auxotrophic mecA negative SCV of *S. aureus* isolated from a CF patient, we showed that most antibiotics (AB) act only poorly on intracellular forms in a model of human THP-1 macrophages (ICAAC 2007, abstr. A1437). We have now compared the activity of commonly used (gentamicin, rifampicin, vancomycin, moxifloxacin) and newly developed AB (linezolid, tigecycline, oritavancin) against this SCV isolate using Calu-3 cells as a model of airway epithelium.
Methods: MICs were determined in MH broth after 48 h incubation. Intracellular activities (IA) were measured as the change in post-phagocytosis inoculum [delta log CFU] after 24 h or 96 h in Calu-3 cells (normal bronchial epithelial cells) incubated with ABs at extracellular concentrations (Ce) corresponding to their respective peak (Cmax), free peak (fCmax), trough (Cmin) and free trough (fCmin) in plasma when administered at standard doses.
Results: Over 24 h, the intracellular inoculum remained constant (–0.14 ± 0.01 log CFU with 10 mg/L lysostaphin to prevent extracellular growth). All AB showed a concentration-dependent effect, with a significant inoculum decrease at Cmax for TGC, LNZ and RIF, fCmax for MXF, Cmin for ORI low dose, and fCmin for GEN, VAN and ORI high dose. At 96 h, the activity of all drugs (except LNZ and TGC) markedly progressed at Cmax, approaching or reaching a bactericidal effect, while regrowth was observed at Cmin for all drugs but VAN, MXF and RIF.

AB	MIC (mg/L)	delta log CFU measured at 24 h for Ce (mg/L) corresponding to							
		Cmax		fCmax		Cmin		fCmin	
		Ce	IA	Ce	IA	Ce	IA	Ce	IA
TGC	0.125	1	–0.54±0.05	0.2	0.17±0.04	0.13	0.18±0.12	0.026	0.55±0.14
LNZ	2	16	–0.98±0.07	8	–0.19±0.04	4	–0.16±0.08	2	0.21±0.09
RIF	0.0005	18	–0.59±0.08	2.7	–0.28±0.08	1.2	–0.23±0.11	0.18	–0.14±0.09
MXF	0.125	4	–1.74±0.18	2	–1.34±0.05	0.4	–0.20±0.08	0.2	0.17±0.02
GEN	0.125	18	–1.72±0.10	18	–1.72±0.10	1.5	–0.62±0.11	1.5	–0.62±0.11
VAN	0.5	50	–1.59±0.01	22.5	–1.28±0.04	10	–0.93±0.12	4.5	–0.89±0.09
ORI 200 mg	0.015[a]	32	–1.91±0.02	4	–1.27±0.05	2	–0.85±0.05	0.5	–0.22±0.02
ORI 800 mg	0.015[a]	128	–2.53±0.53	16	–1.61±0.05	16	–1.81±0.05	2	–0.85±0.05

[a] In the presence of 0–0.002% P80.

Conclusion: Prolonged incubation with high concentrations of bactericidal drugs is needed to durably act on intracellular SCVs, suggesting the importance of AB selection and PK/PD optimisation to avoid failure in eradicating these bacteria in CF patients.

P1059 Activity of antibiotic combinations towards intracellular small colony variants of *Staphylococcus aureus* in a model of THP-1 macrophages

H.A. Nguyen, O. Denis, A. Vergison, P.M. Tulkens, M.J. Struelens, F. Van Bambeke (Brussels, BE)

Objectives: In a model of human THP-1 macrophages intracellular infection, small colony variants (SCV)s of *S. aureus* have been shown to be poorly susceptible to most antibiotics (ICAAC 2007, A1437), except ORI, MXF or RIF (–2 log CFU in 24 or 72 h). In the present study, we have examined whether combining these drugs could further enhance intracellular efficacy in comparison with conventional associations (RIF-OXA, RIF-VAN, RIF-FA) as comparators.
Methods: We used a stable thymidine-auxotrophic mecA negative SCV of *S. aureus* isolated from a cystic fibrosis (CF) patient. MICs were determined in MH broth after 48 h incubation. Intracellular activities were measured as the change in post-phagocytosis inoculum [delta log CFU] after 24 h or 72 h of incubation with antibiotics at extracellular concentrations corresponding to their respective serum peak concentration (Cmax) when administered at standard doses.
Results: Combination of RIF with OXA, VAN, FA, or MXF was indifferent (same activity as RIF alone at 24 h, slight reduction at 72 h). In contrast, combination of ORI with RIF or MXF resulted in synergistic effects both at 24 h and 72 h (higher activity than observed for the most active drug given alone), with RIF-ORI reaching the limit of detection at 72 h.
Conclusion: The data suggest that combining oritavancin with other bactericidal antibiotics may prove useful for eradicating intracellular SCVs, and plead for the further evaluation of such combinations in in vivo pertinent models of recurrent staphylococcal infections that imply SCVs.

P1060 Identification of a *Staphylococcus aureus* strain with increased intracellular growth and reduced intracellular susceptibility to gentamicin

A. Olivier, F. Van Bambeke, M.P. Mingeot-Leclercq, P.M. Tulkens (Brussels, BE)

Objectives: The persistence and recurrence of many *S. aureus* infections (such as endocarditis) has been ascribed to its intracellular character. Our aim was to examine the intracellular development of *S. aureus* strains differing by their hemolysin (hl) production as well as their intracellular response to antibiotics, using both phagocytic (THP-1) and endothelial cells (HUVEC).
Methods: Intracellular growth was measured by the change in CFU (Delta log /mg prot.) recorded 24 h after infection. Controls were maintained with gentamicin (1 x MIC) to prevent the development of extracellular bacteria. Confocal microscopy was performed with bacteria tagged with fluorescein isothiocyanate, and vital staining of lysosomes using LysoTracker® Red DND 99.

Strain	Characteristics	Gentamicin MIC[a] (μg/mL)	Intracellular growth in THP-1	Gentamicin concentr. (in × MIC) allowing to reach a static effect	
				Intracell.	Extracell.
8325-4	Laboratory strain cured of all prophages.	0.2	0.2±0.1	2.3 × MIC	1.5 × MIC
DU5942	Mutant derived from 8325-4. Disrupted for gamma-hemolysin (hlg)	0.3	1.9±0.1*	5.0 × MIC	1.3 × MIC
DU5942-M1	Mutant derived from 8325-4. Disrupted for hlg and complemented with pCU1-*hlg+*	0.3	1.8±0.1*	5.0 × MIC	1.3 × MIC
DU5938	Mutant derived from 8325-4. Disrupted for alpha- (hla), beta- (hlb), and gamma- (hlg) hemolysins	0.2	0.3±0.1	–	–

n = 3. *p < 0.001 (ANOVA)
[a]Microdilution in Mueller-Hinton broth pH 7.4.

Results: *S. aureus* DU5942 showed a more important intracellular growth than the other strains (also observed in HUVEC). This was not due to hlg disruption, since it was also observed for the complemented strain DU5942-M1 but not for the multidisruptant strain DU5938. Dose-effects studies with gentamicin showed a similar response for all tested strains extracellularly. In contrast, DU5942 and its M1 mutant were less sensitive to gentamicin than 8325–4 intracellularly, exposure to higher extracellular concentrations being required to prevent intracellular growth. No difference was seen between strains for other antibiotics (oxacillin, vancomycin or telavancin). Confocal microscopy showed that, after 24 h of infection, all strains were confined in lysosomes in THP-1 macrophages. In endothelial cells, most bacteria colocalised with lysosomes but a small number appeared free in the cytoplasm.
Conclusion: We identified a strain with high capacity of intracellular growth in both professional phagocytes and endothelial cells. This effect seems to be related to a lower intracellular susceptibility of the strain to gentamicin but not to its hl status.

P1061 Quantitative determination and pharmacokinetics of oritavancin in rabbit serum and tibia

O. Bélanger, O. Rozborskaya, E. Dietrich, M. Malouin, V. Ostiguy, I. Fadhil, K. Laquerre, D. Lehoux, A. Rafai Far, T.R. Parr Jr. (St-Laurent, CA)

Objectives: Oritavancin is a novel lipoglycopeptide characterised by its activity against Gram-positive organisms, including vancomycin-resistant staphylococci and enterococci, and its long half-life. It is under preclinical evaluation for the treatment of osteomyelitis, an acute or chronic bone infection predominantly caused by staphylococci and requiring prolonged parenteral antibiotic administration. Given the importance of the rabbit model of chronic osteomyelitis in predicting clinical efficacy, we report here pharmacokinetic parameters in rabbit serum and tibia.
Methods: Rabbits were administered a single intravenous (IV) dose of oritavancin at 20 mg/kg. They were sacrificed at 7 time points ranging from 5 minutes to 7 days (n = 3/time point), a blood sample was collected and the tibiae were harvested and ground to a powder. Oritavancin was extracted from serum by the precipitation of serum proteins with acidified acetonitrile. Given the difficulties in extracting the oritavancin from bone, an indirect method of analysis was sought whereby the concentration of oritavancin was determined through the detection of a product of acidic degradation, 4-(4-chlorophyl)benzyl-4-epi-vancosamine (CBV). A 50 mg fraction of the tibia powder was acidified with 0.5 ml of 1N HCl and incubated for 5 minutes at 70 degrees Celsius. After centrifugation, the supernatant was transferred and the pellet treated two times under the same conditions. CBV in the pooled supernatants was concentrated by solid phase extraction. The quantitative determinations of oritavancin and CBV relied on liquid chromatography/mass spectrometry (LC/MS).
Results: The dose-response curves of oritavancin in serum and in tibia were linear with a limit of quantitation (LOQ) of 0.0125 mg/L and 0.2 mg/kg, respectively. The serum concentration was 200 mg/L at 5 minutes with a half-life of 2.4 hours, falling below 5 mg/L after 24 hours with a terminal half-life of 40 hours. The maximal concentration of the drug in tibia was 15 mg/kg of bone, reached at 5 minutes and maintained for at least the first 24 hours, and a half-life of 12 days. The calculated area under the curve (AUC) in serum and tibia was 1001 hour x mg/L and 1992 hour x mg/kg, respectively.
Conclusion: Oritavancin rapidly penetrates in osseous tissues and is maintained there at high concentration. It is slowly eliminated, such that its levels are maintained for days, suggesting a potential for the treatment of bone infection.

P1062 In vivo selection of carbapenem-resistant *Pseudomonas aeruginosa* following sub-optimal dosing

V.H. Tam, K.R. Ledesma, A.N. Schilling, K.T. Chang, T.P. Lim, R. Ghose, R.E. Lewis (Houston, US; Singapore, SG)

Objective: We have previously demonstrated *P. aeruginosa* (PA) resistance emergence due to sub-optimal carbapenem exposures in an in-vitro infection model (Antimicrob Agent Chemother 05), but the in-vivo relevance of the observations is not well established. We examined the impact of a sub-optimal carbapenem exposure on PA resistance emergence in a neutropenic murine pneumonia model.
Methods: Female Swiss-Webster mice (22–26g) were rendered neutropenic by 2 doses of cyclophosphamide on day-4 and -1; transient nephrotoxicity was induced by uranyl nitrate on day-2. Anesthesised animals were infected with approximately 10^6 CFU of PA [a mixture

of wild-type (WT) ATCC 27853 and its isogenic porin deleted (OprD−) mutant (MIC of 1 mg/l and 4 mg/l, respectively) in a 1000:1 ratio] intratracheally under laryngoscopic guidance. Serum TNF-alpha and IL-6 were measured by ELISA 16 hours after infection. Pharmacokinetics of meropenem in infected animals was determined by a single dose study. Ten animals were treated with either IP meropenem 400 mg/kg every 8 hours or placebo. Treatment was given 2 hours after infection for 4 days. Quantitative assessment of bacterial burden [total and those with reduced susceptibility (⩾3× MIC)] in animal lung tissues was performed at baseline, upon death or at the end of experiment.
Results: Both serum TNF-alpha and IL-6 were found to be significantly elevated in infected animals, compared to controls (p<0.01). The meropenem dose used (400 mg/kg) resulted in a Cmax of 354.1 mg/l and terminal t1/2 of 18.9 minutes. The corresponding T>MIC for the WT and OprD-mutant were 33% and 26%, respectively. Meropenem therapy offered a significant survival benefit at day 4 (100% vs 0%, p < 0.01), but complete replacement of bacterial population by the OprD-mutant in lung tissue was observed in 30% of the animals.
Conclusion: Our in-vivo results validated previous in-vitro observations that sub-optimal meropenem exposures might facilitate selective amplification of resistant sub-population(s) in a heterogeneous PA population. Optimal dosing regimen design should aim at preventing resistance emergence during treatment, in addition to clinical benefits.

P1063 Itraconazole-ciprofloxacin interaction on the pharmacokinetics of the intestinal compartment: preliminary results in rats

A. Benini, C. Caveiari, P. Franceschetti, E. Bertazzoni (Verona, IT)

Among their pharmacokinetic characteristics fluoroquinolones (FQs) exhibit transintestinal and biliary elimination; moreover, they may interfere with hepatic metabolism. Interactions of FQs with enzymeinhibitors or inducers could be possible during therapy. The inhibitory effects on the hepatic metabolism of Itraconanzole (Itz) should be considered in the kinetics of FQs.
Objectives: To study the effect of Itz on intestinal kinetics of Ciprofloxacin (Cpx) following different administration schedule.
Methods: Wistar rats (weight 174.0+12.5 g, mean+SD) divided in three groups were treated as follows: group 1: Cpx, 15 mg/kg/day, orally administered by gavage for three days; group 2: Cpx two hours after oral administration of Itz (10 mg/kg/day) for three days; group 3: Cpx for 3 days and Itz (10 mg/kg/day) on the 2nd and 3rd day of Cpx administration. Samples of blood, intestinal and hepatic tissues and faeces were collected after three days of treatment, two hours after the last Cpx administration. Cpx concentrations were determined by microbiological assay (agar-well diffusion method, *K. pneumoniae*, Isosensistest agar).
Results: reported in the table as mean+SD
After three days of Itz administration the levels of Cpx increased significantly in liver and faeces (not significantly) while decreased in serum (1/4 positive samples) and intestinal tissues. The administration of Itz for 2 days in rats in treatment with Cpx induced a significant increase of Cpx serum levels, a reduction of intestinal levels and a marked decrease in faeces in comparison to Cpx alone.

Drugs	Serum (mg/L)	Intestinal tissue (mg/kg)	Liver (mg/kg)	Faeces (mg/kg)
Cpx	0.05±0.01 (5/5)	10.4±12.2	0.0±0.0	231.6±279.9
Cpx + Itz 3 days	0.06 (1/5)	4.2±2.7	1.0±0.3**	367.3±264.9
Cpx + Itz 2nd-3rd d	0.2±0.2* (5/5)	7.2±2.4	0.0±0.0	111.8±29.7

*p < 0.05, **p < 0.01 Students t test versus Cpx alone

Conclusions: These preliminary results suggest a possible involvement of Itz on the intestinal secretory mechanisms of Cpx and changes in the enterohepatic circulation. The inhibitory effects of Itz on the Cpx intestinal pharmacokinetics seems different according to timing of Itz administration.
MIUR PRIN 2003-Prot. N. 2003051858_003

P1064 Different effect of pre-treatment with phenobarbital on transintestinal elimination of moxifloxacin and ciprofloxacin: preliminary data

E. Bertazzoni Minelli, A. Benini, C. Caveiari (Verona, IT)

The fluoroquinolones (FQ) are widely used in clinical practice, and exhibit pharmacokinetic properties such as good oral bioavailability, transintestinal elimination through the gut, and biliary excretion. FQs can interfere with hepatic metabolism and drug interaction with enzyme inducers may occur. Few data are available about intestinal concentrations of FQs and their pharmacokinetics interactions in the gastrointestinal compartement.
Objectives. To study the effect of phenobarbital (Phe, enzyme inducer) on intestinal, hepatic and faecal concentrations of Moxifloxacin (Mxf) and Ciprofloxacin (Cpx).
Methods. 30 Wistar rats (180.2+/-7.8 g weight, mean+SD) were divided in 6 groups and treated as follows: group1: Phe (80 mg/kg/day, i.p.) and Mfx (10 mg/kg/day, po) 2 hours later; group 2: Phe (80 mg/kg/day, i.p.) and Mfx (50 mg/kg/day, po) 2 hours later; group 3: Phe (80 mg/kg/day, i.p.) and Cpx (15 mg/kg/day, po) 2 hours later; group4: Mfx (10 mg/kg/day, po); group 5: Mfx (50 mg/kg/day, po); group 6: Cpx (15 mg/kg/day, po). Samples of blood, intestinal and liver tissues, and faeces were collected after three days, 2 hours after the last FQs administration. Cpx and Mxf concentrations were determined with microbiological method (agar diffusion, *K. pneumoniae*, Isosensitest agar).
Results. Mfx was not detected when administered at 10 mg/kg/day; pre-treatment with Phe induced no modifications. Higher doses of Mxf (50 mg/kg/day) produced good intestinal concentrations (10.3+/-5.5 mg/kg) that increased to 16.3+/-4.3 mg/kg in rats pretrated with Phe. Faecal concentrations of Mfx are similar in the two treated groups (280.0+/-32.1 mg/Kg). Mfx was not detected in serum and hepatic tissue. Cpx: Intestinal concentrations of Cpx were 10.4+/-12.2 mg/kg, when administered alone, and 24.8+/-23.7 mg/kg in rats pretreated with Phe; parallel respective serum levels showed a slight decrease(0.04 and 0.02 mg/L, respectively). Cpx was detected only in liver of rats pretreated with Phe. Faecal concentrations of Cpx were 231.6+/-279.9 mg/kg when administered alone and 87.0+/-44.0 mg/kg in rats pretreated with Phe.
Conclusions. The enzyme inducer Phe produced an increase of the concentrations of Mfx and Cpx in the intestinal tissue. Mfx and Cpx showed different behaviour in the intestinal compartment. Phe can modify the pharmacokinetics of Cpx and, in minor extent, that of Mxf.
MIUR PRIN 2003-Prot. N. 2003051858_003

P1065 In vivo efficacy of moxifloxacin monotherapy against clinical isolates of *B. fragilis* with intermediate susceptibility

M. Glenschek-Sieberth, K. Merfort, S. Obertegger, I. Kneževic, R. Endermann (Wuppertal, DE)

Objectives: Moxifloxacin (MXF) is the only marketed fluoroquinolone with FDA approval for the monotherapy of complicated intra-abdominal infections. The obligate anaerobic bacterium, *Bacteroides fragilis*, is implicated in intra-abdominal infections. In this study, the antibacterial efficacy of MXF against clinical isolates of *B. fragilis* with intermediate susceptibility (4 mg/L) was evaluated using a murine granuloma pouch model. Breakpoints (susceptible ⩽2 mg/L, intermediate=4 mg/L, resistant ⩾8 mg/L) for *B. fragilis* were defined by CLSI.
Methods: Twenty clinical isolates of *B. fragilis* (MIC=4 mg/L) and *B. fragilis* ATCC 25285 (MIC=0.5 mg/L) were used. Pouches for the murine granuloma pouch model were created by injecting 5 mL of air and 0.5 mL of 0.1% croton oil in olive oil under the skin of the back. After removing the air (day 3), a bacterial suspension was injected into the pouch (day 5). Infected mice were treated with MXF

100 mg/kg IV, b.i.d. for 2 days. This dose simulates the AUC of the human 400 mg once-daily MXF IV dosage. To compare the efficacy of MXF with piperacillin/tazobactam (PIP/TAZ), three of the strains (the ATCC 25285 strain and two intermediate isolates) were studied in the pouch model. Mice were treated with PIP/TAZ 400 mg/kg IV, b.i.d., a dose that simulates the human PK/PD driver time above MIC of 3.375 g q.i.d. PIP/TAZ IV therapy.
Efficacy was assessed by the reduction in colony forming units (CFUs) in pouch exudates 48 hours post-infection compared with the infection control.
Results: MXF, 100 mg/kg b.i.d., achieved a CFU reduction of >99.9% in 15/20 intermediate susceptible strains, >99% in 3/20 strains and >90% in 1/20 strains. A CFU reduction of <90% only occurred in 1/20 strains. The comparison of MFX and PIP/TAZ demonstrated similar efficacy against the ATTC strain and the two clinical isolates despite the differences in the breakpoint category (intermediate [MXF] vs susceptible [PIP/TAZ]).
Conclusions: In a murine granuloma pouch model, MXF achieved a CFU reduction of >2 logs against 90% of clinical *B. fragilis* isolates with intermediate susceptibility (4 mg/L). Furthermore, MXF was as effective as PIP/TAZ against two strains that were intermediate for MXF but susceptible to PIP/TAZ.

Sepsis

P1066 Red blood cell deformability in diabetic patients suffering from severe sepsis

C.A. Gogos, T. Moutzouri, D. Dimitropoulou, H. Bassaris, G. Athanassiou (Patras, GR)

Objectives: Diabetes mellitus and sepsis are accompanied by haemorheological abnormalities, which cause a secondary hyperviscosity syndrome involved in the pathogenesis of microvascular complications. The diabetic patients are more vulnerable to infections and sepsis is a major cause of morbidity and mortality in diabetes. The aim of the present study was to investigate the impairment of RBC deformability on a series of patients with sepsis, diabetes mellitus and diabetic patients suffering from severe sepsis.
Methods: Forty patients with severe sepsis, no history of diabetes mellitus and normal baseline glucose values, 12 patients suffering from diabetes and no infection and 24 diabetic patients with severe sepsis were enrolled in the study. All septic patients were admitted in the Department of Medicine of Patras University Medical School during a period of 6 months, while diabetic non-septic patients were enrolled from the outpatient clinics of the Endocrinology Unit. RBC deformability was measured using a filtration method based on the initial flow rate conditions of blood samples suspension by using a Nuclepore membrane based Haemorheometer. Values are expressed as the Index of Rigidity (IR)and high IR values indicate low RBC deformability
Results: We observed no differences in severity, organ dysfunction and final outcome between diabetic and non-diabetic septic patients. Mean SAPS II score was 23.5% vs 26.8% in non-diabetic and diabetic septic patients accordingly. The mortality in the group of non-diabetic septic patients was 22.5% and in the group of septic diabetics 34.3%, while septic shock occurred in 15.0% and 20.8% accordingly. Patients with sepsis and patients with diabetes mellitus had significantly ($p < 0.01$)higher IR than healthy controls (13.9±2.86 and 12.26±2.28 vs 8.46±1.21, accordingly. Most significantly, diabetes mellitus and severe sepsis had an additive effect on RBC deformability, as IR in those patients was significantly higher than patients with diabetes and sepsis alone (17.72±6.31).
Conclusion: It seems that both diabetes mellitus and severe sepsis compromise the RBC deformability and increase the RBC rigidity index. Interestingly, when they co-exist, they seem to have additive effects. This supports the hypothesis that the presence of diabetes mellitus further affects the already compromised deformability of the red blood cells and this may contribute to the microcirculatory functional impairments in septic diabetic patients.

P1067 Alterations of innate and adaptive immune responses of patients with septic syndrome due to ventilator-associated pneumonia

A. Pelekanou, A. Kotsaki, I. Vaki, V. Karagianni, H. Kranidioti, E. Spyridaki, E.J. Giamarellos-Bourboulis (Haidari, GR)

Objectives: Sepsis is the clinical expression of deregulated immune response. This study aims at investigating the expression of immune system components in septic patients with ventilator-associated pneumonia (VAP), the leading cause of morbidity and mortality among nosocomial infections in intensive care units.
Methods: Peripheral venous blood was sampled from 52 patients with sepsis, severe sepsis or septic shock (according to ACCP/SCCM 1992 criteria) within 24 hours of diagnosis. Twenty six suffered from VAP; 26 from other infections, namely pyelonephritis, bacteraemia and intraabdominal infection, all well-matched for severity, age and sex and they were used as controls. After lysis of red blood cells with ammonium chloride, white blood cells (WBCs) were stained by FITC-conjugated monoclonal antibodies for CD3, CD19, CD14, Annexin-V, and PE-conjugated antibodies for CD4, CD8, CD(16+56) and HLA-DR. Flow cytometry was used to determine subpopulations of mononuclear cells, apoptosis and HLA-DR expression.
Results: In patients with VAP, median expression of CD3/CD4, CD3/CD8, CD3/CD(16+56), CD(16+56) and CD19 was found in 35.01%, 21.29%, 4.02%, 8.91% and 8.89% of WBCs respectively. Moreover, expression of Annexin-V (marker of apoptosis) on monocytes, T-helper and T-cytotoxic lymphocytes was 15.39%, 4.90% and 2.98% respectively. CD(16+56) expression was positively correlated to both CD3/CD8 and CD14/HLA-DR (p 0.026 and 0.019 respectively). Median CD14/HLA-DR in patients with VAP was 56.88% and in controls 73.17% (p 0.046). Respective expression of CD3/CD(16+56) was 4.02% and 6.62% (p 0.025) and of CD(16+56) 8.92% and 18.07% (p 0.011).
Conclusions: In patients with VAP increased immunoparalysis is found as evidenced by lower CD14/HLA-DR expression. This is accompanied by decrease of T-LGL and NK cells and may explain increased mortality observed among patients with VAP. It may also constitute a future therapeutic target.

P1068 Triggering receptor expressed on myeloid cells (TREM-1) gene expression in critically ill patients

A. Kotsaki, I. Vaki, I. Dimopoulou, H. Kranidioti, S. Orfanos, A. Pelekanou, E. Giamarellos-Bourboulis, A. Armaganidis (Haidari, Athens, GR)

Objectives: Triggering receptor expressed on myeloid cells (TREM-1) is a recently discovered receptor on monocytes and neutrophils. When stimulated, TREM-1 amplifies the toll-like receptor(TLR)-initiated response to invading pathogens allowing the secretion of pro-inflammatory chemokines and cytokines. Our aim was to estimate TREM-1 mRNA levels in critically ill patients.
Methods: Ten ml of heparinised venus blood were collected upon admission from 14 critically ill patients, five with systemic inflammatory response syndrome (SIRS) and nine with severe sepsis/septic shock (ACCP/SCCM criteria). Peripheral blood mononuclear cells were isolated. RNA was extracted after trizol and chloroform treatment and cDNA was synthesised. Expression of mTREM-1 was estimated by real time PCR against the expression of reference gene of beta-2-microglobulin. RNA isolated from PBMCs of healthy donor was applied, as control.
Results: Quantification of mRNA transcription levels using PFAFL equation showed that the levels of mRNA were higher in patients with SIRS (range 2.9×10^3–1.5×10^7, median 1×10^6 copies) compared to patients with severe sepsis (range 13.3–3×10^6, median 1×10^3 copies).
Conclusions: Although former results using flow cytometry analysis has showed that TREM-1 receptor is up regulated in sepsis, pronounced TREM-1 gene expression was found in SIRS compared to severe sepsis/septic shock. These results render the hypothesis that when

TREM-1 receptors reach a critical amount to amplifie the inflammatory response, internal signals stop further mTREM transcription.

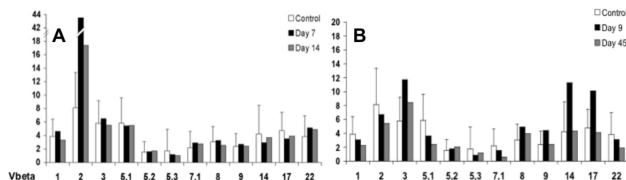
P1069 Detection of superantigenic toxin Vbeta T-cell signatures during menstrual and non-menstrual staphylococcal toxic shock syndrome but not during *S. aureus* septic shock

T. Ferry, T. Perpoint, D. Thomas, A. Lepape, O. Dauwalder, G. Monneret, C. Badiou, C. Chidiac, F. Vandenesch, J. Etienne (Lyon, FR)

Objectives: To detect in vivo production of superantigenic toxins early after onset of staphylococcal toxic shock syndrome (TSS) and septic shock by identifying superantigenic toxin discriminant Vbeta signature (DVbS) in patient's peripheral blood mononuclear cells (PBMC).

Methods: Patients with *S. aureus* TSS or septic shock were prospectively enrolled in Lyon, France, during one year. The Vbeta repertoire of each patient was determined by flow cytometry at the onset of shock after purification (by Ficoll density gradient sedimentation) of PBMC labeled with anti-CD3 and 24 anti-Vbeta antibodies. The toxin gene content of all *S. aureus* isolates was determined by multiplex PCR. We determined which Vbeta subset was significantly expanded in the presence of each superantigenic toxin gene (i.e. the DVbS of a given superantigenic toxin) in vitro with PBMC from healthy donors incubated nine days with culture supernatant of each isolates.

Results: 14 patients were included, 5 with TSS (including 3 menstrual) and 9 septic shock. Patient with septic shock, in comparison with patients who had TSS, were older (61 vs 30 years), were lymphopenic (0.8 vs 2.5 G/L), had more frequently a medical history of immunosuppression (44% vs 0%) and had a higher mortality rate (56% vs 0%). In vitro, the DVbS were as follows: TSST-1: Vbeta 2; SEA: Vbeta 9, 22; SEB: Vbeta 3, 14, 17; SED: Vbeta 1, 8; egc: Vbeta 5.3, 7.1, 9, 23; and SElK: Vbeta 5.1. The DVbS of TSST-1 and SEB were detected in patients with menstrual and non-menstrual TSS (Figure, panel A and B, respectively), whereas no Vbeta signature was detected during septic shock (despite isolates produced superantigenic toxins in vitro).



Conclusion: Early analysis of the Vbeta T cell repertoire in patients with staphylococcal TSS: (i) is useful for detecting the superantigenic toxin DVbS; (ii) may help to confirm the diagnosis of TSS and hasten the administration of anti-toxin therapy. During septic shock, this approach failed to demonstrate superantigenic toxin involvement. However, a medical history of immunosuppression and lymphopenia due to apoptosis in this patient population may limit the expansion of targeted T cells.

P1070 Evaluation of serum TNF-alpha, IL-10, leptin, CRP levels as prognostic markers in patients with sepsis and septic shock

S. Cesur, A. Sengul, Y. Kurtoglu, S. Arslan Ozel, Y. Kalpakci, A. Bilgeturk, S. Kinikli, H. Erdem, Z. Biyikli, C. Eyigun, C. Bulut, T. Aslan (Ankara, Istanbul, TR)

Aim: The aim of this study was to determine the diagnostic value of serum TNF-alpha, IL-10, leptin, CRP levels in differentiating sepsis from septic shock and the prognostic value of these evels in predicting mortality or outcome in patients with sepsis and septic shock.

Material and Methods: Forty-sixth patients with sepsis (32 of sepsis and 14 of septic shock) and 50 healthy subjects were inluded in the study. Serum TNF-alpha, IL-10, leptin, CRP levels were compared between patients with sepsis and septic shock and healthy subjects and the prognostic value of these markers in predicting mortality were determined. For this aim, before treatment(1st day) and during the 3rd and 5th days of treatment serum TNF-alpha, IL-10, leptin, CRP levels were compared between patients with sepsis and septic shock and with those of healthy controls. For statistical evaluation, Mann-Whitney and Fisher's Exact tests were used.

Results: Serum CRP levels were significantly lower in patients with septic shock than sepsis before treatment. On the 3rd day of treatment, there was no difference in any parameter other than CRP levels. While serum CRP levels were found to be low in patients with sepsis on 3rd day, they were increased in patients with septic shock. On the 5th day of treatment, no difference was found in any parameter between patients with sepsis and septic shock.

In the patient group (both sepsis and septic shock), in the comparison between patients who survive and those who die, no difference was found in the parameters before treatment except for IL-10 levels, serum IL-10 levels being higher in the patients who died. On the 3rd day of treatment, serum TNF-alpha and CRP levels were different between surviving and dying patients. Serum TNF-alpha and CRP levels were higher in dying patients than those in surviving patients. On the 5th day of treatment, merely serum TNF-alpha levels were different between dying and surviving patients, values being higher in dying patients.

Conclusion: When the diagnostic value and prognostic values of these markers were evaluated, CRP levels were useful in discriminating between sepsis and septic shock before treatment and on the 3rd day of treatment, whilst IL-10 and TNF-alpha levels were useful in predicting mortality in patients with sepsis before treatment and on the 5th day of treatment respectively.

This project was supported by Scientific and Technical Research Council of the Turkish Republic with project number of SBAG-2841(104S358).

P1071 Risk factors for meticillin-resistance among patients with *Staphylococcus aureus* sepsis

M. Lupse, M. Flonta, A. Almas, M. Suciu, V. Zanc (Cluj-Napoca, RO)

Community-acquired infections caused by meticillin-resistant *Staphylococcus aureus* (MRSA) seem to be increasing. Characteristics permitting recognition of patients with such strains would aid infection control efforts and choice of empiric therapy pending culture and susceptibility. The aim of the study was to develop an objective mechanism to estimate the probability of meticillin resistance in a given patient with *Staphylococcus aureus* sepsis.

Material and Method: Retrospective review of medical records for all adults patients having at admittance in ICU Teaching Hospital of Infectious Diseases (Ian 2006-sept 2007) the diagnosis criteria for sepsis, according to ACCP/SCCM expert panel recommendation, and staphylococcal aetiology. Risk factors for the presence of meticillin resistance in *Staphylococcus aureus* isolates recovered from patients with staphylococcal sepsis were assessed.

Results: From 285 adult patients non-HIV with sepsis (27% nosocomial sepsis), we selected 50 cases (17.54%) with confirmed *Staphylococcus aureus* aetiology. Median age was 51.6 years, 26 males (52%). The MRSA rate was 30%. Of 7 characteristics included in the logistic regression (age, hospital onset, number of SIRS criteria, skin ulcers, respiratory involvement, shock, positive blood cultures), the only independent feature for MRSA was hospital onset ($p = 0.04$)

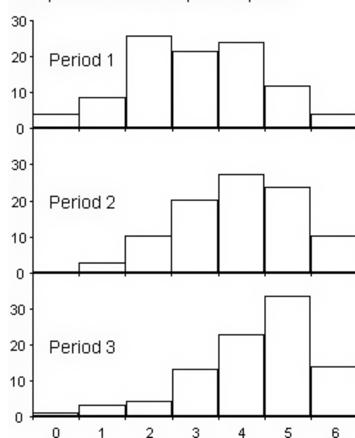
Conclusions: Through multivariate modeling techniques we confirm that nosocomiality is the most important determinant for MRSA and that patients with MRSA bacteraemia were not significantly older or more severe than those with meticillin-sensitive *Staphylococcus aureus* bacteraemia.

P1072 Recognising patients with sepsis in the emergency department before and after protocol implementation

M. Tromp, D. van den Berg, L. Peters, M. Hulscher, T. van Achterberg, B.J. Kullberg, P. Pickkers (Nijmegen, NL)

Objectives: The aim of the present study is to evaluate the effects of implementation of the Surviving Sepsis Campaign guideline in all septic patients in the Emergency Department (ED). Patients ⩾16 years

with sepsis in the ED at a 953 beds University Medical Centre in The Netherlands were included in the study.
Methods: Data were collected and analysed by means of a prospective cohort study from July 2006 to August 2007. The inclusion criteria were: (suspicion of) an infection AND presence of ⩾2 SIRS criteria extended with an altered consciousness, cold chills, SBP < 90 mmHg, MAP < 65 mmHg, hyperglycaemia in the absence of diabetes mellitus.
A multidisciplinary team developed the new sepsis guideline for nurses and doctors in the ED, which was introduced at the ED in November 2006.
The six major actions (6 items bundle) which were included in the sepsis guideline are: measure lactate ⩽6 hrs, take 2 blood cultures before start antibiotics, start antibiotics ⩽3 hrs, perform a chest X-ray, take urine for sediment and culture and hospitalise or discharge the patient ⩽3 hrs.
Results: 765 patients (451 men, 314 woman) with sepsis in the ED were included in the study. 159 patients before protocol implementation (period I), 447 patients after introduction of the protocol (period II) and 159 patients were included after presentation of the first results (period III). Compliance with the six major actions described in the methods (1 point earned per item) improved significantly ($p < 0.0001$) as illustrated in the figure. Hospital length of stay was median [25–75%range] 6 [2–12], 7 [3–12], 6 [3–11] days in period I, II and III, respectively. The hospital mortality rate was 6.3, 6.0 and 5.0% in period I, II and III, respectively (p=NS).
Conclusion: Implementation of a sepsis guideline resulted in a significant improvement of the compliance to the guideline. This improvement tended to be associated with a decrease in hospital mortality.
The management, diagnosis and treatment for patients with sepsis in the ED can be improved by implementation of a sepsis guideline.



P1073 Early pattern of IL-6, TNF-alpha, IL-12 and IFN-gamma levels in septic patients

S. Mera, C. Cismaru, V. Zanc, D. Tatulescu, M. Flonta, D. Carstina (Cluj-Napoca, RO)

Objectives: Overcoming severe infections requires effective response involving both the innate and adaptive immunity. Priming and modulation of the immune response are driven by bacterial products and several endogenous mediators, such as cytokines. We analysed several proinflammatory cytokines in the early sepsis and studied their correlation with aetiology and severity.
Methods: In 24 septic patients we analysed serum levels of IL-6, TNF-a, IL-12 and IFN-g at day 1, 2, 3 and 7 upon admission. Patients (19 males/5 females) had the median age of 65.5. The primary infection had urinary (11), respiratory (11), dental (1) and cutaneous (1) origin. 14 healthy volunteers served as controls.
Results: At admission, median PCT was 10 ng/ml (0.5–10) and median SOFA score was 6 (range 1–11). 5 patients (17%) died during the first week. IL-12 and IFN-g were undetectable both in controls and septic patients at all time-points. Septic patients had median TNF-a concentration of 6 pg/ml at admission and decreasing at the following time-points, while in controls TNF-a was undetectable. In septic patients, IL-6 had a median level of 78 pg/ml at day 1 and decreased at 38 pg/ml, 9.15 pg/ml, 2.97 pg/ml at day 2, 3 and 7 respectively. Patients with severe sepsis (n = 38) had the highest IL-6 levels, reaching a median of 102.2 pg/ml, patients with sepsis had a median value of 61.2 pg/ml while IL-6 in controls was 1.78 pg/ml. TNF-a showed similar levels and kinetics between urinary and respiratory sepsis, yet in respiratory sepsis IL-6 increased more prominently. Gram-positive sepsis led to higher amounts of circulating TNF-a and IL-6, reaching 23.6 pg/ml and 130 pg/ml respectively while in Gram-negative sepsis, median levels of TNF-a and IL-6 were 6.6 pg/ml and 60 pg/ml respectively. Two non-survivors had very high IL-6 at day 1 (over 1000 pg/ml) that did not follow the descendent trend of IL-6 levels at next time-points.
Conclusions: During early sepsis, a rapid inflammatory response is mounted and driven by the innate immunity, yet excessive response may prove detrimental. Since we did not detect circulating levels of IL-12 and IFN-g, it appears that sepsis does not to elicit an adaptive immune response in its early phases. The low levels of TNF-a are maybe due to the short half-life of the molecule. IL-6 release might be influenced by the primary site of infection and aetiology, and it could serve as a potential routine, reliable parameter in monitoring septic patients.

P1074 Statins for infection and sepsis – A systematic review of the clinical evidence

M. Falagas, G. Makris, D. Matthaiou, P. Rafailidis (Athens, GR)

Objective: Statins are currently used for hyperlipidaemia control and considered useful in protecting from cardiovascular events. In addition, there is increasing use of evidence for the potential use of statins in treating infections.
Methods: We performed a systematic review of the literature that compared the outcome between statin and non-statin users among patients suffering from sepsis or other infections (bacteraemia, pneumonia, ICU infection, viral infection and other bacterial infection). The relevant studies were identified from searches of the PubMed and the Cochrane Library Databases.
Results: Twenty studies were identified out of which 9 examined the use of statins in patients with sepsis, bacteraemia, or multi-organ dysfunction syndrome, 4 community acquired pneumonia (CAP), 1 ICU infections, 2 other bacterial infections, and 4 viral infections. In total, 11 studies had data regarding mortality as the main outcome: 8 showed decreased mortality in statins users (3 of them reported on patients with bacteraemia), 2 showed no difference in mortality and 1 reported an increased mortality in patients who received statins. Seven studies examined the risk of sepsis as the main outcome; 6 of these studies showed a decreased risk of sepsis in patients receiving statins, while one study found no difference.
Conclusion: The majority of the studies suggest that statins may have a positive role in the treatment of patients with sepsis and infection. However, the reviewed studies have several methodological limitations. Conclusions regarding this important clinical question should wait for the results of ongoing relevant randomised controlled trials.

P1075 Anti-platelet activating factor effects of antibiotics: a new insight into therapy of sepsis?

A. Tsoupras, M. Chini, N. Tsogas, A. Lioni, G. Tsekes, C. Demopoulos, M. Lazanas (Athens, GR)

Objectives: There are data supporting the role of inflammatory mediators, such as anti-platelet activating factor (PAF), in sepsis. These molecules can act in synergy with infectious agents to initiate and propagate the disease process. In animal models, beneficial effects have been observed as a result of treatment with various antagonists of PAF;

however the precise role of PAF as mediator of the diffuse inflammatory state characteristic of sepsis remains to be determined.
Methods: In order to examine the possible interactions between PAF and antibiotic treatment, we studied the effect of different compounds against PAF biological activity. We assessed the in vitro inhibitory effect of various compounds against PAF-induced aggregation on washed rabbit platelets by evaluating the IC50 of each drug. We also studied the in vitro effect of these drugs against rabbit plasma PAF-AH (the main degradating enzyme of PAF) and PAF-CPT (the main de novo biosynthetic enzyme of PAF) of washed rabbit leukocytes.
Results: Clarithromycin, azithromycin, linezolid, amikacin, netilmicin and piperacillin/tazobactam exhibited IC50: 0.06, 0.1, 0.29, 0.73, 0.74 and 4.92 μg/μL respectively. Concentrations equivalent to their IC50 values against PAF activity, inhibited in vitro the PAF-CPT activity of washed rabbit leukocytes. Furthermore, clarithromycin and azithromycin in concentrations of a log10 higher than their IC50 values against PAF, increased in vitro the rabbit plasma PAF-AH (table 1).

Drug	μg/μL	% Inhibition of PAF-CPT	% Increase of PAF-AH
Clarithromycin	0.04	59.09	
	0.21		34.73
Azithromycin	0.16	34.85	
	1.56		40.12
Piperacillin/tazobactam	2.81	62.94	
Amikacin	0.31	60.26	
Netilmicin	0.5	47.68	
Linezolid	0.25	51.22	

Conclusion: Many antibiotics exhibit high inhibitory effect against PAF-induced washed rabbit platelet aggregation and its main de novo biosynthetic enzyme PAF-CPT while only clarithromycin and azithromycin seem to activate plasma PAF-AH. The promising in vitro results need to be further studied and confirmed by in vivo tests, in order to optimise the efficacy of antibiotic treatment in sepsis.

P1076 The natriuretic peptide (BNP) as a marker of sepsis

C. Petrocheilou, A. Karaferi, M. Pouyiouka, V. Karabasi, C. Achilleos, A. Nitsa, M. Toutouza (Athens, GR)

Objective: The discovery of a reliable marker for sepsis is of great significance for the on time management and survival of septic patients. The aim of the study is the evaluation of the reliability of the Natriuretic peptide (BNP) as a marker of sepsis in comparison to C Reactive protein.
Methods: We studied 58 patients of the ICU in a year period. They were separated into 2 groups. Group A with 8 non septic patients and Group B with 50 patients suffering from great sepsis and septic shock. Blood samples were taken from all patients at their admittance and at days 2, 3, 4, 6, 8 and 10. The levels of BNP were analysed with microsomatic immunoenzyme method (AXSYM – ABBOT) (Normal value <100 pg/ml) and the levels of CRP with nefelometry (Normal value <5 mg/ l).
Patients with heart failure were excluded from the study.
Results: The mean value of BNP in Group A was 24.2 pg/ml, while the mean value of BNP in Group B was 971.2 pg/ml. The difference is statistically important.
The mean value of CRP in Group A was 103.3 mg/l, while in Group B it was 107.062 mg/l. The difference has no statistical importance.
Conclusion: The evaluation of the results seem to drive to the conclusion that the levels of BNP are reliably increased in patients with great sepsis and septic shock and may be a valuable diagnostic tool.

P1077 Diagnostic value of the soluble triggering receptor expressed on myeloid cells-1 in critically ill patients with suspected sepsis

L.F. Li, X.D. Guan (Guangzhou, CN)

Objective: To evaluate the diagnostic and prognosis value of plasma levels of the soluble triggering receptor expressed on myeloid cells-1 (sTREM-1) in critically ill patients admitted with clinical suspicion of sepsis.
Methods: All consecutive adult patients, who were newly hospitalised in the surgical intensive care unit (SICU) from January to October 2006, were prospectively enrolled in this study if they had clinical suspected infection and fulfilled at least 2 criteria of the systemic inflammatory response syndrome (SIRS). Patients were not enrolled if they were older than 80-year-old, were immunocompromised, died or were discharged within 12 hours after admission. Within 12 hours after enrollment, the levels of plasma sTREM-1 and CRP, TNF-Alfa, IL-6, procalcitonin (PCT) were measured, and the microbiological cultures were performed. Base on the results of cultures and the decision of intensivists, all patients were classified into different groups as SIRS (no infection), sepsis, severe sepsis, or septic shock. The levels of plasma sTREM-1 and CRP, TNF-Alfa, IL-6, and PCT in different groups were compared.
Results: There was a significant difference of median plasma sTREM-1 levels at admission between different groups (68.8 pg/ml in SIRS group, 69.7 pg/ml in sepsis group, 106.2 pg/ml in severe sepsis group, 373.5 pg/ml in septic shock group, $P < 0.001$). The capacity of Plasma sTREM-1 to differentiate the presence of sepsis or septic shock was assessed with a receiver-operating-characteristic curve (ROC) analysis. The area under the ROC when Plasma sTREM-1 was used to differentiate the presence of sepsis was 0.82 (95% CI, 0.70–0.94, $P < 0.001$). The area under the ROC when Plasma sTREM-1 was used to differentiate the presence of septic shock was 0.96 (95% CI, 0.90–1.0, $P < 0.001$). Only sTREM-1 was found to be an independent predictor of the prognosis with sepsis. The area under the ROC was 0.87(95% CI, 0.77–0.97, $P < 0.001$), when Plasma sTREM-1 was used to prognoses the presence of death in sepsis patients.
Conclusion: There were higher plasma sTREM-1 levels in critically ill patients with sepsis syndromes. TREM-1 was an effective indicator of diagnosis of sepsis and septic shock, and also an effective prognosis risk predictor of sepsis in critically ill patients.

P1078 Comparison of procalcitonin with interleukin 8, leucocyte count and rate of immature to total neutrophils for the early diagnosis of severe bacterial pneumonia and sepsis in pre-term infants

G. Dementyeva, M. Kushnaryova, E. Chursina (Moscow, RU)

Objective: To evaluate procalcitonin (PCT) as a test for early diagnosis of bacterial pneumonia and sepsis in preterm infants and to compare the results of PCT with those of interleukin 8 (IL-8), leucocyte count, rate of immature to total neutrophils (I/T).
Subjects and Methods: Serum PCT (BRAMS PCT-Q™) was prospectively measured along with IL-8 (ELISA), leucocyte count in 82 preterm infants, 26–36 wk of gestation. Preterm infants were classified to two groups according to their infections status: (1) 48 preterm infants with severe bacterial pneumonia and sepsis (positive blood cultures), (2) 34 noninfected preterm infants wiht respiratory distress syndrome (RDS). PCT, IL-8, leucocyte count, I/T were analysed for sensitivity, specificity and positive and negative predictive values.
Results: At a cut off value of 2ng/ml, the sensitivity of PCT was 92% and specificity was 97%. The positive and negative predictive values of PCT in the diagnosis equalled 97.7% and 89.1%, respectively. Sensitivities for IL-8 (⩾70ng/ml), leucocyte count (⩾15·109/l) and I/T (⩾0.2) was 50%, 66%, 35% and specificities – 94%, 71%, 88%, respectively.
Conclusion: PCT was the most specificity and sensitive diagnostic parameter in the diagnosis of severe bacterial pneumonia and sepsis.

A PCT concentration ⩾2ng/ml might be useful in differentiating severe bacterial pneumonia and sepsis in preterm infants.

P1079 Comparison of neutrophil volume distribution width with C-reactive protein and procalcitonin for diagnosis of culture-proven sepsis

J.S. Lin, H-C. Tai, S-F. Kuo, S-L. Young (Changhua, TW)

Objectives: Rapid diagnosis of bloodstream infection is problematic due to time-consuming blood culture. Current biomarkers in diagnosis of sepsis either lack of sensitivity and specificity or are expensive. Neutrophil volume distribution width (NDW) which is generated on the hematology analyser when measuring complete blood count has been demonstrated by Chaves et al (2005) as a potential predictor of sepsis in a fast and cost-effective manner. However, its clinical usefulness remains un-established. In this study, NDW values were compared with plasma concentrations of C-reactive protein (CRP) and procalcitonin (PCT) for diagnosis of culture-proven sepsis.
Methods: Within 12 hours of blood culture submission, NDW and concentrations of CRP and PCT of peripheral blood samples were retrospectively reviewed or analysed. After exclusion of contaminated samples in blood culture, only laboratory data obtained from patient samples of positive bacterial blood culture were recruited for comparison with those of negative culture. Among them, NDW, CRP and PCT were measured using VCS technology of LH750 hematology analyser (Beckman Coulter), immunoturbidometry (COBAS INTEGRA 800, Roche Diagnostics) and enzyme-linked fluorescent assay (VIDAS BRAHMS PCT, bioMerieux), respectively. Positive blood culture was used as the gold standard for diagnosis of sepsis. Receiver operating characteristic (ROC) curve was constructed and area under ROC curves (AUC) was determined for evaluation of diagnostic power.
Results: Laboratory data of 194 unrelated patients (age of range, 0–101 years), were collected. Of them, 60 and 134 had positive and negative bacterial culture, respectively. To predict bacteraemia, NDW had a similar AUC (0.78 [0.70–0.85], $p < 0.001$) as PCT (0.80, [0.73–0.87], $p < 0.001$) but CRP had a lower AUC (0.64 [0.56–0.72], $p = 0.002$). The optimal sensitivity and specificity at an appropriate cutoff value were 0.72 and 0.73 at 24.5 for NDW, 0.75 and 0.70 at 0.6 ng/mL for PCT, and 0.59 and 0.56 at 63.3 mg/L for CRP, respectively.
Conclusion: Our preliminary study had demonstrated that NDW had a superior diagnostic accuracy in bacteraemia than CRP as PCT in prediction of bacteraemia. This finding might imply a potential role of NDW for laboratory prediction of culture-proven sepsis in a fast and cost-effective manner.

P1080 Procalcitonin as a diagnostic and prognostic marker in chronically-critically ill patients

H. Tsangaris, D. Kavatha, M. Gourgoulis, D. Plachouras, E. Paramythiotou, E. Karampekiou, A. Armaganidis, H. Giamarellou (Haidari, GR)

Objective: To investigate Procalcitonin (PCT) levels as prognostic markers of infection and to correlate maximum as well as every other day changes of PCT levels to mortality of chronically critically ill patients.
Methods: This is study including all patients hospitalised for more than 10 days in ICU. Blood samples for PCT, WBC, and CRP were drawn every other day. Patients were classified to one of the following groups according to ACCPM 1994 criteria 0: no infection, 1: localised infection and sepsis, 2: severe sepsis and septic shock and SOFA score was recorded. PCT concentrations were measured by an automated immunofluorescent assay (PCT KRYPTOR) PCT values were categorised as alert and non alert values using x-bar test. Maximum PCT (PCT max) levels and number of days with PCT higher than the alert value were compared between survivors and non-survivors. All PCT levels were correlated with CRP, WBC and SOFA score with the Spearman test and compared among the various groups of severity of infection by one-way ANOVA. Categorical variables were compared using the chi-square test and continuous variables with non-parametric Mann–Whitney U test.
Results: PCT plasma concentrations were measured in a total of 169 samples collected from 11 patients (8 male and 3 female) followed up for a mean of 34.5 days (range 14 to 67) until discharge or death. The alert value in this population was calculated as 0.88 ng/ml. Mean PCT (±SD) concentration of patients categorised as having no infection, sepsis and severe sepsis–septic shock were 0.47 (±0.40), 1.86 (±3.86) and 4.82 (±7.58) respectively ($p < 0.0001$). There was a definite but weak correlation between PCT concentrations, CRP (Spearman's rho 0.21, $p < 0.007$) and SOFA score (Spearman's rho 0.3, $p < 0.0001$) but not with WBC. PCT max was 4.33 in survivors and 12.98 in non-survivors (p NS). Mean total days with PCT higher than alert value were 2.44 and 5.66 respectively (p NS)
Conclusions: Mean PCT plasma concentrations correlated to the severity of the infection. There was a weak correlation among PCT, CRP and SOFA score and a trend to higher mean PCT values and to more mean total days above the alert value in non-survivors than survivors.

P1081 Evaluation of F-18-fluorodeoxyglucose positron emission combined with computer tomography (FDG-PET-CT-scan) in critically ill patients suspected of Infection

K.S. Simons, P. Pickkers, C.P. Bleeker-Rovers, J.G. van der Hoeven, W.J.G. Oyen (Nijmegen, NL)

Objectives: During their stay at the intensive care unit (ICU), many critically ill patients are suspected of a focal infectious process. Timely identification and localisation of infection is critical in appropriate treatment of these patients. FDG-PET has shown to be valuable in the evaluation of fever of unknown origin and suspected focal infectious diseases in non-ICU patients, but no studies have been performed in critically ill patients. In this study, the value of FDG-PET-CT-scanning in diagnosing focal infection was studied in ICU patients.
Methods: Between October 2005 and June 2007 all FDG-PET-CT scans ordered in ICU patients for evaluation of persisting fever or suspected focal infection were retrospectively analysed. The final diagnosis was used for comparison with FDG-PET-CT results. A diagnosis was never based on the FDG-PET-CT results alone.
Results: 29 FDG-PET-CT scans were performed in 28 ICU patients (including 4 children, median age 58 years). In fifteen patients FDG-PET was performed because of persisting fever (median duration of fever 17 days) and in 15 patients because of suspected focal infection. Seventeen patients were eventually diagnosed with an infection, one patient with malignant lymphoma, and in 12 cases no diagnosis was reached. The PET-CT scan was performed after a mean ICU-stay of 22 ±2.8 days. No complications occurred during the transportation and scanning procedure. Sixteen FDG-PET-CT scans were classified true positive and were considered to be contributory to the final diagnosis. Three PET-CT scans were considered false positive, in one case leading to additional diagnostic procedures. Additionally, ten true negative and no false negative scans were found. Thus, 84% of the abnormal FDG-PET scans were clinically helpful and FDG-PET contributed to the ultimate diagnosis in 55% of all patients. FDG-PET was considered helpful in 94% of all patients with a final diagnosis.
Conclusion: FDG-PET-CT scanning is of additional value in the evaluation of persisting fever and suspected focal infection in critically ill patients. A normal FDG-PET-CT scan also ruled out a focal infection with a very high negative predictive value.

P1082 Is venous access port inner surface colonisation related with port obstruction?

M. Alonso, A. Martinez, A. Serrera, A. Ramos, J.I. Bilbao, M. Portillo, J. Leiva, J.L. del Pozo (Pamplona, ES)

Objectives: Venous acces ports (VAP) are used in patients receiving long parenteral therapy. However, use of these devices is associated with infectious and mechanical complications. One of the most

common causes of mechanical failure is catheter lumen occlusion. This complication may lead to the removal of the port. Although precipitation of drugs and blood clots can obstruct the device, we propose here that colonisation of the port inner surface may be related to port obstruction. The aim of this study was to analyse if port colonisation and obstruction were associated in a significative way.

Methods: We performed a 27 months prospective study on all the removed VAPs of our hospital. We analysed reasons for removal and we cultured all the removed ports (catheter tip and septum culture after a vortexing-sonication procedure). We compared colonisation ratios on the group of patients whose VAPs were removed because of the obstruction (group 1) and the group of patients whose VAPs were removed because of end of use or because of a mechanical complication other than obstruction (group 2). Patients with port-related infections were excluded. The cut-off to consider the ports to be colonised was >1000 cfu/ml for both cultures (catheter and septum). Differences were statistically analysed using the chi-square test.

Results: From August 2005 to October 2007, 240 VAPs were removed from 240 patients. Ports were removed due to end of use in 187 (77.9%) cases, 34 (14.2%) ports were removed because of infectious complications and 19 (7.9%) because of mechanical complications. Seven of the ports were removed due to obstruction (group 1) and 197 because end of use (group 2). Colonisation rates were 3/7 (42.9%) and 16/197 (8.1%) in groups 1 and 2 respectively. Differences were statistically significative with a p value of <0.019. Coagulase-negative staphylococci were the most frequent isolated microorganisms, followed by *Candida* species.

Conclusions: Data from this study suggest that port colonisation may play a role in the genesis of port obstruction. Antibiotic lock therapy might be useful in this scenario to try to avoid removal because of obstruction. However, more prospective studies are warranted to address this important issue.

Clinical epidemiology of bloodstream infections and occupational blood exposure

P1083 Incidence of central venous catheter-related infection in a community hospital

M. Delgado, J. Yebenes, L. Ballester, G. Sauca, E. Vidal, R. Icart, J. Capdevila (Mataro, ES)

Introduction: Catheter-related infections (CRI) are a main cause of nosocomial bloodstream infections and are related to important morbidity and mortality. In the Spanish Nosocomial Infection Study (EPINE) the prevalence of catheter-related bloodstream infection (CRBI) is between 2.5 and 3.4 episodes per 1000 hospitalised patients.

Objective: To asses the incidence of central venous catheter related bloodstream infections (CRBI) in a community hospital.

Methods: Prospective daily follow-up of all central venous catheters (CVC) inserted in the Hospital de Mataro during a period of 9 months. Main patient's demographic data and catheters characteristics were recorded. All catheters were inserted using full sterile barrier methods. Hubs were closed with disinfectable needleless mechanical valve connectors. Catheters removed by suspicion of infection were semiquantitatively cultured using the roll plate method. Two blood cultures were also performed. According to clinical and microbiological criteria, catheters were classified as: not infection-related, entry-site infection, colonised catheter, and CRBI.

Results: During 9 months 597 catheters were placed in 480 patients, 282 males (58%). Total catheterisation days were 4886. Mean catheterisation days were 8.19 (1–58). Catheters were inserted in the emergency room in 35 cases (5.8%), 151 in surgical theater (25.2%), 45 in others units (7.23%) and 365 in ICU (61%) where a trained and specialised nurse team exists. The subclavian access were used in 194 catheters (32.49%), jugular in 124 (20.7%), brachial in 245 (41%) and femoral in 30 (5.02%). Catheters were removed by end of treatment in 419 cases (70.18%), dysfunction in 42 cases (7.03%), and by fever or suspicion of infection in 40 patients (6.7%). Seven episodes of CRBI were registered, all of them caused by *S. epidermidis*, which results in an incidence rate of 1.43 episodes/catheterisation days. No CRBI was observed during this period in the ICU, resulting in an incidence rate of 0 in ICU and 2.25 episodes/1000 catheterisation days in conventional hospitalisation units.

Conclusion: The incidence of CRBI in our institution is in the accepted normal range. We observe relevant differences in CRBI's rates between conventional hospitalisation units and ICU where a trained and specialised nurse team exists. This suggests the importance of catheter manipulation in the genesis and prevention of CRBI.

P1084 Use of disinfectable needleless mechanical valve connectors and catheter-related bloodstream infection rates in a polyvalent intensive care unit

M. Delgado, J. Yebenes, T. Zaro, M. Perez, E. Lavado, M. Cegarra, A. Dalmau, J. Almirall (Mataro, ES)

Introduction: Disinfectable needleless mechanical valve connectors (DNMVC) have been introduced to avoid needlestick injuries in healthcare workers but they are accompanied by concerns about the possibility of an increase in the risk of catheter-related bloodstream infections (CRBI) associated with their incorrect use. Use of bundles can facilitate the adherence to the handling recommendations.

Objective: To observe the rates of CRBI after the development of a handling bundle in a polyvalent intensive care unit (ICU) where a DNMVC (Smartsite) are used to close the intravenous catheter hubs.

Method: We used a 5 recommendations bundle (nurse implication in the epidemiological surveillance, selection of the safest place of insertion, understand insertion as a surgical procedure, maintain the endoluminal sterility during infusion and avoid unnecessary insertions, manipulations or removals). Every three months data were reported to the nurse shift that was responsible of surveillance and diffusion of the results to the rest of the nurse shifts.

Results: From January to September 2007, a total of 510 catheters were inserted in 229 critically ill patients during more than 24 hours, 273 of they were central venous catheters and 237 arterial lines. The mean length of insertion was 6.3±6.0 days, and it supposes 3227 days of risk. We don't observe any CRBI and 2 primary bacteraemia (0 and 0.62 episodes per 1000 days of risk respectively).

Conclusions: Rates of CRBI and primary bacteraemia were minimal during the 9 months that the observational study was performed (0 and 0.62 episodes per 1000 days of risk). Inclusion of nurses as active part of the epidemiological surveillance can help the implementation of simple recommendations. We can not associate the use of disinfectable needleless mechanical valve connectors with increased rates of catheter-related bloodstream infections.

P1085 Catheter-related bloodstream infection in patients on total parenteral nutrition: 10-year surveillance data in a university teaching hospital in Dublin, Ireland

C.J. Collins, M.H. Fraher, J. Bourke, D. Phelan, M. Lynch (Dublin, IE)

Objectives: Total parenteral nutrition (TPN) is a well-recognised risk factor for catheter-related bloodstream infection (CR-BSI). However, there is limited data in the literature specifically addressing CR-BSI in patients on TPN. Surveillance of CR-BSIs in patients on TPN has been ongoing in the Mater Misericordiae University Hospital (MMUH), a 525-tertiary referral hospital in Dublin for over 10 years. In 1997, a TPN surveillance Clinical Nurse Manager (CNM) was appointed. Protocols re insertion of central venous catheters (CVCs) specifically addressing location of insertion and skin preparation were introduced in 2002. Quarterly TPN committee meetings along with frequent educational sessions were introduced. Our aim was to demonstrate the epidemiology of the organisms causing CR-BSIs in this subset of patients and the impact of the above measures both on the incidence of CR-BSIs and the duration that the CVC remains in situ before infection occurs.

Methods: Data on all patients prescribed TPN has been collected prospectively. Individual cases were reviewed at quarterly meetings over this time period and cases were assigned to appropriate categories as per CDC definitions on CR-BSIs. All CVCs were non-antibiotic impregnated. The data was analysed only for non-tunnelled CVCs.
Results: 194 CR-BSIs in 1,197 patients (total of 12,296 catheter days) on TPN were recorded in the 10-year time period. Staphylococci accounted for over 80% of infections each year with few *Candida* spp. or Gram-negative infections (fig 1). A reduction in the overall incidence of CR-BSI (33.6 to 5.1/1,000 catheter days) and an increase in the duration that the catheter is in situ before infection occurs (mean 4.8 to 8.2 days) was noted.
Conclusions: The high proportion of CR-BSIs in patients on TPN due to staphylococci has important implications for treatment. Glycopeptide therapy alone may be sufficient empirical therapy in this subset of patients unless severely septic. Appointment of the surveillance CNM allied with auditing, feedback, education and insertion protocols led to positive effects on the incidence of CVC infection and catheter duration before infection.

Epidemiology of Organisms (rates/1,000 catheter days)

P1086 Association of platelet parameters and Gram-negative bacteraemias: a case control study

M. Dalamaga, M. Pantelaki, K. Karmaniolas, K. Daskalopoulou (Athens, GR)

Background and Objective: Bacteraemia and sepsis, as uncontrolled generalised inflammatory responses, involve thrombopoiesis and haemostatic mechanisms. Mean platelet volume (MPV), platelet distribution width (PDW), their correlations with platelet count and inflammation markers and their clinical significance have not been studied in bacteraemias in depth. The aim of this study was 1) to determine whether newly diagnosed patients with Gram(–) bacteraemia, in comparison to their controls, would be characterised by ineffective thrombopoiesis, as reflected by MPV and PDW and 2) to explore their correlation with inflammatory markers and their significance in the course of bacteraemia.
Material and Methods: We have evaluated 22 incident cases of Gram-negative bacteraemia (13 men and 9 women, 23–82 years) and an equal number of hospital controls with minor non-infectious and non-neoplastic conditions, individually matched for age (±5 years) and gender and month of diagnosis. To assess thrombopoiesis and inflammation, we have determined platelet count, MPV, PDW and leucocyte count using Sysmex SE-9000 blood analyser. CRP levels were determined using immunonephelometry (Dade-Behring, Germany). Statistical analysis of data was performed with SAS® version 9 software.
Results: Significantly low mean values of MPV and PDW, together with significantly high mean values of platelet count, leucocyte count and CRP were shown in patients with Gram(–) bacteraemia in comparison to their controls ($p < 0.001$). There was not any statistical significant difference in platelet count, MPV, PDW and CRP levels ($p > 0.05$) in patients with Gram(–) bacteraemia based upon the number of leucocytes (those with leucopenia n = 3 and those with leucocytosis n = 37). There was a significant inverse relationship between MPV (and PDW) and platelet count in patients with bacteraemia (r=-0.78; $p < 0.001$) as well as a significant inverse relationship between MPV and CRP (r=-0.52; $p = 0.01$). Adjusting for age, gender and CRP levels, MPV (or PDW) is a significant predictor of bacteraemia. Patients with Gram(–) bacteraemia who responded favorably to antibiotic therapy presented normal platelet parameters after ten days of treatment.
Conclusion: Platelet parameters have been shown to provide an accessible and clinical useful index for estimating the impairment of thrombopoiesis and the degree of inflammation in patients with Gram-negative bacteraemia as well as for predicting favorable response to antibiotics.

P1087 Incidence and risk factors of recurrent bacteraemia due to *Escherichia coli*

J. Villar, A. Rodriguez Aranda, F. Sanz, J.R. Otero, F. Chaves (Madrid, ES)

Objectives: *E. coli* recurrent bacteraemia (RB), defined as relapse or reinfection, is a relevant but not well known clinical process. The aim of this study was to determine the frequency of RB and risk factors for relapse (isolates with the same pulsed-field gel electrophoresis pattern [PFGE]) or reinfection (different PFGE) after a first episode of *E. coli* bacteraemia.
Methods: This is a retrospective study conducted in a tertiary Hospital. RB was defined as a new episode of bacteraemia after at least 1 month since a prior episode sucessfully treated. Patients with RB during 2001–2005 were included. The control group included 41 patients with a single episode of bacteraemia and a year of follow-up. A systematic review of clinical data was performed. Blood isolates were analysed by PFGE and the phylogenetic background studied. We compared demographic, clinical and microbiological variables between relapse or reinfection and control group.
Results: 945 patients had *E. coli* bacteraemia, 32 (3.4%) had RB. We studied blood isolates from 28 patients (4 excluded) with 58 clinical episodes. According to PFGE analysis, 13 patients (46.4%) suffered relapse and 15 (53.6%) reinfection. Relapse occurred earlier than reinfection (median, 56 versus 67 days, $p = 0.02$), and it was caused by strains more resistant to antibiotics. In the comparison with no RB, multivariate analysis showed that patients with relapse were more likely to be younger than 60 years (OR:17.5; $p = 0.05$), admitted in the nefrology unit (OR:246.9; $p = 0.012$), to have received antibiotics previously (OR:15.6; $p = 0.045$) and to be infected with ciprofloxacin resistant strains (OR: 97.0; $p = 0.008$). On the other hand, patients with reinfection were associated with prior hospital admissions (OR: 21.6; $p = 0.027$), being admitted in haematology/oncology units (OR: 19.8; $p = 0.037$), having a central intravascular catheters (OR:60.9; $p = 0.008$), and having a biliary/gastrointestinal source of infection (OR: 20.9; $p = 0.039$). The distribution of phylogenetic groups in relapses was: group B1 38.5%, D 30.8%, B2 23.1%, and A 7.7% and in reinfections was: group B1 33.3%, B2 25.9%, D 18.5%, and A 22.2%.
Conclusions: We have determined the frequency of recurrent *Escherichia coli* bacteraemia in our hospital and delineated some risk factors for relapse and reinfection. Appropriate management for the prevention of further recurrences may need more research on treatment strategies and virulence factors of *E. coli* strains

P1088 Invasive *Staphylococcus aureus* Infections Cohort (INSTINCT)

H. Wisplinghoff, A. Kaasch, K. Achilles, A. Langhorst, G. Peyerl-Hoffmann, A. Wöhrmann, G. Fätkenheuer, B. Salzberger, W. Kern, H. Seifert (Cologne, Freiburg, Regensburg, DE)

Introduction: Nosocomial bloodstream infections (BSIs) are important causes of morbidity and *S. aureus* is one of the most important nosocomial pathogens.
Methods: INSTINCT was established to prospectively monitor clinical features of *S. aureus* BSI (SAB) in Germany using a web-based database. Data are collected by infectious diseases physicians aided by specially trained medical personnel to monitor risk factors, predisposing conditions, portal of entry, clinical course, diagnostic and therapeutic procedures as well as outcome up to one year after SAB.

Results: Between January 2005 and September 2007, 468 cases of SAB were detected in the 3 participating university hospitals. Patients had a mean age of 61 years and 33% were female. Length of stay averaged 33 days. Underlying conditions most often included cardiovascular (35%), or renal (27%) disorders and diabetes mellitus (27%). SAB were classified as nosocomial in 54% of patients another 26% were healthcare-associated. Primary SAB was seen in 61% of cases, of which 28% were catheter-related. Secondary SAB most often originated from skin and soft tissue infections (7%) or surgical wound infections (5%). 18% of *S. aureus* isolates were meticillin-resistant. Severe Sepsis and septic shock at onset of SAB were seen in 4.5% and 2.5% of patients, respectively, secondary complications were reported in 14% of patients, most commonly endocarditis, osteomyelitis or spondylodiscitis. The mean duration of *S. aureus* bacteraemia was 3.5 days. Patients received a mean of 16±13 days of appropriate anti-staphylococcal therapy. Adherence to ID consult recommendations such as TEE (recommended in 50%, followed in 34%) and follow-up blood-cultures (61%; 48%) varied significantly between centres. The crude 7-day-mortality was 15%, in-hospital mortality was 23%.

Conclusion: INSTINCT currently represents one of the most detailed prospective SAB studies. Data from the first years underscore the importance of SAB and confirm the feasibility of this very detailed monitoring design.

P1089 Primary bloodstream infections and catheter-related bloodstream infections in critically ill patients: impact on length of stay and mortality

M. Michalia, M. Kompoti, A. Paridou, G. Kallitsi, A. Koutsikou, P. Clouva-Molyvda (Athens, GR)

Objective: Previous studies have suggested that catheter-related bloodstream infections (CRBSIs) are associated with lower attributable mortality than other types of BSI. The aim of our study was to compare the impact of primary BSIs (PBSIs) and CRBSIs on length of stay (LOS) and mortality in intensive care unit (ICU) patients.

Patients and Methods: All patients admitted in our 8-bed multidisciplinary ICU were included in the study. Data recorded were: gender, age, admission category (medical, emergent surgical, elective surgical, trauma), Acute Physiology and Health II Evaluation (APACHE II) score at admission in the ICU. All patients were prospectively followed and the occurrence of the first BSI episode in the ICU was recorded. Length of stay (LOS) in the ICU, total number of BSI episodes in the ICU and ICU outcome were recorded. Primary BSI (PBSI) and catheter-related BSI (CRBSI) episodes defined according to standard criteria were analysed. Attributable mortality for PBSI and CRBSI was estimated and further investigated with logistic regression models adjusted for potential confounders. Statistical significance level was set at $p < 0.05$.

Results: Three hundred eighty-four consecutive patients (273 males and 111 females) were included in the study. Age (mean±SD) was 52.9±19.4 years, APACHE II score 18.2±6.4, LOS [median (interquartile range): 16 (9–32) days. In 76 patients (19.8%) the first BSI episode was PBSI and in 41 (10.7%) CRBSI. Overall mortality was 16.4%. Mortality in patients without BSI was 12.0%, in patients with PBSI 27.6% (attributable mortality 15.6%, $p = 0.001$) and in patients with CRBSI 19.5% (attributable mortality 7.5%, $p = 0.189$). LOS was significantly shorter in patients without BSI compared with either PBSI or CRBSI group (14.6±11.0 days vs. 39.0±26.4 days in the PBSI group and 39.8±20.2 days in the CRBSI group, $p < 0.001$). In a logistic regression model adjusted for age, gender, APACHE II score, admission category and total number of BSI episodes in the ICU, PBSI was significantly associated with increased probability of death in the ICU compared with patients without BSI (odds ratio=3.4, 95% confidence interval 1.2–10.7, $p = 0.033$) while CRBSI had no significant effect on mortality.

Conclusions: In our patient sample, PBSI increased 3.4-fold the probability of death in the ICU compared with patients without BSI. The estimated attributable mortality for PBSI was 15.6%. CRBSI did not significantly influence mortality.

P1090 The association between mucosal colonisation with opportunistic pathogens and bloodstream infections in the two neonatal intensive care units in Estonia

Ü. Parm, E. Sepp, T. Metsavaht, M. Ilmoja, K. Pruunsild, L. Maipuu, S. Kõljalg, E. Makoid, I. Lutsar (Tartu, EE)

Objective We aimed to study mucosal colonisation of neonates with potentially pathogenic microorganisms in order to find out whether and how this is associated with blood stream infections (BSI).

Methods All newborns admitted to both Estonian NICUs within first 72 h of life and needing empiric antibacterial therapy (ampicillin or penicillin in combination with gentamicin) for early onset neonatal sepsis were prospectively enrolled. The nasopharyngeal and rectal swabs were collected on admission and thereafter twice weekly until D60 or discharge. Samples were plated on blood, McConkey and Saboraud agar. Blood cultures were drawn when clinically indicated. The final identification of species was conducted with BACTEC 9240, VITEK 2 and API 20E systems. MRSA was identified by PCR for nuc and mecA genes. The genetic relatedness between mucosal and bacteraemic strains of MRSA and *K. pneumoniae* was analysed by pulsed fieled gel electrophoresis (PFGE).

Results A total of 200 pt (100 with BW <1500g; median NICU stay 6.8 days) were enrolled from Aug 2006 until July 2007. The most common colonising Gram-negative microorganisms were *K. pneumoniae* (23%), *E. coli* (15%), E.cloaceae (15%), *K. oxytoca* (14%) & *A. baumannii* (13%) with the median documented duration of colonisation of 8 days for *Klebsiella* spp. and 5 days for the remaining organisms. Of 54 BSI infections 45 were nosocomial origin (58% caused by G-positive, 40% by G-negative and 2% by *Candida* spp.). The risk of BSI was greater during colonisation by G-negative than by G-positive bacteria (15/21 vs 13/31, respectively [OR 3.5; 95% CI 1.1–11.3]). The rate of infection per 100 days of colonisation was the highest for MRSA (4.6) followed by 1.4; 1.2; 0.9; 0.7; & 0.7 for *A. baumannii*, *E. cloacae*, *E. coli*, *K. pneumoniae* & *Serratia* spp., respectively. The lowest rate of 0.2 was observed for *K. oxytoca*. During the study in each unit one outbreak of nosocomial infections caused by K.pneumonia and MRSA, respectively, was seen. Increased rate of mucosal colonisation preceded both outbreaks. A molecular typing of mucosal and BSI isolates of *K. pneumoniae* and MRSA revealed a similar PFGE pattern.

Conclusion In NICU mucosal colonisation by MRSA and to lesser extent by *A. baumannii* and E.cloaceae carries a significant risk for BSI. Isolation of newborns colonised by microbes with the highest risk of subsequent BSI, should be implemented to avoid cross-colonisation by healthcare workers and thus prevent BSI.

P1091 Bloodstream infections among newborns in intensive care unit in a country network in Bogota, Colombia, 2001–2007

I.F. Corrales, J.A. Cortes, A.L. Leal, G. Buitrago, J.S. Castillo, C.A. Alvarez (Bogota, CO)

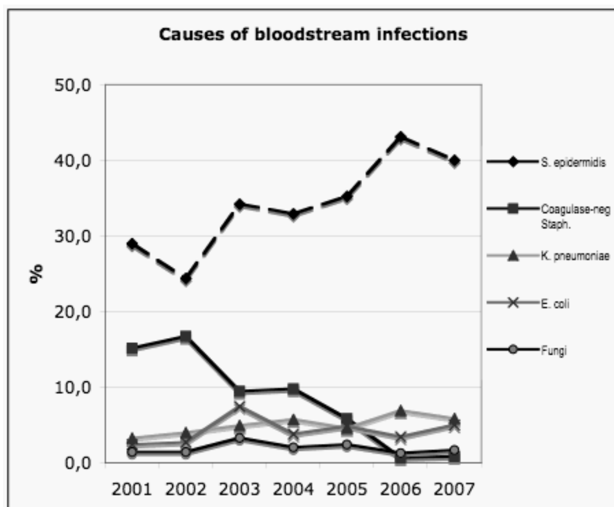
Background: Bloodstream infections are common among patients in the neonatal intensive care unit (NICU). Here we show the frequency of the microroganisms found in the blood of patients in the NICU belonging to a national network in Colombia.

Methods: A country network with 27 public and private tertiary hospitals from 3 cities was stablished. Laboratory information was transferred monthly to a central data base and compiled by the use of Whonet software (WHO, ver 5.4). Bloodstream infections were selected from those patients in the NICU.

Results: Between 2001 and 2007 (june), a yearly average of 689 bloodstream infections were detected among patients in the NICU. 60% to 70% of the isolates were Gram-positive, while near 30% were Gram-negative bacilli. In the figure, the annual percentage of the microorganisms more commonly isolated is shown. Of interest, 84% of the coagulase negative Staphylococci (CNS) were resistant to oxacillin and between 6.9% and 10.8% of *E. coli* isolates had a phenotype that suggested the presence of extended spectrum β-lactamases (ESBL). Such

phenotype was more frequently found in *K. pneumoniae* (41.1% to 51.1%). *Candida albicans* was the most frequently found yeast.

Discusion: Although oxacillin-resistant CNS predominated among bloodstream isolates, a high prevalence of Gram-negative bacilli was found, with a frequent expresion of ESBL. Fungal infections are not uncommon. Higher effords in infection control and antibiotic use should be made in order to diminished the number of resistant infections in high risk neonates.



P1092 Maternal and neonatal bloodstream infections: data from the Finnish Hospital Infection Program, 1999–2006

E. Sarvikivi, O. Lyytikäinen on behalf of the Hospital Infection Surveillance Team, Finnish Hospital Infection Program (SIRO), National Public Health Institute (KTL), Helsinki, Finland

Objectives: Maternal microbial flora may be a source for both maternal and newborn peripartum infection. The aim of this study was to evaluate the epidemiologic features and distribution of the causative pathogens of healthcare-associated bloodstream infections (BSIs) in women who were admitted for obstetric care and in neonates in Finnish hospitals during 1999–2006.

Methods: A prospective laboratory-based surveillance was performed in 9 Finnish acute care hospitals that participated in the Finnish Hospital Infection Program, including three tertiary care centres. Women in labour and infants with ages not more than 28 days were included. Infection-control nurses in each hospital regularly reviewed the laboratory database for positive blood culture results. Clinical information and microbiological data were recorded on a standardised case-record form. CDC definitions for nosocomial BSIs were utilised, both primary and secondary BSIs were included. We focused on ‘early-onset’ neonatal BSIs, referring to an infection with a positive blood-culture during the first 6 days of life.

Results: The study included 175 445 deliveries, of which 30 178 (17%) caesarean sections, and 177 987 live births. We identified 118 maternal peripartum BSIs (rate, 0.7 BSIs/1000 deliveries; range by year, 0.3–1.5/1000 deliveries), of which 67 (57%) occurred after a caesarean section, and 766 neonatal BSIs (rate, 4.4 BSIs/1000 live births), 288 (38%) of which were early-onset BSIs (rate, 1.6 BSIs/1000 live births; range by year, 1.1–2.4/1000 live births). The main causative pathogen of both maternal and neonatal early-onset BSIs was *Streptococcus agalactiae* (GBS) (Table). Of the infants with early-onset BSIs, 116 (40%) received intensive care and 16 (6%) died within a week after the positive blood culture; 7 (44%) of those had GBS disease. One of the mothers received intensive care, none of them died.

Conclusions: Maternal peripartum BSIs were rare and no fatal cases were detected. Neonatal early-onset infections were more common and led often to need of intensive care and even to death. Peripartum infections due to GBS, which was the most common pathogen, may be reduced by national prevention guidelines. Such guidelines were released in 2006 in Finland; future surveillance will show the impact of these guidelines.

Table: Distribution of causative pathogens in maternal and neonatal healthcare-associated bloodstream infections (BSIs) in Finland during 1999–2006

Maternal BSIs (N = 118)		Early-onset neonatal BSIs (N = 288)	
Streptococcus agalactiae	21%	*Streptococcus agalactiae*	33%
Staphylococcus aureus	14%	Coagulase-negative staphylococci	31%
Coagulase-negative staphylococci	11%	*Staphylococcus aureus*	11%
Streptococcus pyogenes	10%	*Escherichia coli*	6%
Viridans streptococci	9%	Enterococci	3%
Eschericia coli	7%		
Enterococci	7%		
Others	22%	Others	16%
Polymicrobial	3%	Polymicrobial	5%

P1093 *Pseudomonas aeruginosa* bloodstream infections: a 6-year retrospective review in a university hospital

C. Meuris, C. Laurent, B. Delaere, Y. Glupczynski (Liège, Yvoir, BE)

Objectives: *P. aeruginosa* bacteraemia (PAB) is a serious infection associated with a high mortality. Severity of underlying diseases, origins of infection, antimicrobial resistance and inadequacy of antimicrobial therapy have all been associated with an excess mortality rate. The objective of this study was to evaluate the epidemiology and the risk factors of PAB on the mortality rates among patients admitted to a 380-bed university hospital.

Methods: Retrospective cohort study of all patients admitted between 01/00 and 12/06 with a clinically significant PAB (at least one positive blood culture, excluding polymicrobic episodes of PAB). All medical charts were reviewed by means of a computer-based system. Variables studied were: demographic data, comorbidities (solid or haematological cancers, chronic lung, cardiac or liver diseases, solid organ transplant), immunosuppressive therapy, hospital events (nosocomial acquisition, admission to ICU, major surgical procedures), appropriateness of empirical antimicrobial therapy, mortality at day 7 and 30.

Results: 81 cases, 51 males (63%). Mean age: 64 yrs. Mean incidence of PAB: 3.9 per 100 bacteraemia episodes; 69% of PAB nosocomially-acquired. Underlying illnesses: 32% haematological cancers; 68% non haematological group (solid cancers 16%, COPD 11%, pulmonary grafts 7%, immunosuppressive therapy 16%), invasive diagnostic procedures 60%. Sources of PAB: respiratory 35%, primary 26%, urinary 15%. Number patients with appropriate empiric therapy 64% (100% with appropriate adjusted therapy). Crude mortality rate associated with PAB 31%; Attributable mortality at day 30 was 21% (18% at day 7); no significant difference in attributable mortality between patients with haematological illnesses (19%) and those with other comorbidities (22%); No differences in mortality rate according to the adequacy or inappropriateness of empirical antimicrobial therapy (20% vs 24%) but 2 out of 3 haematological patients with inadequate initial treatment died from their PAB.

Conclusions: the incidence of PAB has remained stable over 6 years. Two third of the episodes were of nosocomial origin. Haematological diseases, solid cancers and invasive procedures were the most common underlying diseases. Attributable mortality rate at day 30 was 21% and was not influenced by the type of underlying illnesses nor by the appropriateness of initial empiric therapy except in neutropenic patients with haematological cancers.

P1094 Analysis of risk factors for central venous catheter insertion site and catheter tip colonisation and for CVC-associated bloodstream infection in a randomised clinical trial

D. Luft, M. Dettenkofer, C. Wilson, A. Gratwohl, C. Schmoor, D. Heim, H. Bertz, A.F. Widmer (Freiburg, DE; Basel, CH)

Objective: To identify risk factors for skin colonisation prior to central venous catheter (CVC) placement and within 10 days after CVC insertion, for CVC-tip colonisation and for CVC-associated bloodstream infection (BSI).

Methods: As part of a randomised clinical trial, patients in the haematology units of the university hospitals Freiburg, Germany, and Basel, Switzerland and one cardiothoracic surgery unit (Basel) were enrolled after informed consent. Quantitative skin cultures were obtained from the insertion site prior to CVC placement and at regular intervals after CVC insertion. Cultures from the CVC tip on removal were undertaken (roll plate technique). In addition, data were collected on infection signs, therapy, nosocomial infections (according to CDC-criteria). The statistical analysis was performed using linear and logistic regression models.

Results: Four hundred patients (219 haematology, 181 surgery) with inserted CVC were enrolled in the trial (2002–05). Age >65 y and male gender were independent risk factors for skin colonisation prior to CVC placement in all patients and within the subgroup of surgical patients. Independent risk factors for skin colonisation within 10 days after CVC placement in all patients were: (i) colonisation prior to CVC placement (baseline colonisation), (ii) surgical patient, and (iii) male gender. Baseline colonisation of the skin at the insertion site was a strong predictor of CVC tip colonisation ($\geqslant$15 CFU). The underlying disease – haematological malignancy – was the strongest risk factor for CVC-related BSI.

Conclusions: The level of skin colonisation prior to catheter insertion predicts catheter colonisation and possibly subsequent infection. Elderly and male patients are at particular risk for colonisation of the skin and may be a target population for special precautions with meticulous care of the insertion site before and during catheterisation.

P1095 Needleless positive-pressure mechanical valve connectors: are they safe?

V. Cossey, M.J. Thelissen, G.A. Goossens, M. Stas, A. Schuermans (Leuven, BE)

Objectives: To determine whether the introduction of a needleless positive-pressure mechanical valve connector in adult and paediatric hematology-oncology units influenced the rate of catheter-related bloodstream infections (BSI) and the type of causative micro-organisms.

Methods: A mechanical valve (MV) connector system (CLC2000®, ICU Medical) was introduced in November 2005 and replaced miscellanous conventional open systems (COS) with a standard Luer-Lock removable cap. The main objective of this change was to reduce the use of heparin flushes in long-term tunnelled catheters (Hickman®, CR Bard).

The retrospective analysis included all patients with new Hickman catheters, inserted during two different study periods. The catheter-related BSI rate was observed during 6 months for each system and reported as number of BSI per 1000 catheterdays. The results with COS (January through June 2005) were compared with a similar period with MV-use (September 2006 through February 2007). Microbiological characteristics of bacteraemias occurring during each period were also compared. The hospital policy for care of Hickman catheters did not change over both study periods.

Results: During the COS-period, 39 Hickman catheters were inserted in 15 children and 24 adults with a total dwell time of 1544 and 1899 catheter days respectively. During the MV-period 60 Hickman catheters were placed in 13 children and 47 adults with a total dwell time of 1181 and 3223 catheterdays respectively.

Both in the paediatric and adult population, the rate of catheter-related BSI during the MV period was significantly higher than during the COS-period: resp. 11 vs 1.29 infections per 1000 catheterdays (p =.009) and 12.4 vs 6.32 infections per 1000 catheterdays (p = 0.019).

During the MV-period, the percentage of polymicrobial BSIs increased from 0 to 84.6% in children and from 8.3% to 21% in adult patients.

Conclusion: A significant increase in the rate of BSI was found among hematology and oncology patients with newly inserted Hickman catheters concomitantly with a change from a conventional open system to a mechanical valve connector, despite additional educational sessions regarding proper use of the device. The risk and type of BSI are clearly associated with the catheter cap design which promotes microbial contamination. The observed effects are more pronounced in children.

P1096 Late port-a-cath infection with *Enterobacter amnigenus* – An example of Gram-negative port-a-cath infection

W. Lepère, M. Recher, M. Rothen (Bruderholz, Biel, CH)

Objectives: To demonstrate the microbiology of infections of totally implantable venous access devices with emphasis on the importance of Gram-negative bacteria.

Methods: Case report and search of infectious disease charts

Results: We report a case of sepsis with *Enterobacter amnigenus* as a consequence of a totally implantable venous access device infection caused by contaminated saline solution. The indication for implantation of the port-a-cath system had been antibiotic treatment of diabetes-associated osteomyelitis of the foot which had been completed two years before onset of the actual disease. Explantation of the port-a-cath system together with adequate antibiotic treatment rapidly resolved the infection. *Enterobacter amnigenus* is a facultative Gram-negative pathogen associated with soil and water and displays a high percentage of natural antibiotic resistance. *Enterobacter amnigenus* infections have been associated with tap water, cardioplegia ice, thermometers, milk formulas and saline, albumine or heparine infusions. Port-a-cath infections with *E. amnigenus* have not been reported so far.

In a search of the charts of infectious disease consultations during the previous 5 years, 10 port-a-cath infections were identified, of which Gram-negative bacteria accounted for 60%. Gram-negative rods involved were *Enterobacter cloacae* (4), *Klebsiella pneumoniae* (2), *Pseudomonas aeruginosa* (1), *Enterobacter amnigenus* (1) and *Alcaligenes* spp. (1). 3 infections were polymicrobial. Only in 4 cases (40%), typical Gram-positive skin bacteria were identified in pure culture (*Staphylococcus aureus* (3), coagulase-negative streptococci (1)). Treatment of Gram-negative infections always required explantation of the intravascular device.

Conclusion: In conclusion it is crucial to re-evaluate the need for implantable venous access devices once the system is not used for therapy anymore. Furthermore, this case underlines that beside commonly isolated skin bacteria such as streptococcus and staphylococcus species, implantable intravascular catheter infections may also be caused by biofilm-producing Gram-negative bacteria, which should be considered in the empiric choice of antibiotics.

P1097 Under-reporting of occupational blood and infectious fluid exposure in a teaching hospital

M. Pirs, M. Poljak, K. Seme, M. Maticic (Ljubljana, SI)

Background and Objectives: Occupational blood and infectious fluid exposure (OBE) poses a risk to healthcare workers (HCW). Implementation of safety precautions is crucial in preventing the transmission of hepatitis B virus (HBV), hepatitis C virus (HCV), and human immunodeficiency virus (HIV) in healthcare settings. Other key factors are HBV immunisation and appropriate post-exposure management.

The objective of the present study was to determine the proportion of HCW experiencing OBE, post-exposure managing and the proportion of vaccinated HCW in the largest tertiary and teaching hospital in Slovenia. The knowledge of HCW's hepatitis B surface antibody (anti-HBs) status was also assessed.

Methods: 251 HCW from surgical and non-surgical wards and laboratories completed a confidential questionnaire. All categories of HCW were assessed (doctors, nurses, laboratory workers and support personnel).
Results: 124 HCW (49.4%) experienced at least one OBE and only 63 of them (50.8%) reported the incident. HBV, HCV and HIV serology was performed in 44 cases for HCW (69.8%) and in 47 cases for the index patient (74.6%). Our personal observations as well as several studies showed that the most common reasons for non-reporting the OBE are the belief that the patient involved was not infected with HIV or HCV and that the wound was adequately disinfected. Significant amount of time and paperwork involved in reporting the incident are also a factor. Another important reason is the fear of being judged as well as the anxiety they would suffer while waiting for the test results. The data was further analysed according to category of HCW as shown in table 1.

Table 1. The analysis of the results of confidential questionnaire among HCW according to job category.

	all HCW No. (%)	physicians No. (%)	registered nurses No. (%)	nurses No. (%)	support personnel No. (%)	laboratory workers No. (%)
No.	251	51	38	88	8	66
HBV vaccination	229 (91.2)	49 (96.1)	37 (97.4)	82 (92.3)	3 (37.5)	58 (89.2)
anti-HBs titer following vaccination	106 (46.3)	22 (44.9)	23 (62.2)	22 (26.8)	3 (100.0)	36 (60.0)
Latest anti-HBs titer	227	49	36	80	6	56
0 IU/mL (non-responder)	15 (6.6)	2 (4.1)	1 (2.8)	5 (6.3)	0 (0.0)	7 (12.5)
>10 IU/mL	73 (31.9)	23 (46.9)	16 (44.4)	7 (8.8)	0 (0.0)	27 (48.2)
unknown	83 (36.2)	18 (36.7)	14 (38.9)	42 (52.5)	1 (16.7)	8 (14.3)
never determined	56 (24.5)	6 (12.2)	5 (13.9)	26 (32.5)	5 (83.3)	14 (25.0)
OBE	124 (49.4)	34 (66.7)	28 (73.7)	44 (50.0)	2 (25.0)	16 (24.2)
Reporting of OBE	63 (50.8)	15 (44.1)	17 (60.7)	22 (50.0)	1 (50.0)	8 (50.0)
HBV, HCV and HIV screening of HCW	44 (69.8)	11 (73.3)	12 (70.6)	13 (59.1)	1 (100.0)	7 (87.5)
HBV, HCV and HIV screening of index patient	47 (74.6)	13 (86.7)	15 (88.2)	12 (54.5)	1 (100.0)	6 (75.0)
Anti-HBs titer following reported OBE:	54 (85.7)	12 (80.0)	15 (88.2)	19 (86.4)	1 (100.0)	7 (87.5)
0 IU/mL (non-responder)	5 (7.9)	1 (7.1)	2 (12.5)	0 (0.0)	0 (0.0)	2 (25.0)
>10 IU/mL	28 (44.4)	9 (64.3)	8 (50.0)	8 (38.1)	0 (0.0)	3 (37.5)
unknown	27 (42.9)	4 (28.6)	6 (37.5)	13 (61.9)	1 (100.0)	3 (37.5)

HCW – healthcare workers. OBE – occupationa1 blood and infectious fluid exposure; HBV hepatitis B virus. HCV – hepatitis C virus. HIV – human immunodeficiency virus; anti-HBS serum level of hepatitis B surface antibody.

While the majority of HCW received HBV immunisation (91.2%), the serum concentration of anti-HBs following immunisation was assessed in 106 (46.3%) HCW only. 15 (6.6%) HCW were non-responders and 73 (31.9%) reported adequate serum levels. Surprisingly, over one third of HCW (36.2%) did not know their serum levels of anti-HBs, while for 56 (24.5%) their response to immunisation was never confirmed.
Conclusion: The rate of OBE in this pilot study and inadequate post-exposure measures are disturbing. Our data has shown that better educational programs are needed to increase awareness about the risk and prevention of OBE among the HCW. HCW should be encouraged to undergo testing to determine adequate response to HBV vaccination and most importantly to improve the compliance with the recommended measures following OBE.

P1098 Healthcare workers' exposure to blood-borne pathogens in Lebanon

U. Musharrafieh, A. Bizri, N. Nassar, A. Rahi, A. Shoukair, R. Doudakian, G. Hamadeh (Beirut, LB)

Objectives: Study the pattern of occupational exposure to blood and body fluids (BBFs) at a tertiary care hospital in Lebanon for 17 years. This is the first study to provide baseline data aiming to introduce the suitable interventions.
Methods: This study retrospectively reports a 17 year experience (1985–2001) of on-going surveillance of HCW exposure to BBFs at a 420 bed academic tertiary care hospital. Exposures were defined as any eye, mouth, or other mucous membrane, non-intact skin, or parenteral contact with blood, or other potentially infectious body fluid. The endpoints were the annual number, nature, and cause of accidents, as well as the HCW's status, injury tool, site, and source.
Results: 1590 BBF exposure-related accidents were reported to the Infection Control Office. The trend showed a decrease in these exposures over the years with an average ±SE of 96±8.6 incidents per year (figure). In the last 6 years, the average rate of BBF exposures was 0.57 per 100 admissions per year (average of needle stick injuries alone was 0.46 per 100 admissions). Needle sticks accounted for 75% of the injuries, sharp objects for 10%, splash and spill for 3%, and in 12% it was not clearly specified. The highest occurrence of these exposures was on the ward (35%) followed by the operating room (17%) and intensive care units (15%). The reason for the incident, when stated, was attributed to a procedural intervention (29%), improper disposal of sharps (18%), to recapping (11%), and to other causes (5%). The patient or source of incident was known in 64% of cases. For studying rates of exposure among the different occupational categories, the year 2001 was taken as an example. 13% of house officers, 9% of medical students, 8% of attending physicians, 5% of nurses, 4% of housekeeping, 4% of technicians, and 2% of auxiliary services employees had a BBF exposure during that year.

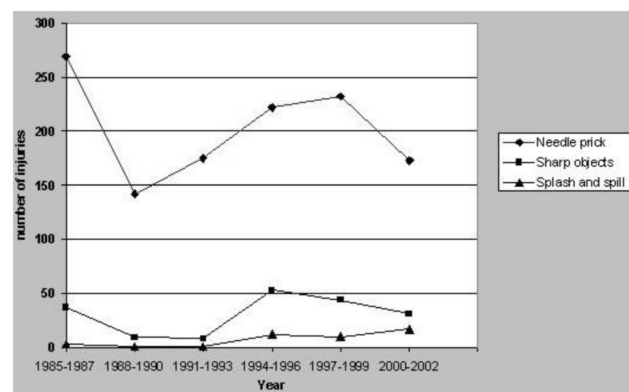


Figure 1. Incidence of blood and body fluids exposure over the years by type.

Conclusion: The current study showed that exposure of HCWs to BBPs remains a problem. This can be projected to other hospitals in the country and raises the need to implement infection control standards as part of a complete system where the culture of safety becomes an integral part of the organisation. Prospective studies are needed on a yearly basis to identify high risk groups and develop focused interventions.

P1099 Underreporting of accidental blood exposure in Belgian hospitals

E. Leens, C. Suetens on behalf of the Belgium National Steering Group of Accidental Blood Exposure

Objectives: In order to estimate the percentage of accidental blood exposures (ABE) not reported to the occupational health department in Belgian hospitals, a national underreporting study was carried out.
Methods: In May 2006, the Scientific Institute of Public Health invited 55 hospitals participating to the national surveillance of ABE (EPINet) to the study. Twenty percent of the healthcare workers (HCW) filled out a questionnaire anonymously during the annual consultation of occupational health (OH). They were asked how many percutaneous injuries (PI) or blood or body fluid exposures (BFE) occurred during the last month and the last year, and if so for how many ABE a registration formular (EPINet or OH insurance) was filled out.
Results: Till 28 February 2007, a total of 3311 questionnaires from 25 hospitals was received. For the recall period of 1 month 103 PI occurred in 78 HCW, of which 52 PI were registered by 38 HCW (underreporting of 49.5%, Table 1). BFE were more frequent in 1 month, but were much less registered: 165 HCW mentioned 452 BFE in the study, but only 3 cases (by 3 HCW) were declared to the surveillance or OH insurance system (99.3%). For the recall period of 1 year the percentage of non-reported injuries was 45.2% of the PI and 96.4% of the BFE.

Table 1: Percentage not reported ABE in Belgian hospitals, 2006

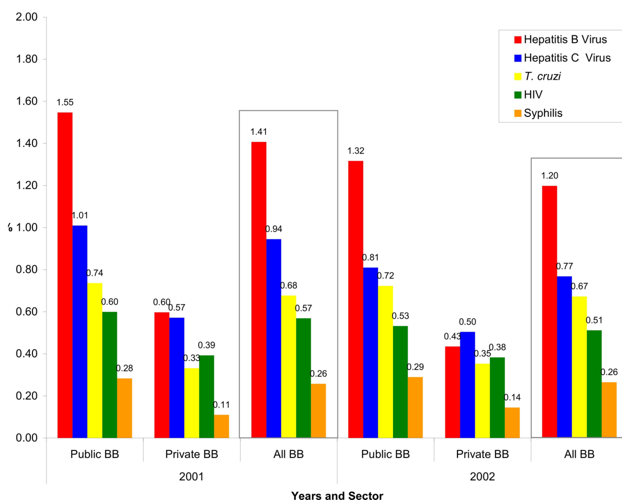
	% not reported (95% CI)	
	last month	last year
PI	49.5% (39.5–59.5%)	45.2% (40.8–49.6%)
BFE	99.3% (98.1–99.9%)	96.4% (95.1–97.4%)

Conclusion: Results show that half of the PI was not declared by the HCW. The underreporting rate in Belgian hospitals is similar to average rates found in literature. The high underreporting rate for BFE was possibly related to a misinterpretation of the definition. Based on the results of this study and the PI rates of the national surveillance, the annual number of PI in Belgian hospitals could be estimated at approximately 10800 PI.

P1100 Seroprevalence of blood-borne infections among blood donors in Venezuela, 2001–2002

J. Benitez, A. Rodriguez-Morales, M. Arria (Maracay, Trujillo, Caracas, VE)

Objectives: From the data collected at the Ministry of Health from whole nation public and private blood banks (BB) find out the proportion of blood units discarded for being seropositive HBV, HCV, HIV, syphilis and *Trypanosoma cruzi*, and the seroprevalence of these infections among their donors.
Methods: ELISA serological testing was done with 715,393 donors seen at 535 blood banks between 2001 and 2002. Samples that were repeat reactive (RR) with the ELISA underwent supplementary Western blot (WB) testing.
Results: Of the 715,393 blood banks donors, 9,294 of them (1.3%) were positive for syphilis (VDRL), 6,107 (0.85%) for HBV (anti-HBc), 4,825 (0.67%) for *T. cruzi*, 3,859 (0.54%) for HCV and 1,870 (0.26%) for HIV. In the Figure a summary of the seroprevalence of these infections, among public and private blood banks, per year, is presented.



Conclusions: Although syphilis or *Treponema pallidum* infection was the most important blood-borne disease found in this study, the seroprevalence found is lower than others reported in other countries in the region (e.g. Goiânia, Brazil, 1989, 4.1%). For HBV and HCV, the seroprevalence estimates were also similar than those found in other countries in the region (such as Río de Janeiro, Brazil, where in 2005 the anti-HBc was 2.05% and 0.79% in 2004 for HCV), indicating high rates of infection by HBV and HCV and a persistent risk of HBV and HCV transmission by transfusion. For Chagas disease is also lower than others reported in other countries in the region (e.g. Goiânia, Brazil, 1989, 3.3%). Finally for HIV the found seroprevalence is similar to that reported in Mexico (Irapuato, Mexico, 2003, 0.24%). But as seen herein, those seroprevalences are regional, and our report is nationwide. Further epidemiological research is expected. [Figure. Seroprevalence of Blood-borne Infections among Blood Donors in Public and Private settings in Venezuela, 2001–2002]

Infection control and nosocomial infections

P1101 Skin care and use of colouring- and perfume-free products for hand hygiene: important foci for hand hygiene promotion

A. Conrad, I. Poser, S. Wenzler-Röttele, A. Pfister-Wartha, M. Dettenkofer (Freiburg, DE)

Objective: Hand disinfection with an alcoholic hand rub is the most effective measure for preventing nosocomial infections. However, frequent use of hand hygiene products may cause skin irritation, which, in turn, results in poor hand hygiene compliance. Additionally, many products contain colouring and perfumes which hold a certain risk of sensitisation, although they do not contribute to efficacy. The objective was to improve hand hygiene by promotion of skin care and introduction of colouring and perfume-free products for hand hygiene.
Methods: A campaign to improve hand hygiene at the University Medical Center Freiburg, Germany, was initiated along with the introduction on 11 intensive care units and hematology wards of a colouring and perfume-free product line (disinfectant and soap). The intervention was accompanied by 15 min training sessions on hand hygiene indications, technique and skin care. Before and after a 6-week intervention phase, opinion on hand hygiene and acceptance of products were evaluated using structured questionnaires.
Results: Of a total of over 1200 questionnaires distributed 54% (of 660) were completed before and 41% (of 611) after the intervention (by nurses and by physicians). Hand hygiene was judged to be of high relevance to patient safety by 76% of the respondents before and by 85% after the intervention. Before the intervention, 36% had no preference for any hand disinfectant, and used various products according to availability. However, after the intervention 41% preferred the colouring and perfume-free alternatives. This figure was dependent on gender since almost 50% of women preferred the test products compared to less than 30% of the men. The colouring and perfume-free products were generally tolerated as well as conventional preparations. Only 3% of the respondents complained about malodour of the test preparations. The most frequent complaint associated with hand hygiene preparations in general was dryness of the skin (over 70%). Healthcare workers' use of skin care rose from 52% to 64%.
Conclusions: Skin care and use of colouring and perfume-free products are important foci of hand hygiene promotion. Taking into account that staff tends to prefer products they know, this project successfully introduced a colouring and perfume free-product line which was well tolerated. Since colouring and perfume are dispensable, in future, only colouring and perfume-free hand hygiene products should be used in daily routine.

P1102 Effectiveness of hand-cleansing agents for removing meticillin-resistant *Staphylococcus aureus* from contaminated skin

Z. Muszynski (Poznan, PL)

Objectives: The effectiveness of hand-cleansing agents in removing a hospital strain of meticillin-resistant *Staphylococcus aureus* from artificially contaminated hands of ten volunteers was studied.
Methods: The products used were plain liquid soap, ethyl alcohol 70% (by weight), 10% povidone-iodine liquid soap (PVP-I), and 4% chlorhexidine gluconate detergent in water. The experiments were performed using a Latin square statistical design, with two 5 x 4 randomised blocks. The removal rates of *S. aureus* cells from contaminated fingertips were estimated by analysis of variance, the response variable being the logl0, reduction factor (RF), ie, logl0 of the initial counts minus logl0 of the final counts. In the first and second

blocks, the fingertips of the volunteers were contaminated in mean with 3.95 logl0 colony-forming units (CFU) light-contamination hand and 7.24 logl0 CFU heavy-contamination hand, respectively.

Results: In the first block, there were significant diferences between treatments (P < 0.05). The 10% PVP-I (RF, 3.96) and 70% ethyl alcohol (RF, 3.95) had significantly higher removal rates than plain liquid soap (RF, 2.44) and 4% chlorhexidine (RF, 2.98). In the second block, 10% PVP-I (RF, 4.55) and 70% ethyl alcohol (RF, 3.80) also were significantly more effective than plain liquid soap (RF, 1.95) and 4% chlorhexidine (RF, 2.24; P < 0.05). Plain liquid soap was significantly more effective than 4% chlorhexidine detergent.

Conclusions: The results suggest that 10% PVP-I and 70% ethyl alcohol may be the most effective hand-cleansing agents for removing meticillin-resistant *S. aureus* strain from either lightly or heavily contaminated hands.

P1103 Hand hygiene after toilet visits

D. van der Vegt, A. Voss (Nijmegen, NL)

Introduction: Compliance with hand hygiene in the healthcare setting, is generally low (on average 40%), despite the fact that good hand hygiene still is one of the most important measures to prevent nosocomial infections. Since the main indications for hand hygiene differ between healthcare and non-healthcare settings no comparison has been done.

Objective: Aim of the present study was to investigate the degree of compliance with hand hygiene after toilet visits in and outside the healthcare setting.

Methods: We observed different group of healthcare providers (hospital/laboratory personnel and participants of ECCMID 2007), and users of public lavatories along motorways with regard to their compliance with hand washing after toilet visits

Results: Compliance with hand hygiene after toilet visits was, 46%, 84% and 75%, respectively. Obviously, healthcare workers show a different compliance with hand hygiene in and outside the healthcare setting.

Conclusion: While the comparison of these different groups most certainly is "flawed" and "biased" it is interesting to see, that hand hygiene compliance after toilet visits is the lowest in the healthcare setting, while another group of healthcare-workers (ECCMID participants) had the highest compliance. Possibly, the feeling of a "miasmic" environment (presumed "dirty" public toilets) triggers hand hygiene compliance, whereas the "clean" hospital environment may jam the trigger to do so.

P1104 Engaging more than 300 healthcare facilities from Europe to participate in the testing of the WHO multimodal hand hygiene improvement strategy

G. Dziekan, J. Storr, B. Allegranzi, A. Leotsakos, C. Engineer, H. Sax, D. Pittet (Geneva, CH)

Healthcare-associated infections (HAI) affect hundreds of millions of people worldwide and are a major global patient safety issue. During healthcare delivery, in most cases pathogens are transmitted by healthcare workers' hands.

Prevention of HAI is the target of the First Global Patient Safety Challenge, "Clean Care is Safer Care", launched in October 2005 by the WHO World Alliance for Patient Safety. WHO "Guidelines on Hand Hygiene in Health Care (Advanced Draft)" have been produced together with a multimodal implementation strategy to improve hand hygiene at the bedside. The strategy is currently being tested at selected hospitals within each of the six WHO regions worldwide to validate the guideline-recommendations.

Objective: To acquire feedback on the feasibility of implementing a multimodal HH improvement strategy in non-selected healthcare facilities across the socioeconomic and cultural range, including highly developed and least developed countries.

Methods: The WHO programme has set up a web-based community platform to allow every HCF in the world to register and participate as a Complementary Test Site. Registered facilities have access to a suite of 40 implementation, training and evaluation tools, including a detailed "Guide to Implementation".

Results: Within the first ten months more than 300 healthcare facilities (hospitals, ambulatory clinics, long-term care facilities) from European countries have registered either as individual healthcare settings or represented by national/sub-national coordinators. Several networks of hospitals have formed as part of national or sub-national campaigns following a pledge by the Ministry of Health to address the growing burden of HAI. In Italy 143 hospitals are engaging in the HH improvement strategy, in Switzerland 116 hospitals, in Spain and Cataluña 22 hospitals are participating. National coordinators have adapted and translated the provided material to implement the multimodal HH improvement strategy to ensure engagement and sustainable effect.

Conclusion: Political awareness and leadership can mass-mobilise healthcare facilities to engage in quality improvement strategies offered at a global level. Coordination at national or sub-national levels is needed to provide a consolidated approach to ensure sustainability.

P1105 Foul places to trigger clean behaviour

B. Wiesman, M. van Schie, A. Voss (Delft, Nijmegen, NL)

Introduction: Compliance with hand hygiene is a continuous problem within healthcare settings. Multimodal interventions are recommended to improve healthcare workers compliance, including those focussing the attention on hand hygiene by visual reminders, such as "speaking walls" (posters).

Objective and Method: We were looking for new and innovative ways of placing reminders for hand hygiene within the hospital setting. Aim of the study was to evaluate the effect of "promotional toilet paper" on hand-rub use in hospital wards. The hand-rub use was measured using dispensers equipped with sensors that allowed wireless transfer of data to a central computer. A software was developed to translate the different dispenser motions into hand-rub use data (NewCompliance®)

Results: Placement of promotional toilet paper significantly increased the hand rub use of healthcare workers. The effect decreased after some time and could be repeated after introduction of a new design.
Conclusion: This study shows that a simple, low cost intervention, namely the placement of toilet paper containing motivational messages, may have a significant impact on the use of hand disinfectants and may therefore become a part of the multimodal interventions to increase hand hygiene compliance. Furthermore, automated data collection of hand rub use can be a useful instrument to evaluate the effect of interventions to increase hand hygiene compliance. As with many interventions, the effect loses its impact over time, but can be boosted by a change of motifs. Obviously, in the case of motivational toilet paper, clean behaviour can be triggered in foul places.

P1106 Wristwatches as potential sources of hospital-acquired infection

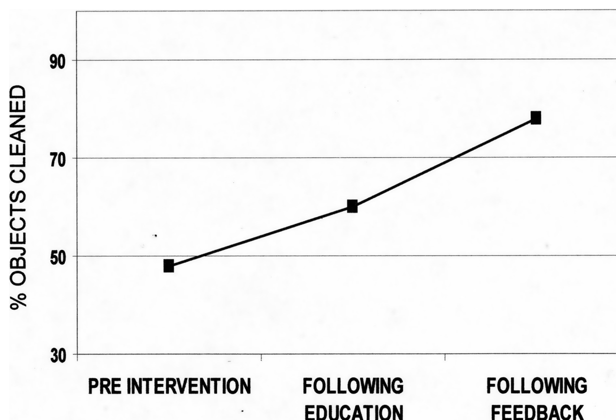
A.R. Jeans, J. Moore, C. Nicol, C. Bates, R.C. Read (Sheffield, UK)

Objectives: To measure the rate of bacterial hand and wrist contamination, particularly by *Staphylococcus aureus*, amongst healthcare workers (HCWs) who wear wristwatches.
Methods: Two consecutive cohort studies of wristwatch wearers and non-wristwatch wearers were conducted amongst samples of HCWs. In the first study (n = 300), wrists were sampled by skin swabs and hands by direct plate inoculation. In the second study (n = 355) this was done after the HCW was asked to remove their watch immediately prior to sampling.
Results: *S. aureus* was found on the hands of 25% of the wristwatch wearers and 22.9% of the non-wristwatch wearers in the first study. Watch wearers had higher counts of bacteria on their wrist ($p < 0.001$), but not on the hands.
In the second study, removal of the watch prior to sampling resulted in increased counts of bacteria on both hands as well as the watch wrist compared with non-watch wearers ($p < 0.001$).
Conclusion: Wristwatch wearers have an excess of bacterial contamination of the wrists. They do not have an excess of hand contamination unless the watch is manipulated.

P1107 Improving patient area disinfection cleaning in 34 acute care hospitals

P. Carling on behalf of the Healthcare Environmental Hygiene Study Group

Objectives: It has become increasingly recognised that microbial contamination of the patient's immediate environment plays a significant role in the transmission of many healthcare associated pathogens. Despite the recent recommendation that hospitals experiencing increased transmission of MDROs "Monitor (i.e., supervise and inspect) cleaning performance to ensure consistent cleaning and disinfection of surfaces in close proximity to the patient and likely to be touched by the patient and healthcare professionals" (CDC –2006; Category 1B), there currently exists no practical means of evaluating and improving the effectiveness of these activities.
Methods: An invisible fluorescent targeting method was used to confidentially evaluate the cleaning of 14 standardised high-touch objects. Rooms were marked following terminal cleaning and re-evaluated after one to two patients had occupied the room and it had been again terminally cleaned.
Results: 1511 rooms and 19,361 objects were evaluated in 34 hospitals ranging in size from 25 to 721 beds. The mean proportion of objects cleaned was 48.5% (95% CI 42.9 to 47.5) prior to educational interventions. While sinks and toilet seats were relatively well cleaned (79.5%), consistently low rates of cleaning were documented for objects at high risk for microbial contamination including bedpan cleaners, toilet area handholds, bathroom and room doorknobs and bathroom light switches (23.3%). Following educational programs and process improvement feedback the cleaning of 448 rooms and 5386 objects were evaluated in the same manner. Overall thoroughness of cleaning improved to 77% (95% CI 78.5% to 89.2%) or 62% from baseline. All hospitals realised significant improvement over pre-intervention results ($P \leqslant 0.0001$).
Conclusion: The use of an objective targeting method in 34 acute care hospitals disclosed substantial opportunities for improving room cleaning/disinfecting activities. Following educational interventions and ongoing performance feedback to the environmental services staff, highly significant enhancement of near-patient environmental cleaning was objectively documented in all hospitals.



P1108 Bactericidal effect of disinfectants on *Chryseobacterium meningosepticum*

M. Ceyhan, E. Kilic, I. Yildirim, M. Ozalp, A.B. Cengiz, A. Bagdat, C. Barin (Ankara, TR)

Three outbreaks caused by *Chryseobacterium meningosepticum* on 5 different wards of a tertiary care paediatric hospital (Hacettepe University, Ankara) with 7 different positive environmental samples were observed between July 2006 through January 2007.Antibiogram typing and ERIC-PCR revealed that all isolates were epidemiologically related. *C. meningosepticum* was isolated from several dry environmental samples(electric button, computer keyboard, phone, door knob, AMBU bag) in addition to an infant formula. Disinfection and cleaning of the environmental surfaces were started in twice daily manner. However, we could not find any precise route of disinfection and type of chemical to use in the literature. This study was planned to evaluate the efficacy of hospital disinfectants against *C. meningosepticum*.
Polyhexanide (Hexanios G+R, France), didecyl dimethylammonium chloride (Surfanios, France), 4% chlorhexidine digluconate (Dermanios scrub chlorhexidine, France), 6.66 g benzalkonium chloride plus 3.33g alkyldimethylammonium chloride (Cleanisept spray, Germany) and solution containing 42 g ethanol, 0.05g didecyl dimethylammonium chloride (Descosept AF, Germany) were tested for bactericidial activity against *C. meningosepticum* isolated from the door-knob according to the principles of EN 1040 standarts. Surviving colonies were enumerated and expressed as colony forming units per milliliter. The reduction rate was calculated as the expression of the disinfectant efficacy according to the following formula $\log_{10}$ reduction = $\log_{10}$ control count – $\log_{10}$ disinfection count. Log_{10} reductions of >5 were taken as an indication of satisfactory bactericidal activity. Susceptibility testing was performed using the quantitative suspension test.
The test results are presented as $\log_{10}$ reduction of the bacteria after 5 and 60 minutes of contact. All studied disinfectants were uniformly bactericidal (effective in producing a >5-log reductions) in 5 and 60 minutes at their in-use concentrations. The efficacy of Hexanios G+R and Surfanios were tested three different concentrations including in-use concentrations, other disinfectants were studied for in-use concentrations only.
The efficacy of surface disinfection and cleaning in reducing microbial loads and their dissemination is one of the critical points to control

outbreakprevent prevention of nosocomial infections. All of the studied disinfectants can be used in cleaning of the environmental surfaces during nosocomial *C. meningosepticum* outbreaks.

P1109 A new experimental model designed to evaluate the antifungal effect of UVC radiation against medical airborne fungi

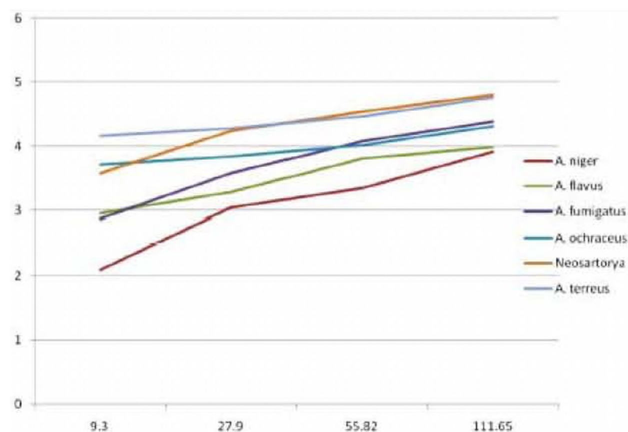
L. Malic, I. Ailincai, M. Mares (Iasi, Bucharest, RO)

Objectives: The aim of this paper is to propose a new and reproducible experimental model designed for evaluation of fungicidal effect of UVC radiations with a wavelength of 254 nm against medical airborne fungi, and its validation.

Methods: We achieved a testing module with a continuous monitoring and setting of work parameters (temperature, humidity, exposure time) and a complex device for generating UVC radiations and measurement of dose which offer the possibility to perform experiments in biological and radiological safety conditions. In order to validate this device, we performed some experiments with six strains of airborne fungi (*Aspergillus niger*, *A. flavus*, *A. fumigatus*, A. ochraceus, *A. terreus* and Neosartorya fischeri). For testing we used fungal spores suspensions in saline solution with 0.05% Tween 80, having a final concentration of 10^6 CFU/ml. From each suspension, 0.1 ml have been plated onto Potatoes Dextrose Agar and after drying, the Petri dishes were exposed to UV radiations in a dark field for various periods of time (final doses: 9.3, 27.9, 55.82 and 111.66 mWs/cm^2). After exposure, the plates were rapidly covered with black paper and transferred to incubation in order to prevent DNA photoreactivation. Each test was done in triplicate. After 72–96 hours of incubation, the intensity of fungicidal effect has been calculated using the Ir (decimal logarithmic reduction index).

Results: The Ir values have a linear increment for all tested strains while the UV doses increase. The arithmetic means of Ir were: 3.16 – *A. niger*, 3.58 – *A. flavus*, 3.89 – *A. fumigatus*, 3.96 – A. ochraceus, 4.29 – N. fischeri, 4.41 – *A. terreus*. The difference of susceptibility for these six species to UVC radiation is not statistical significant ($p \gg 0.05$), but the increase of p values when *A. terreus* is compared with the remaining strains emphasise some minor differences. Also, no significant differences were observed between the three series of experiments ($p > 0.05$) demonstrating the validation of our model as a reproducible one.

Conclusion: We proposed and verified a new experimental model for studying the fungicidal effect of UVC radiations. The tests performed using six strains of spore-forming fungi have proved that our model is a safe, easy to perform and reproducible one. This model may be used for dose evaluation in order to determining the appropriate CFU number reduction for medical airborne fungi in hospitals, pharmaceutical, food and feed industries.



P1110 Point-of-use filters to prevent fungal contamination of hospital water

A. Onken, P. Gaustad, T.G. Abrahamsen, A. Warris (Rud, Oslo, NO; Nijmegen, NL)

Objectives: To investigate whether the installation of point-of-use filters could retain the fungal contamination of the hospital water at the Rikshospitalet, Univ. of Oslo, Norway. Previously, we showed that the hospital water of the paediatric oncology department was contaminated by fungal organisms. Furthermore, hospital water has been suggested as a route for transmission of invasive filamentous fungal infection and preventive measures are needed to protect immunocompromised patients.

Methods: In April 2005 water samples were taken from 10 showers (hot water) and 10 sink taps (cold water) at the paediatric oncology ward, including four BMT units. The samples were collected in sterile glass bottles on three different days in an 8-day period. Then, point-of-use filters (Pall-Corporation®) were installed on the taps and showerheads. Sixty samples were taken from showers and sink taps before installation point-of-use filters, 20 samples were taken with the filters in place. The collected samples were filtered through sterile filters, pore size 0.45 μm. The filters were deposited on Sabouraud glucose agar, incubated for 7 days and examined for fungal species and identified by macroscopic and microscopic characteristics. *Aspergillus* isolates were identified to the species level.

Results: Filamentous fungi were recovered from 97% (58 of 60 samples) of the water samples before installation of the point-of-use filters. *Aspergillus fumigatus* was isolated in 21 of 60 samples (35%).

On average, 2.9 colony forming units (cfu)/ 500 ml of filamentous fungi were recovered, *Aspergillus* sp. 0.7 cfu/ 500 ml, *A. fumigatus* 0.6 cfu/ 500 ml.

After the installation of local filters no moulds were recovered (20 samples), but the filters were rapidly occluded within 1 or 2 days. Electron microscopy showed that the surface of the occluded filters was completely covered with large amounts of particulate colloidal material.

Conclusions: The installation of point-of-use filters retained the fungal contamination of the hospital water completely. Due to a high level of organic material in the water, the filters were blocked after being in use for only 1 or 2 days. Pre-filtration at the inlet of the water into the paediatric oncology department should be carried out to get rid of the organic materials. At present, it is not clear, if this is feasible. Our findings indicate that point-of-use filters might be useful unless the water contains much organic material blocking the filters.

P1111 Healthcare professional preferences in educational strategies against antimicrobial resistance in a developing country

J.S. Castillo, R. Sánchez, G. Buitrago, A.L. Leal, J.A. Cortés, C.A. Álvarez on behalf of GREBO

Background: Infection control strategies are based on behaviour understanding and education. Educational strategies tend to fail due to inability to use adequate methodologies or didactic approaches to healthcare workers. Here we try to find out the educational preferences for healthcare workers in Bogotá, Colombia.

Methods: We perform a cross sectional survey in a 50 hospitals network with 11626 hospital healthcare workers. Estimated sample size was collected with a multi-stage sampling strategy. Interviews were done using a format defined by an expert panel. Preferences were scored in a likert scale. An electronic capture application (Teleform™) was used, all descriptive analysis were carried out in Stata 9.0 (licensed version).

Results: 598 healthcare givers were included. All work shifts were represented. Sample had 33.1% physicians, 41.6% nurses and 25.3% other healthcare givers. 65.7% reported only graduate instruction. Inadequate self reported knowledge was 33.8%, no differences between medical and non medical professionals were not found. Educational activities were a need for therapeutic and preventive areas. How to give information to patients was a second motivation for physicians. Workshops were the most preferred educational activity (Figure 1). The

main argument to choice an strategy were in decreased order the capacity to improve knowledge, availability, no special technology requirements, finantial support, time and effort demanding activities (Figure 2).

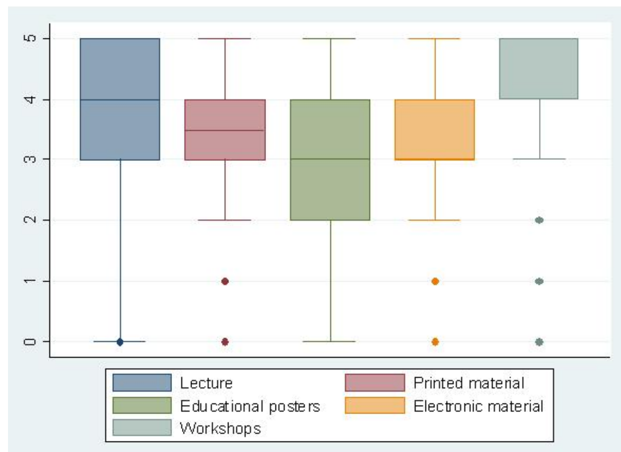


Figure 1. Preferences in educational methodology

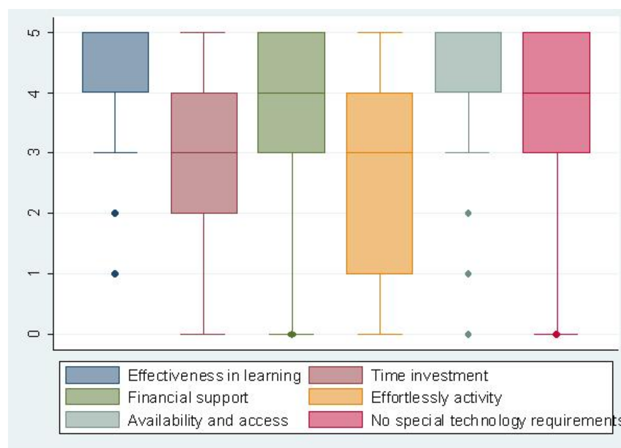

Figure 2. Key features for activity selection

Conclusions: No differences were found in preferences for medical and nonmedical target. Self reported preferences are of great relevance to design an educational intervention to contain antimicrobial resistance. Participatory interventions as workshops are the favorite ones.

P1112 Influence of a hygiene promotion programme in infection control on an intensive care unit

J.F. Murcia-Payá, E. García-Vázquez, A. Melgarejo-Moreno, J. Martínez-Hernández, F.J. Gil-Sánchez, M. Canteras, J. Gómez-Gómez, J. Allegue (Cartagena, Murcia, ES)

Objectives: The inconsistent application of hygiene measures by healthcare workers accounts largely for the epidemic dissemination of nosocomial infections (NI); our aim is to know the prevalence of NI on an Intensive Care Unit (ICU) and to assess the influence of a hygiene promotion programme in the rate of NI.

Patients and Methods: The efficacy of a hygiene promotion programme to prevent NI was assessed in our ICU during 1-year period; initially, a prospective and observational study of NI cases on the ICU during a 6 month period (PI) was done; epidemiological and clinical variables as well as information about risk factors related to NI were assessed. These data were compared to those corresponding to a second prospective and observational study period (PII) during which a health-workers hygiene promotion programme was established. Education of hospital staff was an essential component of the programme aimed to predispose healthcare workers to adopt hand hygiene behaviour (poster campaign and educational meetings and handouts), reinforce and enable the behaviour (provision of an alcohol hand rub beside each patient's bedside). Antibiotic policies and ICU staff were the same during the two periods.

Results: 395 patients were assess during PI and 411 in PII; there were not statistically significant differences on epidemiological or clinical variables during the two periods; there was no difference in risk factors related to NI (underlying conditions, severity at admission, rate of urgent surgeries, invasive techniques, ICU length of stay, mechanical ventilation, etc.). The rate of infection in PI was 26% and 16% in PII ($p < 0.05$). Hand-washing rate was significantly higher in PII than in PI (previous to patient care: 45% and 35% respectively and post patient care: 63% and 51%, respectively)

Conclusion: Patient's features during PI and PII were similar; there was a significant increase in ICU staff hand-hygiene compliance during the educational phase; the incidence rates of NI during the pre-programme period (PI) were significantly higher than during the programme period.

P1113 Peripheral venous cannulation in surgical patients: could we improve?

A. George, S. McKain, K. Shute, K. Swarnkar (Newport, UK)

Aims: More than 90% of all patients admitted to hospital will have a peripheral cannula inserted. Complications associated with this procedure include extravasation, thrombosis and infection. We aimed to investigate both the compliance of peripheral venous cannulae insertion with national guidelines as well as assess the indications, maintenance and complications associated with its use.

Methods: 40 randomly selected surgical patients with a peripheral venous cannula in situ were monitored daily for 8 days or until removal of the cannula. A non-interventional study was undertaken by gathering information on all aspects of care including site, size, use and indications, level of documentation, status of dressings, infection/ thrombosis risk using the VIPS (Visual Infusion Phlebitis Score) as well as cannula changes.

Results: Analysis demonstrated poor compliance with choice of non-dominant hand, cannula size, continuing indications for use. 96% of cannulae had no documentation regarding its insertion, removal or changes. 40% of the inserted cannulae were never used. Compliance of cannulae care and maintenance was poor with most of the cannula dressings becoming contaminated with blood, pus or fluid or the cannulae being inappropriately secured with non-sterile adhesive tape and bandage dressings – inappropriate and contaminated dressings showing a strong association with infection. A high rate of infected cannulae (17%) and a non-compliance with best practice for cannulae removal was seen even when the VIPS score was 2 or more (indicating active thrombophlebitis) with a significant group being left in and used even in the presence of active infection. Most cannulae were left in-situ for 48 or more hours after its use had stopped with a significant minority being left in for more than 120 hours.

Discussion: This study shows that though definite protocols exist for the use, maintenance and removal of peripheral cannulae, they tend to be eclipsed and sidelined. The insertion of these small peripheral intravenous devices poses the potential of becoming a major source of infection if their use and maintaince is not monitored. An overall improvement in the awareness of peripheral intravenous cannulae care, use and documentation is essential to ensure best practice in surgical patients.

P1114 Simple procedures to reduce *Staphylococcus epidermidis* adhesion to indwelling medical devices

C. Sousa, P. Teixeira, R. Oliveira (Braga, PT)

Objectives: The aim of this work was to develop expedite procedures to reduce *Staphylococcus epidermidis* adhesion to materials normally used

in indwelling medical devices such as catheters and prosthesis using only a pre-contact of the material surface with two conditioning substances: heparin and gentian violet. Heparin is a proteoglycan with strong anticoagulant activity, normally used to minimise thrombus formation, and gentian violet is a triphenylmethane dye that is normally used as a biological stain and as antiseptic agent.

Methods: Three clinical *S. epidermidis* strains were studied: 9142-M10, 9142 and IE186. Acrylic and silicone were used as substratum. Coupons (2 cm × 2 cm) were immersed in heparin or in 1% gentian violet solution, left to soak for 2 hours and left to dry overnight at 21 ºC. For the adhesion assays, the coupons were placed in 6 well tissue-culture plates with 4 mL of a cell suspension (1×10^9 cells/ml), for 2 hours, at 37ºC and 120 rpm. Each coupon was then stained with 4,6-diamino-2-phenylindole (DAPI) solution and adhered cells were visualised under an epifluorescence microscope and enumerated with appropriated software. The coupons with adhered cells were also observed by scanning electronic microscopy (SEM).

Results: The results of the adhesion assays point to a significant decrease in bacterial adhesion to silicone and acrylic after pre-contact with both conditioning substances. The only exception was observed for strain IE186, which adhered at a similar extent to acrylic pre-contacted with gentian violet and non-pre-contacted acrylic.

Conclusion: The results obtained in this work have a potential clinical significance showing that both heparin and gentian violet are effective in reducing bacterial adhesion. Pre-treatment of biomedical materials with these substances may constitute a successful and expedite procedure to reduce the incidence of nosocomial infections, especially during the insertion of indwelling medical devices.

P1115 Transmission of influenza virus within a French university hospital during three influenza seasons, from October 2004 to April 2007

P. Vanhems, C. Regis, F. Najioullah, B. Barret, C. Gorain, S. Pires-Cronenberger, L. Pollisard, V. Escuret, F. Morfin, B. Comte, D. Floret, B. Lina (Lyon, FR)

Objectives: A prospective study was conducted during 3 influenza seasons at Edouard Herriot Hospital (Lyon, France) from October 2004 to April 2007 to describe nosocomial cases of influenza and to document the role of healthcare workers (HCW) in the transmission of this virus. This hospital counts for 1,000 beds.

Method: In 2004/05 (study #1) 15 wards participated to the study, 36 wards in 2005/06 (study #2) and 39 in 2006/07(study #3). HCW and hospitalised patients with Influenza Like Illness (ILI) syndrome were included. A nasal swab was taken for virological diagnosis. Medical history and vaccination status were collected for each case. Nosocomial cases were defined as occurring after at least 72 hours of hospitalisation for the patients or exposure to an infected colleague or a patient for HCW. Descriptive statistics were used for data reporting.

Results: A total of 872 ILI cases were identified, 71 in 2004/2005, 365 in 2005/2006 and 436 in 2006/2007. Children (Ch) were included only in studies #2 and #3. The sample counted for 168 adult patients (AP), 151 HCW and 553 Ch. There were 39 AP, 27 HCW and 90 Ch with laboratory confirmed influenza; 21 nosocomial influenza cases were observed; 13 for the AP, 5 for the HCW and 3 for the Ch. In study #1, 9 transmissions were observed from patient to patient (n = 3), from patient to HCW (n = 3) and from HCW to HCW (n = 3); in study #2 one transmission was observed from patient to HCW and in study #3, 11 transmissions were observed from patient to patient (n = 3), from patient to HCW (n = 3) and from HCW to HCW (n = 3). 2 patients with severe underlying disease and with confirmed hospital acquired influenza died. Among ILI cases 77/168 AP, 14/553 Ch and 47/151 HCW were vaccinated against influenza. 21 (15%) cases of confirmed influenza occurred in 138 vaccinated individuals (16 patients and 5 HCW). In study #1, circulating influenza A strain differed from the vaccine strain. Communautary influenza epidemic was moderate during study #2 and #3. In study #2 Influenza B was more prevalent and might be more easily transmitted than influenza A.

Conclusion: Nosocomial influenza occurred at each season which highlights the need of using appropriate preventive measures for control. Most transmissions were from non-vaccinated individuals, underlining the importance of vaccinating HCW to limit transmission.

P1116 How does vaccination of healthcare workers affect the number of influenza virus infections in nursing home patients?

C. van den Dool, E. Hak, J.C.M. Heijne, M.J.M. Bonten, J. Wallinga (Utrecht, NL)

Objectives: In epidemiological studies an increase in influenza vaccine uptake by institutional health care workers (HCWs) was associated with decreased influenza illness and mortality rates during the influenza season among nursing home patients. Since these studies were restricted to a small number of nursing homes in few influenza seasons with different vaccine-strain matching and vaccine coverage, the generalizability of these findings remains uncertain. We, therefore, developed a simulation model to determine the effects of increased influenza vaccine uptake by HCWs on influenza attack rates among nursing home patients in different scenario's and for different vaccine coverage levels.

Methods: We use a stochastic individual-based model with discrete time intervals to simulate influenza virus transmission in a 30-bed long-term care department. We track patients and staff and their stage in the influenza virus infection cycle: Susceptible, Exposed (infected but not yet infectious), Infectious and Recovered/immune. An individual's risk of being infected depends on the number of contacts it has, and the likelihood that the contacted persons are infectious.

Individual vaccination is assumed either to induce perfect immunity against infection or to have no impact at all. Most parameters in the model are based on earlier observations (e.g. latent and infectious periods, contact structures). The impact of uncertainty in some parameters (such as vaccine efficacy and transmission probability) was evaluated using a Latin Hypercube Sampling uncertainty analysis.

Results: Increasing vaccination of HCWs decreases the number of influenza virus infections in patients linearly; for every 25% of HCWs vaccinated, the patient attack rate decreases with 4%. No herd immunity is observed. The maximal relative risk reduction for patients (when HCW vaccination rate increases from 0% to 100%) is 67%. Increasing vaccination of HCWs decreases both the number of introductions of influenza virus into the patient population, and the total number of infections following an introduction. Variation in attack rate per department is high.

Conclusion: Increasing vaccination of HCWs can prevent a large fraction of influenza virus infections among nursing home patients and reduce the number of institutional outbreaks. The absolute risk reduction for patients is equal for every 10% increase in vaccine coverage among HCWs, independent of the initial coverage.

P1117 Enterobacteriaceae producing extended-spectrum β-lactamase: duration of carriage and implication for surveillance

C. Bellini, I. Nahimana, L. Senn, A. Wenger, P. Francioli, G. Zanetti (Lausanne, CH)

Background: In 2004–2005, ESBL-producing enterobacteriaceae (ESBL-E) were found in 1.2/1,000 patients in our hospital. ESBL-E were of CTX-M type in 79% of the cases (Lartigue MF et al, AAC 2007), and represented 0.7% of all enterobacteriaceae. In 2006, the rate of colonisation/infection by ESBL-E raised to 2.2/1,000 patients, representing 1.7% of all enterobacteriaceae. No outbreak was detected. This increase prompted more stringent infection control measures in addition to contact precautions, which included routine screening of ESBL-E carriage in all readmitted patients with a history of previous infection/colonisation by ESBL-E.

Objective: To describe the duration of ESBL-E carriage.

Setting: 850-bed general university Hospital.

Method: Duration of carriage was described in patients for whom follow-up screenings were available. These included i) readmitted patients with a history of ESBL-E, who were identified by an automated alert and underwent rectal swab and culture of any previously positive site; and ii) patients who had non-systematic serial screenings because of prolonged hospital stay.
Results: From April 2006 to November 2007, ESBL-E was detected in 91 new patients. Detection occurred <48 h after admission in 46/91 (51%); ESBL-E were *Escherichia coli* in 69 cases (76%) and *Klebsiella pneumoniae* in 15 (16%). 47/91 new patients had 1 to 9 (median 2) follow-up screenings in the context of either a prolonged hospital stay or a new admission. In addition, 9 patients with history of ESBL-E before the study period had 1 to 8 (median 2) follow-up screenings in the context of a new admission. In the total population of 56 patients with follow-up screenings, 38 (68%) had persisting colonisation after a median period of 56 days (range 1 to 608). The other 18 (32%) were eventually negative after a median period of 126 days (range 8 to 358).
Conclusion: prolonged carriage of ESBL-E is frequent, which warrants routine follow-up screening of all patients with a history of infection or colonisation by ESBL-E at the time of new hospital admission.

P1118 Biological monitoring of sterilisation procedures in dental offices in Venezuela

T. Bello, A. Lodato, C. Arango, C. Marrero, J.H. de Waard, L.A. Guevara (Caracas, VE)

Objective: To evaluate the incidence of sterilisation failures in a convenience sample of dental offices in Venezuela.
Methods: 284 strips with spores of *Geobacillus stearothermophilus* and *Bacillus atrophaeus* and an evaluation form were distributed to dentists interested in participating in this study. The dentists mailed the processed strips and the evaluation form to the laboratory for culture.
Results: Tests were submitted from 108 dental offices. The sterilisation methods were convection dry heat (93%) and steam under pressure (7%). A total of 32.4% sterilisation failures were detected. Convection dry heat failed with 32% (32 out 100) and steam sterilisation with 37.5% (3 out of 8)
Conclusion: A high percentage of failures occurred in the sterilisation of instruments reprocessed for the use in patient treatment. Steam under pressure failed more often than convection dry heat sterilisation. These results show the need for official guidelines to be developed by Venezuelan health authorities and to make it compulsory for dentists to biologically verify sterilisation processes. When corrective action is taken, routine use of spore strips for quality control could increases patient safety.

P1119 From "chicken run" to quality care and best practice in management of patients with infections caused by extended-spectrum β-lactamase-associated bacteria

A. Guleri, R. Palmer, B. Lunt, K. Lunt (Blackpool, UK)

Objectives: Recent ITV show and press news successfully drew the attention of public and doctors towards the overlooked rising problem in community with ESBL-producing strain of *E. coli*, associated mortality, association with consumption of foreign poultry and limited national surveillance. This media coverage did miss the complete picture. High quality patient care and best medical practice has been a top priority at Blackpool Victoria Hospital that witnessed rapid rise in ESBL associated infections especially community patients with UTI. This surveillance study over 2 $\frac{1}{2}$ years provides data on rising rate of ESBL infections in hospital and community, associated variations, susceptibility, and guides our strategy of optimal management of community and hospitalised patients.
Methods:

- Laboratory data on ESBL testing (since February 2005);
- Research: Comparing single plate double disk synergy technique with four combination disc technique plates for ESBL testing.
- Direct ESBL screening/confirmatory test on positive blood cultures.
- Standard comments on reports: multidrug resistance mechanism, infection control protocol and discussion with microbiologist in planning management.
- Risk stratification approach for severe sepsis in admission and emergency units.
- Enhanced liaison with GPs for patient specific discussion;
- Raising awareness.

Results: Rising rate of ESBL positive bacteria, especially *E. coli* seen in the last 2 $\frac{1}{2}$ years (refer graph). 619 isolates were confirmed ESBL positive. 34.5% (community specimens). Overall 70.1% (urines) and 10.5% (blood cultures). *E. coli* (62%), followed by *Klebsiella* sp. and *Enterobacter* sp. (approx 20% each). Overall susceptibility of *E. coli*: Ciprofloxacin, Gentamicin and Tazocin (16 – 50%). Urinary *E. coli*: nitrofurantoin (79%), trimethoprim (18%), ciprofloxacin (14%), gentamicin (71%), tazocin (46%). Susceptibility to imipenem 100%.
Conclusions: There has been a rapid emergence of CTX M-*E. coli* in England causing UTIs in community population. Blackpool is witnessing a similar phenomenon. Our comprehensive approach to the problem has included raising awareness in GPs, hospital consultants and junior doctors (especially from admission units), encouraging patient specific management discussion, regular local surveillance and feedback, and risk stratification approach for sepstic patients in admissions. Single daily dosing IV ertapenem is currently offered from assessment units and in near future to be administered at patients home.

P1120 Epidemiological typing of multi-resistant *Klebsiella pneumoniae* strains by FT-IR

R. Guiomar, O. Preisner, Z. Videira, J.A. Lopes, J.C. Menezes, J. Machado (Lisbon, Oporto, PT)

Klebsiella pneumoniae is an important nosocomial pathogen that has the potential to cause severe morbidity and mortality, not only in intensive care units and amongst paediatric patients, but also in medical and surgical wards.
Objectives: Evaluate the usefulness of a novel application of FT-IR spectroscopy in identification of multiresistant *Klebsiella pneumoniae* (MRKP) clones responsible for nosocomial infection outbreak in Portuguese hospital.
Methods: Seventeen multiresistant *Klebsiella pneumoniae* strains isolated from eleven patients from December 2006 to May 2007 during an outbreak in a Portuguese hospital were studied to identify MRKP clones by antibiotic susceptibility test using the disk diffusion method on Muller–Hinton agar (Kirby–Bauer methodology). For the antimicrobial agents tested inhibition zone diameters were measured and used only with the objective to identify and to compare the different clones. Simultaneously to the antibiotic susceptibility testing, strains were evaluated as well by Fourier transformed infrared spectroscopy (FT-IR – Bruker Optik GmbH). Several pre-processing methods have been investigated and the best treatment was selected based on its contribution for the chemometrics model robustness.
Results: As determined by disc-diffusion antibiotic susceptibility testing, MRKP isolates were distributed into to seven different antibiotypes groups. Two major clones responsible for the nosocomial infection were identified. Eight strains belonged to the same resistance pattern, designated by clone A. Another four strains belonged to another group that shows a different resistance pattern, designated by clone C. The other five strains have shown different resistance patterns while compared with each other as well as while compared with the previous clones. The FT-IR analysis of the same strains showed results concordant with the disc-diffusion antibiotic susceptibility testing and identified clone A and C as the predominant clones.
Conclusion: FT-IR is cheaper, easier and faster to perform and allow the access to the overall information of the bacterial cell. Our results demonstrate that application of FT-IR spectroscopy together with chemometrics methods has considerable potential to effectively fulfil the current requirements for rapid and correct differentiation of closely related strains implicated in nosocomial outbreaks.

P1121 Presence of ESBL-producing Enterobacteriaceae in the stools of outpatients with intra-abdominal infections requiring surgery

S. Algarate, C. Seral, M.E. Llaneza, M. Pardos, R. Chacón, J.C. Salinas, F.J. Castillo (Zaragoza, ES)

Objective: Bowel flora may provide a substantial reservoir of resistant microorganisms and precedes intra-abdominal infections. Their susceptibility patterns may provide useful information for empiric treatment. We determinate the flora that colonises the bowel, the incidence of ESBL-producing and/or carbapenem-resistant Enterobacteriaceae (Eb) and the colonisation by non-fermenters Gram-negative bacilli (NF-BGN) in the stools of outpatients with intra-abdominal infections requiring surgery in 71 selected patients from 2005 to 2007.

Methods: Rectal swabs were collected at baseline and inoculated on MacConkey agar plates (MC), MC supplemented with cefotaxime (CTX) 1 mg/L, MC with ceftazidime (CAZ) 1 mg/l and in modified CCDA containing cefoperazone 32 mg/L. Bacterial colonies were identified from each plate using routine laboratory techniques. Eb growing in antibiotic supplemented media were identified and screened for ESBL production by the double-disk synergy test. Confirmation was performed by E-test with CTX/CTX-clavulanic acid (CA), CAZ/CAZ-CA and cefepime (FEP)/FEP-CA.

Results: Rectal swabs were obtained at baseline in 71 selected patients. In 69 of 71 patients (table) growed Eb and abscence of G– faecal flora in two patients. Nine (12.7%) patients harboured an ESBL-producing Eb (4 *E. coli* CTXR-CAZS-FEPS, 2 *E. coli* CTXR-CAZR-FEPS, 2 *E. coli* CTXR-CAZS-FEPR and 1 *C. freundii* CTXR-CAZS-FEPS) and 9 patients were colonised by NF-BGN (12.7%).

Table: Species of Enterobacteriaceae identified and susceptibility to some β-lactams

		Resistance (%)				Ertapenem	
	n/m	AMC	CTX	CAZ	FEP	MIC_{90}	range
E. coli	77/65	11.68%	14.28%	3.89%	3.89%	0.016	<0.002–0.094
K. pneumoniae	5/5	40%	0%	0%	0%	0.016	0.006–0.016
K. oxytoca	5/5	20%	0%	0%	0%	0.012	0.004–0.012
C. freundii	5/5	80%	40%	20%	0%	0.064	0.006–0.064
P. mirabilis	3/3	0%	0%	0%	0%	0.012	0.006–0.012
E. cloacae	5/4	100%	20%	20%	0%	0.19	0.008–0.19
H. alvei	2/2	100%	0%	0%	0%	0.32	0.016–0.32

n: number of isolates; m: number of patients; AMC: amoxicillin/CA.

P1122 Risk factors of hospital-acquired infections in a neurology-neurosurgery intensive care unit, in a tertiary care hospital, in Turkey

C. Bulut, M.A. Yetkin, C. Ataman Hatipoglu, G.R. Yilmaz, F. Erdinc, E. Yildiz, E. Karakoc, A.P. Demiröz (Ankara, TR)

Objectives: Intensive care unit (ICU)-acquired infections are associated with high mortality, excessive length of ICU and hospital stay, and high hospital costs. The risk factors for nosocomial infections may differ according to the type of ICU. The aim of this study was to evaluate the risk factors for ICU-acquired infections in the patients treated in neurology-neurosurgery ICU.

Method: The study was conducted in Ankara Training and Research Hospital, from May 2006 to May 2007. The patients treated for more than 48 hours in 14-bed neurology-neurosurgery ICU were enrolled into the study. The patients were followed until death or three days after discharge by prospective daily surveillance. Nosocomial infections were identified according to CDC criterias. Risk factors for ICU-acquired infections were analysed with a logistic regression model.

Results: Two hundred and fiftyfour ICU-acquired infections occurred in 160 (36.1%) of 443 patients during 5224 patient-days. The overall rate of ICU-acquired infection was 57.3/100 patients and 48.2/1000 patient-days. The most common site-specific infections were urinary tract infections (38.5%), pneumonia (31.7%), and bloodstream infections (22.9%). Urinary catheter-associated urinary tract infection rate was 23.7/1000 urinary catheter-days; central line-associated bloodstream infection rate was 37.9/1000 central line-days and ventilator-associated pneumonia rate was 31.6/1000 ventilator-days. The utilisation ratios of urinary catheter, central line catheter and ventilator were 0.90, 0.39 and 0.34, respectively.

In univariate analysis, age >60 years, being a neurology patient, presence of nasogastric tube, central venous catheter and arterial catheter, mechanical ventilation were determined as significant risk factors for ICU-acquired infections ($p < 0.05$). Multi-variate logistic regression analysis revealed, being a neurology patient ($p < 0.01$), presence of nasogastric tube ($p < 0.01$), presence of central venous catheter ($p < 0.01$), mechanical ventilation ($p < 0.1$) and parenteral nutrition ($p > 0.05$) as independent risk factors.

Conclusion: In this study, ICU-acquired infection rates were found higher when compared with NNIS results. In interpretation of device-associated infection rates, those high rates made us to take immediate precautions both for decreasing device utilisation and emphasising the importance of device application and care practices.

P1123 Screening cultures for multidrug-rresistant acinetobacter and MRSA in hospitalised patients

M. Garcia, A. Nogués, J. Aramburu, P. Gassiot, F. Barcenilla, A. Manonelles, A. Jover (Lleida, ES)

Objectives: The aim of this study was to describe the microbiological performance of screening cultures (SC) for multiresistant *Acinetobacter* spp. (ACI) and meticillin resistant *Staphylococcus aureus* (MRSA) isolated from hospitalised patients.

Methods: Axillary (A), Faringeal (F), Nasal (N), and Rectal (R) swabs for carriers control of ACI and MRSA received from hospitalised adult patiens were studied during a year (October 2006 to September 2007). In the same period, prospective SC were performed in all Intensive Cure Unit (ICU) patients in the first 24 h of their admission.

Samples were processed by conventional methods, and also in an ACI selective medium (Leeds medium, Bio-Médics, Spain) and in MRSA-ID screening medium (bioMérieux). Identification and antibiotic susceptibility was performed by Wider System ® (Soria Melguizo, S.A., Spain).

Results: We processed 2544 samples (704 A, 963 F, 782 N, and 663 R). 480 of this were from ICU patients. These cultures represent the 11% of all bacteriological cultures received from hospitalised patients in the same period in our laboratory.

113 new patients were colonised or infected by ACI, and 65 of them were detected by SC. Rectal swab was the most useful (51% of 65 patients) followed by faringeal swab (38%). 74% of patients with ACI were from ICU and all but 2 were nosocomial.

In the same year we had 85 new pacients with MRSA, 29% of them were detected in SC. Nasal swab detected 60% of all isolates and faringeal swab 34%. We detected 2 patiens with MRSA at the time of their ICU admittance.

Conclusions: We point out the high work load that screening controls cultures represents for the microbiological laboratory.

The best sample for ACI detection was R, and N was for MRSA. In this setting we found Leeds medium very useful in rectal screening of ACI carriers.

SC were useful in detecting patiens colonised by multirresistant microorganisms in ICU patiens at the time of their admittance

P1124 Information overload or under load! How national knowledge weeks can help busy professionals

S. Wiseman, F. Hansraj, P. Kostkova, G. Jawaheer, M. Catchpole, A. Roy, J. Freed (London, UK)

The National electronic Library of Infection (NeLI) www.neli.org.uk is a single-entry portal to evidence based medical knowledge around infection and covers a broad range of infectious diseases.

The National Resource for Infection Control (NRIC) www.nric.org.uk was launched in May 2005 in response to National Audit Office (2000/04) recommendations for a national infection control manual. The project, funded by the Department of Health (UK), is endorsed by NeLI and provides a single access point to the best available evidence and resources on infection prevention and control.
The overall aim of both NeLI and NRIC is to provide relevant evidence based policy, guidance and quality information, published within the last 5 years (where possible) in a timely manner. The key added value of both sites is the quality appraisal of posted documents, which is conducted in collaboration with major professional societies and expert committees in the UK.
Promotion of the websites is ongoing through conference attendance and publications, but it is often obvious when talking to infectious disease and infection prevention specialists that they struggle to keep up-to-date with guidance, research and policy in this important area. Therefore, in January 2006 we started producing a monthly eNewsletter, which is currently subscribed to by more than 1800 professionals, and this provides information on the latest news, upcoming conferences and new resources added to the websites in the last month.
In an effort to help with either information 'overload' (too much information) or 'under load' (not knowing what you need to know) it was agreed that National Knowledge Weeks (NKW's) were the way forward. The aim was to identify the best resources, policy and expert comments regarding the prevention and/or control, treatment and care of specific diseases, infections and infection control practice for healthcare professionals.
This presentation outlines the three specialist areas promoted through the websites in 2007; Tuberculosis, Seasonal Influenza, and Infection Control along with the subsequent analysis of page views received, the popularity of the page, the geographical location of the incoming traffic and the means of accessing the page through use of the web server logs. The discussion will include an evaluation on whether NKW's add value to the sites and achieve their aim and represent the way forward for 2008.

P1125 Implementation of the "Do Bugs Need Drugs?" programme in British Columbia, Canada

E.M. Blondel-Hill, K. Dreher, D. Patrick, M. Carson on behalf of the "Do Bugs Need Drugs?" Working Group

Objective: To implement a province-wide program for wise use of antibiotics in British Columbia (BC), Canada (population 4.3 million).
Methods: Educational resources for healthcare providers, the public and children were adopted directly or adapted from the Do Bugs Need Drugs? (DBND) program, which originated in 1998 in the adjacent province of Alberta. DBND key messages promote: 1) handwashing prevents infections, 2) bacteria and viruses are different, and 3) use antibiotics wisely.
In 2004, based on the success of DBND in Alberta, the British Columbia Ministry of Health provided $1.4 million to implement the program in BC. A program coordinator and assistant were hired. A steering committee with representatives from all health regions was organised as was a DBND working group. An extensive training program was developed with nursing students to teach Grade 2 (7–8 year olds) and daycare children. A 20 page parent guide was distributed to all public health units. A mail out of print materials and an antimicrobial reference guide was distributed to all physicians, dentists and pharmacists in the province. A provincial media campaign included advertisements on television, in movie theatres, parent magazine, and public transportation stations, buses and trains. Collaborations were established to follow prescribing rates and resistance patterns over time. An initiative with a food/pharmacy chain has been established for pharmacy personnel to deliver the program in communities throughout the province.
Results: Since 2004, educational materials have been distributed to 8665 physicians, 1078 trainees, 3795 pharmacists and 2865 dentists. Continuing education sessions have been provided to 863 physicians, 175 pharmacists, 210 infection control practitioners, 400 nurses and 520 nursing students. The Grade 2 program has targeted 12,950 children (>40% of Grade 2 children in Vancouver) and the daycare program has targeted 3384 children, 441 care providers and 39 childhood education students. The televison advertisement has reached 75–85% of the target audience (females aged 25–54) an average of 6–12 times over a 4 week period.
Conclusions: Recognising that health promotion campaigns have a significant delay between education and outcomes (in this case, reduced rates of antibiotic resistance), the BC government has committed an additional $2 million over the next three years.

P1126 Improving outbreak management by understanding barriers faced by professionals in hospitals and public health

A. Timen, M. Hulscher, D. Vos, J. van Steenbergen, R. Grol, J. van der Meer (Bilthoven, Nijmegen, NL)

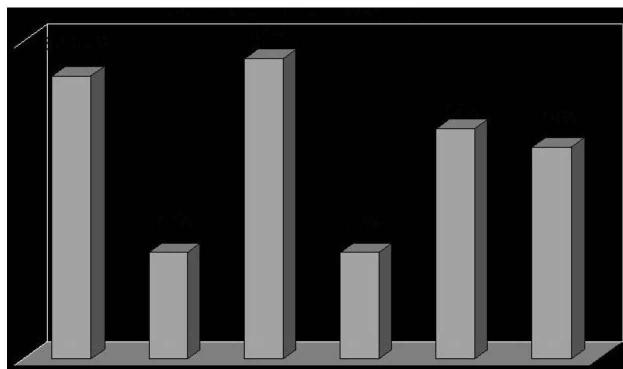
Objectives: The effectiveness of outbreak control depends substantially on the adherence to guidelines. Adherence to guidelines is often not optimal and this has been related, among others, to knowledge, attitudes and behaviour of professionals. Little is known about the factors that influence adherence to authoritative guidance in emergency situations. This study aimed at identifying the most important constraints and facilitators related to professionals in order to improve the quality of outbreak management.
Methods: To qualitatively study and understand barriers to appropriate outbreak control, 26 in-depth interviews with hospital microbiologists and infection control professional and public health physicians and nurseswere carried out in the Netherlands. The conceptual framework of Cabana (JAMA, 1999) was used to discuss recommendations on case finding, infection control, diagnosis, treatment and prophylaxis taking into account recent crisis situations (SARS, outbreaks of *C. difficile* ribotype 027, rubella outbreak). After classifying the barriers, questionnaires were developed for each group of professionals including: 38 items for public health physicians, 40 items for microbiologists, 26 items for infection control professionals and 40 items for public health nurses. The questionnaires were subsequently administered to hygienists in hospitals (N= 95), physicians and nurses in public health services (N=33) and a representative sample of microbiologists (N=30). A five point, asymmetric Likert scale was used to assess appropriateness of each item.
Results: The response amounts 96% for the public health physicians, 84% for the public health nurses, 63% for the hygienists. The study is still ongoing among microbiologists. Preliminary results show that adherence increases when outbreak control measures are evidence based, do not disturb the daily routine in the hospital/department and take into account the safety of the personnel. Effective communication between microbiologists and clinical specialists increases the adherence to infection control measures and therapy recommendations.
Conclusions: The quality (evidence based development, applicability) and timeliness of scientific guidance during emergency situations are among the most important predictors for the reported adherence by professionals. Further qualitative and quantitative analysis of the data will provide a comprehensive basis for tailored interventions to improve adherence.

P1127 Compliance with contact precautions in acute care teaching hospital

M. Alkaabi (Alain, AE)

Introduction: The essential factors for limiting the spread of Meticillin resistant *Staphylococcus aureus* (MRSA) are the surveillance cultures of MRSA infection or colonisation in high risk group of patients admitted to the hospital in addition to the use of contact precautions. On the other hand, poor adherence to contact precautions and poor hand hygiene practices among healthcare workers (HCWs) are among the main reasons for the nosocomial spread of MRSA and failure of the infection control programs.

Methods: Between May 2nd and Jun 5, 2005 we conducted an observational study to monitor the overall compliance with the contact precautions with regard to MRSA among doctors, nurses, medical students and other HCWs during routine adult patient care. These precautions included: hand washing; usage of gloves, gowns and mask, and cleaning equipments after usage. This observational study was conducted in the setting of acute healthcare teaching hospital. The observation was performed in 10 hospital inpatient units which had patients who were colonised or infected with MRSA.
Results: We observed more than 455 opportunity of compliance to the ICPs. 130 opportunities were observed among males and 325 among females. These observations were as follows: among doctors were 94; nurses were 199, among medical students were 50 and among other HCWs were 114 observations. The overall compliance rate of all HCWs to the ICPs was 67%. Compliance observed among males was significantly less than among females, 73% vs 80% (P= 0.05). The overall compliance rate to hand washing was 77% (fig. 1).



There was no significant difference in hand washing compliance rate between doctors and nurses 82% vs 83% respectively (p= 0.9). However, the observed nurses were statistically more compliant to put on gowns (p = 0.02), gloves (p = 0.02) and masks (p = 0.01) than doctors. The rate of cleaning equipments when removed from the patient room by any HCW was only 25%. Eighty five percent of the observed HCWs preferred to use alcohol-based dispensers than the soap and water.
Conclusion: Unlike other investigators, we found that nurses washed their hands not more often than did doctors but both groups washed there hands more often than medical students and other healthcare workers. This is because nurses and doctors had the most opportunities (82% & 83%) to wash their hands.

P1128 Analytical study of infection control measures in Russian ICUs: lessons from real life

R. Kozlov, D. Galkin, A. Fokin, V. Mischenko (Smolensk, RU)

Introduction and Purpose: Epidemiological assumptions show that 2–2.5 millions of patients acquire healthcare associated infections (HAI) in Russia annually. To uncover reasons for the high prevalence we aimed to assess common practices of infection control (IC) in Russian ICUs.
Methods: The study was conducted in 38 multidisciplinary (MD) ICUs from April to August 2007. Project coordinators worked in each of 23 cities and distributed specific questionnaires among ICUs medical doctors. The data were than collected and analysed in reference centre of the institute of Antimicrobial Chemotherapy of Smolensk State medical Academy.
Results: Out of 400 ICU physicians' questionnaires 84.5% were from MD and 15.0% from specialised hospitals (SH). No information was provided in 0.5%. Absence of single patient rooms for isolation was noted in 57.5%; presence of one single room was indicated in 12.8%, 2 – in 20.3%, 3 and over – in 9.1% of respondents' answers. Duration of stay in MD hospitals varied from 1.9 to 18.0, in SH – from 1.9 to 36.0 (average 4.5 days). Availability of liquid soap and/or alcohol hand rub doser in wards was registered in 74.8% of respondents' answers. Use of individual alcohol hand rub solutions after contact with patient reported 62.8% of respondents. Presence of HAI guidelines on antimicrobial chemotherapy was registered by 51.8% respondents only. Compliance with guidelines averaged 82.3%. No guidelines for insertion and catheter care reported 10.8% respondents. Routine MRSA carriage screening on admission to MDH was registered in 17.8% of respondents and in 26.7% for SH; routine use of mupirocin for MRSA decolonisation was registered in 3.6% of respondents in MDH and in SH – in 38.3%.
Discussion: Official statistics indicates prevalence of 30,000 of HAI in Russia annually. This was one of the very first studies to assess real situation with IC that found comparatively low compliance with existing measures in ICUs in combination with virtual absence of quintessential barrier measures, use of alcohol hand rub solutions and adherence to guidelines.

P1129 European survey and consensus on infection control standards and performance indicators

B. Cookson, D. Mackenzie, A. Coutinho, A. Gilsdorf, I. Russell, J. Fabry (London, UK; Copenhagen, DK; Lyon, FR)

Objectives: To assess the situation in European Member States (MS) regarding the progammes, structures and processes in place for HCAI and AMR stewardship and whether there was a consensus amongst infection control professionals and leading healthcare workers for proposed standards and performance indicators (SPIs).
Methods: A questionnaire survey was performed in all MS to explore the current situation. A steering group (Andreas Voss, Peet Tull, and Carl Suetens) helped inform the project group as to the design of national and local SPIs, which were then to be explored in detail, as well as practicality and level of detail. We used the results of several EU consensus meetings and DG SANCO documents on HCAI/AMR that had been explored with MS's departments of health. Data were analysed within Excel(TM) spreadsheets.
Results: 29 (88%) of the 33 MS replied. Analyses showed that 72% had a national HCAI, and 62% an AMR, programme. National laws were in place (55% HCAI/32% AMR). Reductions in HCAI/AMR were targets for approximately two-thirds of programmes, but much variation in responsibilities (9 explored) and topics covered (9 explored) e.g. only 12 MS produced an annual report and 14 covered aspects of occupational health. The same was true for PIs (7 explored), e.g. only 5 considered hand hygiene. Training was considered in only 43% for HCAI and 71% for AMR. HCAI surveillance (78%: 59% compulsory, 41% recommended) and AMR (95%: 55%, 45%). The results clearly indicated a wide variation and the need for a consensus. National and local SPIs were developed: five groups with 51 SPIs. 82% (28/34) MS responded: an average of 83% agreed with these, 12% agreed with alteration, 2% were neutral and 3% disagreed. There were 138 statements of underlying principles relating to these SPIs (82% agreed; 6% with alterations, 5% neutral, 3% disagreed. 89% thought the tools were practical, 57% thought the level of detail was about right but 39% thought it was too much.
Conclusions: We have described a wide variation in SPIs in Europe and proposed SPIs that had a high level of agreement with relevant healthcare workers. Further discussions will need to take place within the project and with MS to explore issues of practicality.

P1130 Optimising the flow of ID-AST information between microbiology laboratory and intensive care unit with the new feature of EpiCenter version 5.5 connected to the BD Phoenix system

E. Ronco, C. Lawrence, P. Louis, C. Boudry, B. Clair, A-L. Roux, M. Rottman, J-L. Gaillard, D. Annane, J-L. Herrmann (Garches, FR)

Objectives: Rapid ID and AST can have a significant impact on the management of infections especially with the spread of multidrug resistant bacteria to the community. Recently released systems that perform automated ID and AST, benefiting from advanced expert systems, can impact the workflow of the microbiology laboratory for a typical hospital. The connection to the hospital information network enhances the transmission of microbiological results from the lab to

the primary care physician, thus potentially affecting the management of the patient. Whether this direct link improves patient's care is still questioned. In this pilot study, we compared the transmission by courier of paper printout results from the laboratory to the ICU to that using the new feature of EpiCenter version 5.5 ID-AST system (BD Diagnostic Systems, USA).
Methods: During a period of 15 days, we measured times to effective transmission, from Gram stain, culture, ID-AST to final validation (internal turn-around time [TAT]), from final validation to ICU, and from ICU to the prescriber (external TAT). EpiCenter version 5.5 connected to the Phoenix ID-AST system was not connected to the laboratory informatic software during this study.
Results: Internal mean and median TAT from preliminary results to validation was 1 h47mn and 30mn respectively [0–19 h15mn] and internal mean and median TAT from ID and AST results to validation was 2 h42mn and 2 h respectively [30mn-6 h30]. Internal TAT by EpiCenter was 0mn, as the system together with the Phoenix ID-AST automate allowed electronic networked transmission after validation.
By courier, median and mean TAT for preliminary results and/or ID-AST results only were 25 h10mn and 55 h55mn respectively. By comparison, median and mean TAT with the use of EpiCenter were 21 h36mn and 25 h11mn respectively.
When considering the time between specimens' arrival in the laboratory and the final results' transmission to the ICU and to the prescriber, external mean and median TAT from validation to ICU by courier was 3days-21 h-31mn and 3days-8 h-47mn respectively. By comparison, median and mean external TAT with the use of EpiCenter were 1day-19 h-55mn and 1day-8 h-18mn; which correspond to a 55% time reduction.
Conclusion: We observed a 55% internal and external mean TAT reduction. This encouraging result will allow us to set up a protocol investigating benefits in clinical outcome provided by real-time ID-AST results transmission.

Infections in the immunocompromised host

P1131 Pneumonia in patients with cancer

C. Gonzalez, T. Johnson, S. Evans, K. Rolston (Houston, US)

Objectives: The epidemiology of infections in cancer patients undergoes periodic changes which impact empiric therapy. Pneumonia is the most common site of infection in such patients. Our primary objective was to describe the current microbiology of pneumonia in cancer patients presenting to our emergency centre (EC).
Methods: Retrospective review of medical records over a 5 month period in 2006.
Results: A total of 7,784 EC visits of which 272 (3.5%) were due to episodes of pneumonia, occurred. Of these, 98 (36%) had positive cultures from respiratory specimens and/or blood. Fifty-seven (58%) had an underlying hematologic malignancy (HM) whereas 41 (42%) had an underlying solid organ cancer (SOC). Respiratory specimen cultures were positive in 65 patients (66%), blood cultures only in 21 patients, and both blood and respiratory cultures in 12 (12%). Sixty-one patients (62%) had monomicrobial infections, whereas 37 had polymicrobial infections. The proportion of polymicrobial infections was higher in patients with SOC (49%) than in patients with HM (30%). The organisms isolated most often from respiratory specimens of patients with SOC were *Pseudomonas* spp., *Stenotrophomonas maltophilia*, various *Streptococcus* spp. and *Staphylococcus aureus*. A similar pattern was seen in patients with HM. Blood culture isolates were often different from respiratory specimen isolates when both sites were culture positive. *Candida* spp. but no moulds were isolated from patients with SOC, whereas moulds (mainly *Aspergillus* spp.) were isolated from patients with HM. Two mycobacterial infections and one case of PCP were also documented.
Summary and Conclusions: Pneumonia accounts for approximately 3.5% of EC visits at our Comprehensive Cancer Center. Thirty-six percent of these episodes are microbiologically documented. Organisms that cause community acquired pneumonia in other patient populations (*Streptococcus pneumoniae*, *Haemophilus influenzae*, *Legionella* spp., *Mycoplasma pneumoniae*) are seldom seen in cancer patients. Consequently, empiric therapy for cancer patients presenting with pneumonia may vary considerably from options mentioned in various guidelines. Ideally, empiric therapy should be based on local microbiologic and susceptibility data.

P1132 Detection of *Helicobacter pylori* DNA in liver tissue samples from patients with hepatocellular carcinoma

N. Rizk, S. Zaki, H. Maghraby, M. Rashed, N. Ragab (Alexandria, EG)

Introduction: *Helicobacter pylori* (*H. pylori*) is one of the most common bacteria worldwide found in more than 50% of human population. The presence of *H. pylori* is the main cause of several gastro-duodenal diseases, including peptic ulcer and gastric cancer. It has been designated as class I carcinogen by the World Health Organisation. Chronic *H. pylori* is related to a variety of extra gastric diseases, including liver diseases.
Objectives: the aim of the present study is to evaluate the presence of *H. pylori* in human hepatocellular carcinoma (HCC) to determine if *H. pylori* may contribute to the development of this disease.
Materials and Methods: Liver specimens from 33 patients with HCC diagnosed by histopathology were studied. Tumour tissue samples were examined by polymerase chain reaction (PCR) for the presence of genomic 16S rRNA of *Helicobacter* genus using specific primers. Besides, other genes (26kDa cell surface protein, cagA, vacA) specific for *H. pylori* were also screened by PCR. The specimens were examined for *H. pylori* by immunohistochemical procedure using anti-*H. pylori* antibody.
Results: Genomic sequence of *H. pylori* was found in 11 of 33 (33.3%) tumour tissues. On the other side, *H. pylori* was proved to be immunohistochemically positive in 7 tumour tissues (21.2%).
Conclusion: The presence of *H. pylori* in HCC tissue by means of molecular methods and immunohistochemistry supports the concept of the close association between *H. pylori* and HCC development. But, their eventual role in hepatocarcinogenesis, although it is plausible, remains to be proven.

P1133 SeptiFast PCR combined with blood cultures for the microbiological documentation of fever in neutropenic cancer patients

K. Jaton-Ogay, F. Lamoth, G. Prodhom, L. Senn, O. Marchetti, T. Calandra, J. Bille (Lausanne, CH)

Background: Blood cultures (BC) identify the aetiology in only 1/3 of febrile neutropenic episodes. New diagnostic tools are thus needed for guiding investigations and antimicrobial therapy. LightCycler SeptiFast (Roche) is a real-time PCR for the detection of bacterial (9 G+ and 10 G– species) and fungal DNA (6 species) in blood.
Objective: To assess the utility of SF combined with BC for the microbiological documentation of fever in neutropenic cancer patients.
Material and Methods: Blood samples for BC (4 aerobic + anaerobic sets, Bactec 9140) and SF (4 EDTA tubes) were drawn simultaneously in adult febrile neutropenic cancer patients undergoing myeloablative chemotherapy for haematological malignancies. Microbiological documentation by SF and BC were analysed.
Results: 186 samplings (SF/BC 1:1) were analysed in 119 febrile episodes. 18/186 (9.6%) SF analyses were invalid (contamination of negative control), 12 (6.4%) were inhibited. 88 pathogens were detected in 59/119 (50%) febrile episodes by BC and/or SF (see table).
Using BC as reference, sensitivity of SF was 50%, specificity 64%, PPV 29%, NPV 81% and efficiency 60%. BC were positive in 20/74 (27%) and SF in 14/74 (19%) samplings drawn in the absence of antibiotic therapy. For samplings drawn during antibacterial therapy, BC were positive in only 12/112 (11%), whereas SF detected pathogens in 38/112 (34%, $p < 0.001$).

Conclusions: Septifast combined with blood cultures is a promising tool for the microbiological documentation in febrile neutropenic cancer patients.

	BC and SF (n = 14)	BC only (n = 25)	SF only (n = 49)

P1134 Quantitative CMV PCR in stem cell transplant patients: DNA manual extraction versus automatic extraction

L. Cardeñoso, J. Navarro, J. Azcona, N. Arenal, E. Lomas, P. Sanchez, R. Camara (Madrid, ES)

Introduction: The success of preemptive treatment of CMV infection in stem cell transplant (SCT) recipients before disease progress depends on efficient early diagnostic tests. The aim of this study was to compare a commercial quantitative CMV-PCR assay with DNA automatic extraction (TNAI-PCR) versus manual extraction (CA-PCR) in the diagnosis of CMV infection in our allogeneic STC recipients, comparing the results obtained by PCR with those obtained by antigenaemia (pp65).
Methods: All patients were prospectively monitored post-SCT with antigenaemia (pp65) CINApool® (Argene) and Cobas Amplicor CMV Monitor Test® (Roche) (DNA manual extraction, CA-PCR). A total of 211 blood samples obtained between January 2005 and May 2006 corresponding to 45 CMV infection episodes from 24 SCT patients, were tested retrospectively using COBAS Ampliprep TNAI kit® (Roche) (DNA automatic extraction system, TNAI-PCR).
An episode is defined since the first positive sample by any method until the first negative sample by both techniques. A positive sample was defined by antigenaemia $\geqslant$2 cel/4$\times$10^5 cel and/or PCR $\geqslant$600 copies/mL. Repeated positive samples were considered the same episode. Independent episodes in one individual were considered if there were at least 15 days of negative serial detections. Samples and episodes were analysed independently. Concordance between methods was determined by Kappa and Spearman coefficients. P-values lower than 0.05 were considered statistically significant.
Results: Good correlation was found between CA-PCR and TNAI-PCR (Spearman coefficient=0.8, $p<0.001$). Assuming qualitative interpretation of PCR, good concordance was also found between CA-PCR and TNAI-PCR (Kappa index=0.6, $p<0.001$).
Episodes analysis: As a whole, TNAI-PCR detected 39 out off 45 episodes (86.7%) and by CA-PCR 32 out off 45 episodes (71.1%) ($p=0.07$).
Twenty out off 45 episodes (44.4%) were detected by both techniques at the same time. Five episodes (11.1%) were detected only by antigenaemia, 8 episodes (17.8%) by TNAI-PCR only and 1 episode (2.2%) by CA-PCR.
In 24.4% episodes, TNAI-PCR was earlier than CA-PCR (median = 34 days). Thus in 42.2% (24.4%+17.8%) episodes TNAI-PCR improved CMV detection versus CA-PCR.
Conclusion: Automatic extraction improves sensibility detecting positive samples and lowers CMV infection diagnosis delay time in SCT patients. But in this moment, pp65 antigen detection cannot be replaced by all biological molecular methods.

P1135 Atypical mycobacterial infection in an allogeneic haematopoietic stem cell transplant patient with bronchiolitis obliterans

Ö. Kumbasar, Ö. Akan, G. Tarhan, S. Uysal, A. Azap, H. Akan (Ankara, TR)

Objectives: A 29 years old female with a previous diagnosis of chronic myelogenous leukaemia who had an allogeneic stem cell transplant (ASCT)in 2004 was admitted to the hospital with dyspnea and increased sputum production. After ASCT she had received cyclosporin A for GVHD and at the 9th month of transplantation had a diagnosis of bronchiolitis obliterans (BO). Steroids were started and continued. The course was complicated with lower respiratory system infections that were succesfully treated. 1.5 year after the diagnosis of BO, she was admitted for cough and progressive dyspnea. Chest X-ray revealed a heterogenous infiltration with a cavity in the left lung. Clinical and radiological findings were compatible with pulmonary tuberculosis (TB). Sputum, brochoalveolar lavage TB cultures with Bactec system and ARB were negative. Anti-TB therapy was initiated. There was no improvement and she returned back to the hospital 5 months later reporting that she did not use the drugs because of nausea and vomiting. There was progression on the pulmonary X-ray. Sputum was positive for ARB. She was transferred to the ICU two weeks later because of severe hypercapnia and respiratory failure. She was intubated and ventilated.
Methods and Results: The growth obtained in Bactec system was identified by PCR-RFLP as *Mycobacterium abscessus*. She received imipenem-cilastatin, amikacin and clarythromycin. In one month she improved clinically and pulmonary X-ray findings resolved. One month later, she was again admitted to the ICU because of hypercapnia and acidosis. She was intubated and mechanically ventilated. She had a diagnosis of ventilator associated pneumonia. She died one month after the second ICU admission. *Mycobacterium abscessus* is a very rare pathogen, a rapid grower, and causes disseminated infections in patients with cystic fibrosis, bronchiectasis, fibrosis due to previous mycobacterial diseases, immunosuppressed subjects and in lung transplant recipients. The agent has a tropism for the respiratory tree, produces tuberculoid granulomas with caseous lesions, and resistant to standard anti-TB drugs and is generally susceptible only to parenteral antibiotics and oral macrolides.
Conclusion: ASCT is a complex immunosuppressive state that may predispose to infections caused by any rare pathogen. We think this is the first case with *M. abscessus* infection after ASCT and the structural lung disease (bronchiolitis obliterans) caused predisposition to this infection.

P1136 Bloodstream infections after solid-organ transplantation

S. Serin Senger, E. Kursun, O. Kurt Azap, F. Timurkaynak, H. Arslan (Ankara, TR)

Objectives: Analyzing the characteristics of bloodstream infections occurring in solid organ transplantation (SOT) recipients.
Methods: All bacteraemia among SOT recipients in our institution during the period from January 2002 to December 2007 were included in the study. We performed a retrospective chart review to determine the patient data such as age, gender, the duration from transplantation to a diagnosis of BSI, whether the BSI was hospital- or community-acquired. The primary BSI was defined as the bacterium isolated from blood culture, which is not related to an infection at another site. Otherwise it was defined as secondary BSI.
Results: A total number of 58 BSI episodes in 42 patients were diagnosed. Of these patients 11 (26.2%) were female. The ages of the patients were in the range 18 to 68 years, with a mean value of 42.1. There were 30 liver, 11 kidney, and one liver-kidney recipients. Of the episodes 17 (in 13 liver and 3 kidney recipients) were diagnosed within the first month after the transplantation, 22 (in 10 liver and 2 kidney

recipients) during the 1–6 months period, and 19 (in 7 liver, 6 kidney, and one liver-kidney recipients) after the sixth month. Of the episodes 10 were primary. The most common focus of BSI was abdominal among liver recipients with 35 (97.2%) episodes, whereas it was urinary among kidney recipients with 6 (54.5%) episodes. *Escherichia coli* was the most frequent agent in both groups of recipients. Two episodes were polybacterial. The list of causative agents was shown in the Table.

Table: Frequencies of causative agents of BSI among SOT recipients

Causative agents	Liver recipients	Renal recipients	Liver & renal recipients
Escherichia coli	21	5	–
Nonfermentative Gram-negative Bacilli	7	2	1
Enterococcus spp.	5	–	–
Staphylococcus aureus	4	–	–
Klebsiella pneumoniae	2	2	–
Streptococcus anginosus	1	–	–
Salmonella group D	–	1	–
Enterobacter spp.	2	2	–
Proteus spp.	1	–	–
Klebsiella pneumoniae & *Enterococcus* spp.	1	–	–
Klebsiella pneumoniae & *Morganella morganii*	1	–	–
Total (n = 58)	**45**	**12**	**1**

Conclusion: The number of BSI episodes was highest in the period of 1 to 6 months after the SOT. Secondary BSIs were considerably more frequent than the primary BSIs. The leading foci of secondary BSIs were consistent with the region of transplantation; that is abdominal for liver, whereas urinary for kidney SOT.

P1137 Infections in patients with myelodysplastic syndromes

D.P. Kofteridis, A. Stavroulaki, A. Valachis, C. Kalpadaki, M. Tzanakakis, H.A. Papadaki, G. Samonis (Heraklion Crete, GR)

Objectives: To describe clinical characteristics and outcome of infections in patients with myelodysplastic syndromes (MDS).
Patients and Methods: Infections occurring in patients with MDS, cared for at the University Hospital of Heraklion, Crete, Greece from 2004 to 2007 were retrospectively reviewed.
Results: Fifty four episodes of infection occurring in 32 patients have been studied. The median age of patients was 77 years (range 66–95); 24 (75%) were males. At the time of infection, 9 patients (28%) had been classified as RAEB-I, 7 (22%) as RA, 7 (22%) as RAEB-II, 4 (12.5%) as RCMD, while 3 (9%) and 2 (6%) as RARS and 5q(−) syndrome, respectively. The median length of hospital stay was 9.6 days (range 2–50), while the median white blood cell count on admission was 1700 cells/μl (range 100–5500/μ). The most common was respiratory tract infection [27 episodes; (50%)], followed by urinary tract infection [7; (13%)]. Nine episodes were complicated by bacteraemia. The responsible microorganisms were identified in 19 (35%) of the episodes. The most frequently identified causative organisms were *Staphylococcus epidermidis*, isolated from 4 specimens (21%), *Enterococcus faecalis* from 4 (21%) and meticillin-resistant *Staphylococcus aureus* from 3 (16%). Regarding outcome, patients were classified into 2 groups: those with curable and those with complicated episodes. An episode was defined as complicated if responsible for the patient's death or prolonged hospitalisation (⩾14 days). There were 25 complicated episodes (46%) including 4 deaths (7%). The rest 29 episodes (54%) were curable. Univariate analysis showed a trend of patients with RAEB-I for complicated course as compared to patients with other MDS subtypes (P = 0.051), while patients with grade IV neutropenia (neutrophils <500/μl) developed infections significantly more frequently (P < 0.05). Multivariate logistic regression analysis revealed that grade IV neutropenia is associated with complicated course (OR: 8.306 95% CI: 1.286–51.235, P = 0.026).
Conclusions: Severe infections represent a serious threat for patients with MDS, especially those with grade IV neutropenia. Neutropenia and probably the MDS subtype may predict the relative risk.

P1138 Current trend in the epidemiology of bloodstream infections in patients with haematological malignancies and solid neoplasms in Iasi, Romania

C. Panzaru, M. Dan, I. Miron (Iasi, RO)

Objectives: to characterise the epidemiological and microbiological spectrum of systemic infections in hematological and oncological patients.
Methods: a prospective study of bloodstream infections was conducted between May 2004-June 2006 in two hospitals from Iasi.
Results: We investigated a total of 92 suspected episodes of systemic infections that occurred among 79 selected patients, involving 40 males and 39 females (mean age = 26 years old). There were 45 (48.91%) febrile episodes with positive blood cultures and 47 (51.09%) with negative blood culture. The most common microorganisms were Gram-positive cocci 15 (33.33%), followed by stable cell-wall deficient forms 9 (20.00%), Gram-negative bacili 9 (20.00%), Gram-positive bacili 5 (11.11%), fungi 5 (11.11%), and anaerobes 2 (4.44%). From the total 23 strains of cell-wall deficient forms (51.11%), 14 returned to their typical morphology (6 Gram-positive cocci, 5 Gram-positive bacilli, 3 Gram-negative bacilli) and 9 were L-stable.
Conclusions: (1) The isolation rate, 48.91%, was in accordance with literature reports; similar percentages of Gram-positive and Gram-negative isolates were found (the shift from predominating Gram-negative to a Gram-positive aetiology was noted). (2) We found a high proportion of cell wall deficient forms, rarely reported before. (3) Studies reporting local microbiological findings are necessary because they support an initial empiric antibiotic regimens for prophylaxies or therapy more accurately than from other areas. The right treatment protocols remain to be established.

P1139 *Strongyloides stercoralis* hyperinfection in an immunosuppressed patient with a nephrotic syndrome

T. Baptista-Fernandes, D. Alfaiate, P. Branco, L. Relvas, A. Dias, T. Marques (Carnaxide, PT)

Objectives: Strongyloidiasis is highly prevalent in tropical and subtropical regions, with endemic foci in some temperate areas. Its real prevalence is probably underestimated.
We intend to alert to nephrotic syndrome as an unusual presentation of chronic infection, to the risk of potentially fatal hyperinfection syndrome in the immunocompromised population and, therefore, the need for a high suspicion and accurate laboratory diagnosis.
Methods: We report the case of a 31-year old Cape Verdean woman living in Portugal, admitted with profuse diarrhoea, abdominal pain and dehydration. She had been diagnosed with nephrotic syndrome (minimal change disease) of unknown aetiology four months before and was receiving prednisone and mycophenolate mofetil.
Bacteriological and parasitological investigation included examination of faeces, sputum, urine, blood and cerebrospinal fluid.
Results: A diagnosis of *Klebsiella pneumoniae* sepsis was made and *Strongyloides stercoralis* larvae were found in faeces and sputum. Hyperinfection was considered and mycophenolate mofetil was suspended, steroids tapered and albendazole was started. Eosinophilia on peripheral blood only became evident after suspension of the immunosuppressors (reaching 5.0×10^9/L). Human Immunodeficiency Virus and Human T-limphotropic Virus serologies were negative.
She was treated for a month, with dramatic clinical improvement, regression of the eosinophilia, absence of larvae on stool or sputum and resolution of the nephrotic syndrome (proteinuria was 13 g/day prior to therapy to 1.3 g/day on discharge).
Conclusions: Chronic strongyloidiasis is a rare and reversible cause of nephrotic syndrome.

Immunosuppressive therapy has a high risk of causing fatal hyperinfection or dissemination of *S. stercoralis* and, therefore, screening is advised, in patients with a sugestive epidemiological history, prior to its initiation. Combination of parasitological examination (including faecal concentration and culture) with serology is probably the best approach. The diagnosis of *S. stercoralis* hyperinfection should be considered in immunosuppressed patients from endemic areas presenting with acute respiratory or gastrointestinal symptoms and Gram-negative sepsis, even in the absence of eosinophilia. In these cases other body fluids should also be examined and attention should be payed, on routine examination, to the incidental finding of larvae.

P1140 Molecular evidence of a nosocomial *Pneumocystis jirovecii* transmission among 16 patients after kidney transplantation

S. Schmoldt, R. Schuhegger, I. Huber, H. Söllner, M. Lindermayer, J. Heesemann, L. Bader, A. Sing (Munich, Oberschleißheim, DE)

Objectives: In recent years, nosocomial clusters of *Pneumocystis jirovecii* (formerly P. carinii) pneumonia (PCP) among immunocompromised individuals were reported. Mostly, the source of infections was suspected within the clinical settings when transplant recipients and PCP patients shared hospital facilities.

Methods: We report a cluster of 16 renal transplant recipients positive for *P. jirovecii*. None of them received anti-*Pneumocystis* prophylaxis prior to *P. jirovecii* detection. Epidemiological studies revealed that 15 of them were kidney transplanted at a German university hospital and attended the same inpatient and outpatient clinic from January through September, 2006. Multilocus sequence typing (MLST) was performed on the following genes: ITS1, beta-tub, 26S and mt26S.

Results: *P. jirovecii* DNA was available from 14 patients and showed identical MLST types among these renal transplant recipients. Surprisingly, one patient who was treated at a different nephrological centre and negated personal contacts to patients from the renal transplantation cluster harboured the same *P. jirovecii* MLST type. Three HIV patients and one bone-marrow transplanted hematologic malignancy patient – treated at two different medical centres – were used as controls and revealed different MLST types. Interestingly, in three of the four previously described regions new alleles were detected and one new polymorphism was observed in the mt26S region.

Conclusion: The epidemiological data and the genotyping results strongly suggest a nosocomial patient-to-patient transmission of *P. jirovecii* as the predominant transmission route.

P1141 Critical care-related infections in heart transplant recipients

P. Muñoz, A. Fernández-Cruz, J. Palomo, J. Yáñez, J. Guinea, M. Valerio, J. Hortal, E. Bouza (Madrid, ES)

Objective: Reports on infections of heart transplant (HT) recipients during early postoperative ICU stay (ICU-E) or requiring later ICU readmission (ICU-L) are very scarce. Our aim is to describe these infections in HT before and after use of daclizumab.

Methods: We reviewed ICU infections in our HT cohort (1989 to 2007) and compared ICU-E and ICU-L infections before and after daclizumab (1989–2002 vs 2003–2007).

Results: There were 48 ICU infections in 36/387 patients (9.3%): 25 (52%) ICU-E and 23 (48%) ICU-L.

ICU-E infections: Low respiratory tract infections (11; 44%), catheter-related bloodstream infections (BSI) (6; 24%), primary bacteraemia (2; 8%), mediastinitis (4;16%), gastrointestinal (GI) infections (1; 4%) and other (1;4%). Microorganisms were Gram(–) (12/48%), Gram(+) (9/36%), *Aspergillus* (2/8%), *Candida*, and *C. difficile* (1;4% each). All mediastinitis, 53.8% of the BSI, 45.8% of the pneumonias, and only 17% of the septic shocks occurred in the ICU-E stay. Mortality was 35% (7/25).

Median time to ICU readmission was 87 days (IQR:51–1037) and 52% of the infections were nosocomial. ICU-L infections were pneumonia (13/23; 56.5%; only 2 ventilator-associated pneumonia), disseminated infections (4; 17%), GI CMV infections (2; 8.6%), and others (4; 17%). All CMV infections (5/22%) and 4/6 aspergillosis occurred as ICU-L readmissions. Gram(–) (9; 39%) and Gram(+) bacteria (3; 13%) were also detected. Attributable mortality was much higher (13; 56%).

When pre- and post-daclizumab periods were compared, we detected a disappearance of all opportunistic infections (CMV, *Aspergillus*, *Pneumocystis*) requiring ICU admission in the post daclizumab period. From 2002, mortality per episode decreased (19/35 vs 1/13), as did the need for ICU readmission due to infection (1.6 vs 0.4 episodes/year).

Conclusion: 9% of HT recipients will have an infection during their ICU stay (52% in the first post-HT ICU admission). Opportunistic infections, septic shock, and BSI are extremely rare today, thus reducing the need for ICU readmission. Mortality of HT patients who are readmitted because of infection is high (56%).

P1142 Isolation of Asaia sp. in two bacteraemia cases in patients with idiopathic dilated cardiomyopathy awaiting heart transplants

S. Juretschko, T. Beavers-May, L. Helsel, A. Steigerwalt, S. Stovall (Little Rock, Atlanta, US)

Objectives: The genus Asaia consists of 3 species, A. bogorensis, A. krungthepensis, and A. siamensis, all described as acetic acid bacteria and originally isolated from tropical flowers in SE Asia. A. bogorensis is the only species that has been associated with human disease, in a case of bacteraemia and another of peritonitis. A fourth species designation, "A. lannaensis", is unpublished; however, a corresponding sequence has been deposited in GenBank. Here we describe the first two cases of nosocomial infections with Asaia sp., closely affiliated to "A. lannaensis".

Case study: Two patients, 15 months and 5 years old, with idiopathic dilated cardiomyopothy awaiting cardiac transplantations in one unit at Arkansas Children's Hospital developed bacteraemia. Both patients within one week developed similar symptoms, such as high grade fever, hypotension, leukopenia, and thrombocytopenia. Multiple blood cultures drawn from PICC lines, central venous lines and a peripheral culture (from one patient) were positive for Gram-negative rods. Isolates from both patients were non-motile, non-hemolytic, strictly aerobic, catalase positive and showed negative reactions for oxidase, indole, urea and esculin hydrolysis. The pink pigmented colonies grew on blood and chocolate agar, but not on MacConkey and Mueller-Hinton. Growth was seen at 25 and 35ºC, but not at 42ºC. The BD Phoenix identified the organisms as *Pseudomonas luteola* and *Acinetobacter baumannii* with confidence values of 99 and 90%, respectively. The Remel rapID NH kit resulted the pathogen as *Gardnerella vaginalis* with a probability of >99.9% in each case. Non-matching biochemical results excluded these organisms for true identification. The organisms were submitted to the CDC for 16S rDNA sequence analysis and extensive biochemical tests revealing that both strains are 100% identical to each other. Further phylogenetic analyses showed the two unknown organisms to be 100% identical with A. lannaensis and a 99.6% similarity with A. bogorensis. Both patients received 14 days of meropenem and had their lines removed. Subsequent both patients recovered and received heart transplants.

Conclusion: This is the first report of human infection with the bacterium "A. lannaensis". The physical location of both patients, the temporal association of infections as well as the isolation of two identical pathogens suggests a nosocomial infection. An epidemiological investigation did not identify a source of this organism.

P1143 *Aspergillus* galactomannan antigen in liver transplant recipients: a high false-positive rate in serum samples obtained during the first week post-transplantation

J. Fortun, P. Martin-Davila, M. Alvarez, A. Sanchez-Sousa, L. Gajate, R. Barcena, J. Nuño, S. Moreno (Madrid, ES)

Background: *Aspergillus* galactomannan antigen (GM) is a useful tool as early marker of patients at risk to develop invasive aspergillosis (IA),

but it could have false-positive (FP) results. The causes of FP reported are varied like some foods, altered intestinal barrier, other types of fungi and semi-synthetic β-lactam treatments, especially piperacillin-tazobactam.

Methods: From jul-03 to Apr-07, a prospective study, testing periodically GM in serum samples of liver transplant recipients (LTR), was performed in our Institution. Platelia *Aspergillus* EIA-sandwich microplate assay was used following the manufacturer recommendations. Samples with an index >0.5 were considered positive. GM test was performed weekly during the 1st month after transplantation. Uni- and multivariate analysis were performed to evaluate the relation of false positive GM with clinical circumstances or therapeutic procedures after transplantation. In vitro studies including diferent β-lactams were tested for the presence of Asp-GM by use of Platelia *Aspergillus* test.

Results: During this period, 3 pts (3.4%) had a diagnosis of IA and GM were positive in 2 of them. After excluding patients with IA, a total of 414 serum samples from 85 LTR were analysed. Mean number of samples per pt was 4.8 (median:4.0). The number of FP of GM was 40 (9.6%), corresponding to 28 pts. FP GM in samples obtained during the 1st week post-transplantation was 36% (27 of 75), in comparison to 3.8% (13 of 339) in samples obtained after the 1st week ($p < 0.001$). Multivariate analysis showed that prophylaxis with ampicillin was the only independent factor related with a FP GM. In vitro studies showed a positive GM results (>0.5) in 4/6 ampicillin vials, in 3/6 piperacillin-tazobactam vials, in 0/6 cefotaxime vials and in 0/6 controls.

Conclusions: The frequency of FP GM in LTR in our centre was significantly high during the 1st week post-transplant. The present study suggests that ampicillin administered as prophylaxis to our patients during the first 2 days could be the cause of FP GM. Due to the timing of IA in these patients, it seems advisable and safety to delay GM monitorisation in these patients

P1144 Prospective study of infectious complications in a cohort of 54 consecutive allogeneic haematopoietic stem cell transplant recipients

A. Martín-Peña, M. Aguilar-Guisado, I. Espigado, R. Parody, J.M. Cisneros (Seville, ES)

Objectives: To determine the incidence, aetiology and mortality during the first 2 years after transplantation in allogeneic stem cell transplant recipients (allo-HSCT).

Methods: Prospective, observational study of a consecutive allo-HSCT adult recipients cohort, between July-03 and May-06. Descriptive analyses of infection and mortality.

Results: 54 consecutive allo-HSCT recipients were included, median age 40.5 years (16–58), 52% males. Median follow-up was 180 days (9–720). Eighty-two infections occurred in 41 patients. Incidence of infection was 1.4 episodes/patient during the first year and 2 episodes/patient during the first 2 years after transplantation. In the pre-engraftment period (PEP) the incidence of infection was 0.5 episodes/patient, in the mid recovery period (MRP) was 0.6 and in the late recovery period (LRP) 0.8. In the PEP there were 29 infections (35.4%), and the most frequent were catheter-related (34.5%), pneumonia (17.2%) and bacteraemia (17.2%). In the MRP there were 27 episodes (32.9%), the most frequent were CMV infection (42.3%), and primary bacteraemia (22.2%). In the LRP there were 26 episodes (31.7%), being the most frequent CMV infection (23.1%) and mucocutaneous infection (23.1%). Etiological diagnosis was established in 65/82 episodes (79.3%). Bacterial aetiology predominated (55.4%), followed by viral (40%) and fungal (4.6%). In the PEP Gram-positive bacteria were the most frequent aetiology (42.8%), followed by Gram-negative (33.3%). There were 2 invasive aspergillosis (9.5%). In the MRP Gram-negative bacteria predominated, together with viruses, all of them CMV (42.3%). In the LRP the most frequent aetiology were viruses (66.6%) mainly CMV (33.3%) followed by VHS (22.2.%). Thirteen patients died during the follow-up (24%) The mortality rate by periods was: 5.5% (PEP), 11.8% (MRP) and 8.9% (LRP). Death was infection-related in six cases (46%).

Conclusions: The incidence of infection after allo-HSCT is high and reaches 2 episodes per patient up to 2 years after transplantation. The most frequent infections in the pre-engraftment period are catheter-related and pneumonia, whereas in mid and late recovery periods is CMV infection. The most frequent aetiology are bacteria, but viruses increase in frequency along the recovery periods and are the most frequent in the late recovery period. Mortality is high, and predominantly related to infection.

P1145 Comparison of quantitative PCR after automatic DNA extraction and pp65 antigen detection for diagnosis of CMV infection in stem cell transplant recipients

J. Navarro, L. Cardeñoso, J. Azcona, N. Arenal, E. Lomas, P. Sanchez, R. Camara (Madrid, ES)

Objectives: Cytomegalovirus (CMV) infection has been recognised as one of the major causes of morbidity in stem cell and solid organ transplant recipients. Efficacy of treatment is closely related to accurate early diagnostic laboratory tests. Quantitation of CMV DNA by conventional polymerase chain reaction (PCR) and pp65 antigen detection in peripheral blood specimens are performed in our department. The aim of this study is the comparison and correlation between the two methods in the diagnosis of CMV infection in our stem cell transplant recipients.

Methods: We retrospectively reviewed peripheral blood samples from stem cell transplant recipients obtained between January 1st 2005 and September 10th 2007. Quantitative PCR was performed using COBAS Ampliprep TNAI kit® (Roche) after DNA automatic extraction, and pp65 antigen was detected by CINApool Anti HCMH ppUL83® (Argene) kit. A positive sample was defined by a pp65 antigenaemia $\geqslant 2$ cel/4×10^5 cel and/or PCR $\geqslant 600$ copies/mL. Episodes were defined as serial positive samples until continued negativity for at least 15 days. Samples analysis and episodes analysis were performed independently. Qualitative variables are expressed as proportions. Concordance between both methods was determined by testing Kappa index and Spearman coefficient. P-values lower than 0.05 were considered statistically significant.

Results: We studied 439 samples, identifying 84 episodes from 53 different patients. Samples analysis: 10.3% of pp65 determinations were non-evaluable and 1.1% of PCR were invalidated. 212 (48.3%) positive samples were detected (18.4% were detected only by pp65, 33.5% only by PCR and 48.1% by both methods). Correlation between pp65 and PCR was medium (Spearman coefficient=0.37, $p < 0.001$). Assuming qualitative interpretation of pp65 and PCR, medium concordance was also found (Kappa index=0.42, $p < 0.001$). Episodes analysis: 19.0% were detected only by pp65, 16.7% only by PCR and 64.3% by both methods. 36.9% episodes were detected at the same time by PCR and pp65. 8.3% were early detected by pp65 and 19.0% by PCR, and in both cases with a median of 7 days.

Conclusions: Medium correlation has been found between pp65 antigen detection and conventional PCR. An important proportion of samples and episodes have been detected only by one test, so both methods are complementary, and PCR cannot replace antigenaemia.

P1146 Evaluation of the cytomegalovirus reactivation after solid organ transplant

P. Perez-Romero, F. Flor-Parra, J. Mier-Mota, A. Martin-Peña, E. Garcia-Prado, M.C. Roque-Cuellar, M. Sanchez, M.A. Gomez-Bravo, E. Cordero, J. Cisneros (Seville, ES)

Objectives: The goal of this work was to determine in solid transplant recipient patients whether or not the valganciclovir preemptive therapy can protect from CMV late disease allowing the early activation of the specific immune response against CMV in T cells.

Methods: We studied solid transplant recipients with high risk for CMV infection. Patients with negative serotype for CMV receiving a CMV-positive transplant were followed. From week two post-transplant, CMV viral load (VL) was determined periodically in blood, using real time PCR with CMV especific fluorescent-primers compared to known

standards. The results of the PCR were used to guide the administration of preemptive treatment with valganciclovir. The same samples were used to quantify CMV VL by the antigenaemia test. We also measured the T cells especific immune response against CMV by flow citometry, detecting especific cell surface markers (CD69 and CD3) and citokines production (IL-4 and IFN-gamma).
Results: We followed a total of 113 transplants (kidney: 55, liver:43 and heart:15). Two of the liver transplant patients had the features for the study. In the first patient, VL was detected by real time PCR 20 out of the 22 weeks (non-consecutives) analysed (VL from 3 to 97975 copies/ml), begining two weeks after the transplant. However, the antigenaemia test was positive on week 5 post-transplant and only two more consecutive weeks. Guided by the real time PCR results valganciclovir preemptive therapy was administered in two cycles from week 3 to 9 and from week 11 to 15 respectively. The CMV especific immune response was positive at week 22 after the transplant, which could contribute to the cleareance of a CMV rebound between weeks 22 and 25 without the administration of valganciclovir.
In the second patient, the PCR was positive 10 out of the 13 (non-consecutives) weeks analysed (VL from 4 to 28907 copies/ml) begining four weeks after the transplant. Again, the antigenaemia test was positive only on week 5 post-transplant. Valganciclovir preemptive therapy was administered from week 4 to 11 and no especific immune response has been detected yet.
Conclusion: Real time PCR provides a rapid, accurate and more sensitive method for early detection of CMV VL, allowing better monitoring of solid transplant recipient patients and early administration of valganciclovir preemptive therapy. Furthermore, in one of the patients the we detected early activation of the especific immune response against CMV.

P1147 Phenotypic and genotypic characterisation of *Neisseria gonorrhoeae* isolated from HIV positive and negative patients in Italy: emergence of ST 661 clone

S. Starnino, N. Bilek, P. Stefanelli on behalf of Neisseria gonorrhoeae Italian Study Group

Objectives: Reliable data concerning the incidence of *Neisseria gonorrhoeae* infections in Italy is lacking, as is information about the phenotypic and genotypic characteristics of circulating strains. Gonococcal isolates (n= 401) collected from patients with or without concurrent HIV infection, were characterised by serovar determination and antimicrobial susceptibility testing. Selected isolates were studied by opa typing, porB sequence analysis and *Neisseria gonorrhoeae* Multi Antigen Sequence Typing (NG-MAST).
Methods: The methods used for phenotypic and genotypic characterisation of the strains were already described in the literature.
Results: The isolates were assigned to three different serovars (IA, IB, IA/IB), with IB the most frequently encountered. Ciprofloxacin, penicillin and tetracycline resistance phenotypes were detected as well as resistance to two or more drugs. Two main opa types were identified accounting for 79.7% among the analysed strains.
Despite the presence of different STs (as identified by NG-MAST), some never detected in other countries, genetic characterisation of the circulating strains showed the persistence of ST661 in a specific geographic area. This large cluster might indicate that re-assortment and DNA recombination are not extremely frequent among strains circulating in that geographical area or alternatively, isolates of this genotype have a fitness advantage over other strains circulating enabling it to persist in the population. The association of this cluster to a drug resistant phenotype could have negatively influenced the infection of individuals, a particular concern in the case of HIV positive patients. The chain of transmission was well established for isolates identified as ST661, as evidence of the power of NG-MAST in the genetic study of gonococci. These results support previous reports on the rates of individuals co-infected with HIV and the circulation of resistant gonococci.
Conclusion: In conclusion, no correlation was found between specific gonococcal phenotypic or genotypic traits with co-infection with HIV-1. Moreover, a large cluster of resistant isolates was detected in Italy despite a low incidence of gonorrhoea. The combination of microbiological and epidemiological data enables the identification of clinically significant strains circulating that would otherwise not be disclosed, such as the ST661 cluster.

P1148 Predictive factors for typhlitis in paediatric oncology patients with neutropenia and abdominal focus

N.R. Rivas, A. Viña, G. Yerino, S. Ceccoli, L. Praino, E.L. López (Buenos Aires, AR)

Several risk factors related to typhlitis in neutropenic patients have been reported. However, few data are available in Latinamerican children. To identify independent risk factors for typhlitis we performed a retrospective cohort study in a Tertiary Care Center between 01/2003–11/2007.
Methods: Inclusion criteria: POP with neutropenia and abdominal focus (AF). Case definition: Typhlitis: AF and bowel wall thinckess ±4 mm by CT scan and/or ultrasonography. Control group: Patients that didn't fullfilled case definition. We excluded patients without AF.
Outcome: Typhlitis. Predictive factors: age, underlying disease, Cytosine arabinoside (ARA C) therapy, fever, diarrhoea, vomiting, abdominal pain and tenderness, sepsis and platelets. Hospitalisation days, microbiologic data and parenteral nutrition were also analysed. Statistical analysis: To compare categorical and continuous data between groups we used Chi-square and Mann-Whithney tests, respectively (error 0.05). The multiple regression analysis included all factors with $p < 0.05$ in the univariate model.
Results: From 82 AF episodes in 63 patients; 24 (29%) were typhlitis. Age: 126 mo (median) r5–211, male 41/82 (50%). Acute Myeloid Leukaemia (AML) typhlitis 10/24 (42%) controls: 9/58 (15.5%) p 0.01 OR 3.8 (CI95% 1.1–13). Cases differed from controls in the presence of fever 24/24 (100%) vs 49/58 (84%) p 0.04; diarrhoea 24/24 (100%) vs 44/58 (75.8%) p 0.008; abdominal pain 22/24 (91.7%) vs 38/58 (65.5%) p 0.01; abdominal tenderness 17/24 (70.8%) vs 10/58 (17.2%) p 0.001; sepsis 14/24 (58.3%) vs 18/58 (31%) p 0.02; platelets 18,000/ul (median) r3,000–370,000/ul vs 48,000/ul r6,000–244,000/ul $p < 0.01$ and ARA C 17/24 (70.8%) vs 24/54 (44.4%). No statistical difference in vomiting and epigastric pain. In the multivariate analysis, factors that remained significantly associated with typhlitis were abdominal tenderness p 0.02 OR 3.1 (CI95% 1.1–8.6) and abdominal pain p 0.02 OR 12.8 (CI95% 1.5–109). Microbiologic agents in typhlitis 9/24 (37.5%) vs 9/58 (15.5%) p 0.03. *Klebsiella* sp. and *E. coli* were most prevalent. Duration of hospitalisation in typhlitis:16.3 d (median) r2–60 vs 10 (3–60) p 0.001. Parental Nutrition in typhlitis 17/24 (70.8%) vs control 3/58 (5.1%) $p < 0.001$. Mortality: 3/82 (3.6%), tiphlitis 2/82.
Conclusions: In POP with neutropenia, images to confirm typhlitis should be done when abdominal pain and tenderness are present. Typhlitis was more frequent in patients with AML, ARA C and severe trombopenia.

P1149 Incidence and risk factors of infection in a single cohort of 110 adults with systemic lupus erythematosus

S.J. Jeong, H.K. Choi, H.S. Lee, B.S. Chin, S.H. Choi, S.H. Han, M.S. Kim, C.O. Kim, J.Y. Choi, Y.G. Song, K.W. Choe, M.W. Kang, J.M. Kim (Seoul, KR)

Objectives: Systemic lupus erythematosus (SLE) is a chronic, usually life-long, potentially fatal autoimmune disease characterised by unpredictable exacerbations and remissions with variable clinical manifestations. Although there is a high probability for clinical involvement of other various organs in patients with SLE, infectious diseases have emerged as one of the leading causes of morbidity and mortality, accounting for 14–45% for SLE-related deaths.
A number of factors have been reported to increase risk of infection in SLE patients. While previously studies have focused on describing risk factors, data regarding predictors of infection at the time of SLE

diagnosis or immediately before the infectious event is deficient. The aims of this study are to describe infectious complications and analyse their risk factors at the time of SLE diagnosis using a single cohort of 110 adults with SLE.

Methods: A retrospective review of 110 patients who met the American Rheumatism Association criteria for SLE from June 1991 to January 2000 was performed. The records were analysed to determine the risk factors for infection by comparing patients who had suffered at least one infectious episode (n = 32; 38%) with patients that had none(n = 38; 60%).

Results: The incidence of infection in 110 patients with SLE was 4.4/100 patient-year. Pneumonia constituted 33 percent (14 cases) of all infectious complications and the most frequently yielded pathogen was *Streptococcus pneumoniae*(20%, n = 3). According to univariate analysis, significant risk factors for infection were: high SLEDAI score, total accumulated dose of corticosteroids, follow-up duration, initial C3/C4/anti-dsDNA antibody/WBC count, frequent flares. Multivariate analyses retained SLEDAI score (⩾13, p = 0.01), C3 (<90 mg/dl, p = 0.01), positive anti-dsDNA antibodies(p < 0.01) at the time of SLE diagnosis as independent predictors for infection and frequent flares(p = 0.04), follow-up duration (⩾8 years, p = 0.023) as independent risk factors for infection.

Conclusion: In lupus patients, infections are most often caused by community acquired bacteria. SLEDAI score, C3 level, anti-dsDNA antibodies are independent predictive factors and disease flare rate, follow-up duration are independent risk factors of infection. On the basis of our findings, it seems mandatory to closely observe SLE patients with factors mentioned above.

P1150 Trends in bacterial isolates from blood cultures and their resistance in relation to the antibiotic consumption at the haemato-oncological department in the period 2000–2006

B. Weinbergerova, Z. Racil, I. Kocmanova, M. Lengerova, J. Lochmanova, P. Volfova, K. Hrncirova, J. Mayer (Brno, CZ)

Objectives: The indiscriminate use of antibiotic (ATB) has contributed to increase the antimicrobial resistance, which has significant influence on mortality rate in immunocompromised pts. Continuous monitoring of pathogens, resistance and consumption of ATB is of cardinal importance for empirical ATB use in hematooncological pts.

Methods: The aim of the study was the retrospective analysis of trends in bacterial strains and their resistance isolated from blood cultures (BC) in large hematooncological dpt. in Czech Republic in relation to the ATB consumption in 2000–2006.

Results: During the entire period the average total No. of BC per year obtained at our dpt. was 4170. The percentage ratio of positive BC from total No. of obtained BC remained around 15% all the time. Gram-positive (G+) strains predominate (70%), but 67% of them were caused by coagulase-negative staphylococci, that are in majority of samples assigned as contaminant. The Gram-negative (G–) strains caused in average 30% of bacteraemias per year during the whole period. 70–80% of all G– isolates consisted of the following strains: *Pseudomonas* sp., *Klebsiella* sp., *Escherichia* sp. and strains of G– non-fermentative bacteria. The development of ATB resistance among isolates of G– strains was following: the resistance of *Pseudomonas* sp. to carbapenems was the biggest issue in 2001 (53%), it resulted in marked decrease of their usage and enhanced usage of the third generation (III. g.) cephalosporins. This led to lower incidence of *Pseudomonas* sp. isolates from BC (2001 – 20% vs. 2003 – 13%) and to its greater sensitivity to carbapenems (2001 – 47% vs. 2003 – 73%). On the other hand No. of ESBL *Klebsiella* sp. isolates rose in 2004. Since 2000 the consumption of amikacin has been significantly increasing which resulted in much higher resistance of *Klebsiella* sp. to aminoglycosides (2000 – 16% vs. 2005 – 51%). More frequent usage of vancomycin and III. g. cephalosporins between 2000 and 2004 was in 2004 reflected in an extreme increase of vancomycin-resistant enterococci (VRE) isolated from BC (40%). An appropriate regimen and marked decrease in usage of the above mentioned group of ATB led to the elimination of VRE in the following years.

Conclusion: Continuous monitoring of isolates from BC and their resistance in relation to the usage of ATB facilitates the choice of appropriate drug for the empirical treatment of febrile neutropenia and thus results in lower morbidity/mortality of pts. and costs of ATB therapy.

P1151 The values of leukocyte count, C-reactive protein, and erythrocyte sedimentation rate for diagnosis of osteomyelitis in patients with diabetic foot ulcers

N. Yapar, B. Akinci, B. Ay, S. Yener, S. Yesil (Izmir, TR)

Objectives: Diabetic foot infections are serious problems in diabetic patients and osteomyelitis is not a rare complication of these infections. In this study, we aimed to investigate the diagnostic values of WBC count, C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) for diagnosis of osteomyelitis.

Methods: Patients admitted to our hospital with diabetic foot ulcers in three years period, from January 2004 to December 2006, were included in the study. Demographical data, duration and classification of foot ulcer, WBC counts, ESRs, and CRP levels were recorded. Reference values of tests were 0–5 mg/dL for CRP and 0–20 mm/h for ESR. Osteomyelitis was diagnosed according to the radiological findings (X-ray and MRI). Sensitivities, specificities, positive and negative predictive values (PPV and NPV) of laboratory tests were calculated.

Results: In the study period 142 patients were admitted to the hospital with complaints of diabetic foot infection. Of these patients, 100 (70.4%) were male, 42 (29.6%) were female and mean age of patients was 62.28±11.34 (35–88). Duration of ulcers were shorter than one week in 19 (13.4%), 1–4 weeks in 38 (26.8%) and longer than four weeks in 84 (59.2%) of patients. Osteomyelitis was diagnosed in 52 (36.6%) patients and 35 (67.3%) patients with ostemyelitis had ulcer for more than four weeks. For diagnosis of osteomyelitis, sensitivity, specificity, PPV and NPV of WBC, CRP, and ESR levels were summarised in the table.

Table. Sensitivity, specificity, PPV and NPV percentages of laboratory tests

Test	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Leucocytosis	57.6	54.4	42.2	69
ESR (higher than 20 mm/h)	94.2	8.8	37.4	72.7
ESR (higher than 75 mm/h)	40.3	75.5	48.8	68.6
CRP (higher than 5 mg/dL)	90.3	15.5	38.2	73.6
CRP (higher than 100 mg/dL)	55.7	78.8	60.4	75.5

Conclusions: ESR and CRP levels had very low specificities (8.8% for ESR and 15.5% for CRP) but their sensitivities were comparatively high (94.2% for ESR and 90.3% for CRP). When different levels of ESR (higher than 75 mm/h) and CRP (higher than 100 mg/dL) were taken in

to consideration we realised an elevation in their values. We concluded that none of these tests has high sensitivity and specificity alone. But for evaluation of a patient with diabetic foot ulcer, especially with longer duration, they should be considered together.

P1152 Treatment failure of cefepime therapy for febrile neutropenic patients with bacteraemia caused by cefepime susceptible ESBL-producing organisms

Y.E. Ha, Y.M. Wi, C.Y. Kang, H.S. Cheong, D.R. Chung, J.H. Song, K.R. Peck (Seoul, KR)

Objective: A retrospective analysis was carried out to evaluate treatment outcome of cefepime therapy for bacteraemia caused by apparently susceptible ESBL-producing *E. coli* and *K. pneumoniae*(ESBL-EK) in neutropenic patients.
Method: From January 2005 to December 2006, we selected the febrile neutropenic patients with bacteraemia due to ESBL-EK who were treated with cefepime. Antibiotic susceptibility testing was performed on using the modified broth microdilution method. For each isolates, MICs were determined for inoculum sizes of 105 and 107 cfu/ml. To characterise ESBLs, the TEM-, SHV-, and CTX-M-related genes from clinical isolates were amplified by PCR.
Result: Fifty-eight patients with ESBL *E. coli* and thirty-one patients with ESBL *K. pneumoniae* bacteraemia were identified during the study period. Of these patients, there were fifteen febrile neutropenic patients using cefepime. As a result, six eligible patients were included.

Table 1. Clinical outcomes of 6 febrile neutropenic patients with ESBL-producing *K. pneumoniae* and *E. coli* bacteraemia treated empirically with cefepime to which the causative organisms were susceptible in vitro

Age/Sex	Underlying disease	Site of infection	Organisms	Responsible ESBL	Initial antibiotic regimen	Cefepime MIC (μg/ml) 10^6 cfu/ml	10^7 cfu/ml	Treatment outcome
52/F	Multiple myeloma	Urinary tract	*E. coli*	TEM	FEP	8	>256	Cure: complete response to initial antimicrobial therapy
70/F	Lymphoma	Unknown	*K. pneumoniae*	TEM	FEP, VAN	8	>256	Failure: persistent fever and bacteraemia after 3 days; changed to imipenem, but infected by MRSA on 9th day and died on 30th day of treatment.
40/M	Aplastic anaemia	Biliary tract	*E. coli*	TEM	FEP	8	>256	Failure: persistent fever and bacteraemia after 3 days; changed to meropenem without biliary intervention and died on 20th day of treatment.
41/M	Aplastic anaemia	Lung	*K. pneumoniae*	TEM	FEP	2	128	Failure: persistent fever and bacteraemia after 3 days; changed to imipenem and transferred to a hospice hospital on 15th day.
45/F	Lymphoma	Perianal abscess	*E. coli*	TEM	FEP, VAN, MTZ	2	128	Failure: persistent fever after 3 days; changed to imipenem and vancomycin, but died on 20th day of treatment.
70/M	Lymphoma	Unknown	*K. pneumoniae*	CTX-M	FEP	2	128	Failure: persistent fever and bacteraemia after 3 days; changed to imipenem, but infected by *Candida* on 5th day and died on 24th day of treatment.

Abbreviations: FEP: cefepime; VAN: vancomycin; MTZ: metronidazole; GI: gastrointestinal.

Conclusions: The outcome of cefepime therapy for bacteraemia due to ESBL-EK was poor, even in apparently susceptible organisms. Thus, cefepime might not provide an optimal therapeutic option in ESBL-EK infections, even in apparently susceptible isolates.

Molecular diagnostics of atypical bacteria

P1153 Association of *Ureaplasma urealyticum* infection with varicocele-related infertility

S. Najar Peerayeh, H. Zeighami, R. Salman Yazdi, M. Razeghi (Tehran, IR)

Introduction: Varicocele is a physical abnormality present in 15% of healthy men and 40% of men being treated in infertility clinics. The association between reduced male fertility and varicocele likely is related to semen abnormalities, decreased testicular volume and decline in Leydig's cell function. On the other hand, the presence of *U. urealyticum* in semen is also related to a decrease in sperm density, motility and morphology. Thus in this study, the prevalence of *U. urealyticum* colonisation in infertile patients with and without varicocele compared with healthy men and their negatives effects on semen parameters were determined.
Methods: Semen samples were obtained from infertile patients with or without varicocele and healthy control and were subjected to the routine semen analysis and PCR. DNA was extracted by Cadieux method, and analysed by PCR protocol with species-specific primers for *U. urealyticum* (urease gene).
Results: *U. urealyticum* was detected by PCR in 23 of 146 (15.75%) semen specimens from infertile patients and in 3 of 100 (3%) healthy men ($P < 0.001$). Infertile patients with varicocele had higher *U. urealyticum* colonisation [17/81(20.98%)] than those without varicocele [6/65(9.23%), P = 0.086] or healthy controls [3/100 (3%), $P < 0.001$].The percentage of sperm cells with motility, volume of semen fluid, concentration of sperm cells, and sperm cell with normal morphology were significantly decreased in infertile men ($P < 0.001$). In the group of varicocele patients with PCR positive for *U. urealyticum* the volume, count and morphology of semen samples were lower than in the varicocele patients with PCR negative results, but the differences were not significant ($P > 0.05$).
Conclusion: The results indicate that *U. urealyticum* colonisation may be additional negative factor influencing varicocele status and worsening the reproductive potential.

P1154 The prevalence of *Mycoplasma genitalium* in the Netherlands

L. Smeets, D. Maljers, J. Merks, C. Bakker, J. Middelburg, S. Bruisten (Delft, Amsterdam, NL)

Introduction: *Mycoplasma genitalium* (Mg) has been recognised as the third-most important cause of urethritis, after *Chlamydia trachomatis* (Ct) and *N. gonorrhoeae* (Ng), and may also play a role in cervicitis and pelvic-inflammatory disease (PID). The goal of this study is to determine the prevalence of Mg in different populations in the Netherlands.
Methods: Study populations: (A) 163 men with non-specific complaints of urethritis (NSU) that visited the anonymous sexual transmitted infection (STI) clinic of the Health Service Amsterdam, hereafter: "high-risk population". (B) patients that visited their general practitioner (GP) in the Delft/Westland area, hereafter: "low-risk population". This population was divided in subgroups based upon information provided by their GP. (1) men with urethritis, (2) women with pelvic inflammatory disease (PID)/cervicitis, (3) men and women asking for STD-screening. Diagnostic STI-samples (urethral swabs, urine and vaginal swabs) were anonymised for this study.
Methods: Mg was detected by real-time PCR based on conserved regions of the MgPa adhesin gene as described (Jensen et al. JCM 2004 42 683–92). Positive controls were kindly provided by JS Jensen. Ct was tested by PCR, Ng was tested by PCR and/or by culture.
Results: The results are shown in the table.

Table: the prevalence of *M. genitalium* compared to *C. trachomatis* and *N. gonorrhoeae* in the different patient groups.

	M. genitalium	*C. trachomatis*	*N. gonorrhoeae*
(A) High-risk population			
♂ urethritis NSU (163)	18 (11%)	50 (30%)	1 (0.6%)
(B) Low-risk population			
♂ urethritis (240)	20 (8.3%)	46 (19%)	8 (3.3%)
♀ PID/cervicitis (304)	5 (1.6%)	10 (3.3%)	1 (0.3%)
♂ "STD screening" (315)	10 (3.2%)	26 (8.3%)	5 (1.6%)
♀ "STD screening" (297)	8 (2.7%)	14 (4.7%)	1 (0.3%)

Of the high-risk population, 18 urine samples (11%) were found positive for Mg. Of these 18, one was HIV+, one patient was also acutely

infected with HBV. Five (27%) were positive for Ct, this was similar as in the total group (30%) One Ct was an LGV-type and another was also positive for Ng. Of the low-risk population, 20 (8.3%) men with urethritis were positive by Mg PCR. A lower prevalence was found among asymptomatic men (10; 3.2%), women diagnosed with PID or cervicitis (5; 1.6%) and asyptomatic women (8, 2.7%). No double infections were found in these groups. Mg was not detected in the control samples.

Discussion: Our data confirm the previously described correlation between the presence of Mg and urethritis. The co-infections in group A underline the high-risk category these men belong to. Women with symptoms have a similarly low prevalence as women without symptoms. In each of our subgroups, the prevalence of Mg was lower than of Ct, but higher than of Ng. Routine testing for Mg is useful for urethritis in males, but less so for women in an outpatient setting.

P1155 Evaluation of four nucleic acid amplification tests for *Chlamydia trachomatis* in urine specimens

L. Dean, K. Perry, E. Arnold, A. Charlett, S. Alexander, C. Ison, G. Underhill, A. Lloyd, C. Walker, H. Mallinson, S. Scragg, C. Carder, G. Ridgeway (London, Portsmouth, Liverpool, UK)

Chlamydia trachomatis is the most common sexually transmitted infection in the United Kingdom and nucleic acid amplification testing (NAAT) is the method of choice for diagnosis. Our aim was to assess the diagnostic sensitivity and specificity of four commercially available NAATs: Roche COBAS AMPLICOR, BD ProbeTec ET, Gen-Probe Aptima 2 Combo and Artus *C. trachomatis* Plus real-time PCR. The tests were evaluated against the same specimen panel with the same reference standard using a statistically valid number of specimens to provide a confident measure of sensitivity and specificity.

The evaluation panel consisted of 2374 male and female urine specimens. Of these 1519 were negative and 595 were positive. Samples were assessed following the UK testing algorithm for *C. trachomatis* that demands retesting of all initially positive samples and defines a positive sample as one that is reproducibly positive by the test in use.

An imperfect standard was constructed using three of the four assays under evaluation (COBAS AMPLICOR, ProbeTec ET and Aptima 2 Combo). To help assess any resulting bias five different methods (denoted as options 1–5) were used to construct the standard, showing how much the sensitivity and specificity could vary. Sensitivity and specificity were assessed against the status defined by each of the options. The data below represents results from one of the five options used to define specimen status. Differences in sensitivity and specificity between each of the options were not statistically significant.

Overall, the most sensitive assay was the APTIMA 2 Combo (99.4%), followed by the COBAS AMPLICOR (96.85%), the ProbeTec ET (95.81%) and the Artus real-time PCR (94.9%). When data was analysed by sex, all assays were found to have a higher sensitivity with male urine specimens than with female urine specimens.

The ProbeTec ET assay had the greatest specificity (99.81%) followed by the COBAS AMPLICOR (98.17%), the APTIMA 2 Combo (98.15%) and the Artus real-time PCR (97.9%).

The assays evaluated achieved good sensitivity and specificity. However, we have demonstrated that there are statistically significant differences in the sensitivity of these assays. It is of note that the most sensitive test (APTIMA 2 Combo) was the least specific (99.37%) while the least sensitive (ProbeTec ET) was the most specific. This finding demonstrates the interrelationship between sensitivity and specificity inherent in all these test platforms.

P1156 Identification and characterisation of new immunoreactive proteins of *Chlamydia trachomatis*

V. Forsbach-Birk, K.-I. Pfrepper, U. Simnacher, E. Soutschek, A. Essig (Ulm, Neuried, DE)

Objective: The serological detection of chronic urogenital infections caused by *Chlamydia trachomatis* is complicated by the lack of known immunoreactive antigens that do not share crossreacting epitopes with other *Chlamydia* species pathogenic to humans. For that reason we aimed to identify and characterise new so far unidentified immunoreactive antigens of *Chlamydia trachomatis*.

Methods: Purified elementary bodies were analysed by 2D-PAGE followed by Western blotting with sera from patients with proven pelvic inflammatory disease caused by *Chlamydia trachomatis*. Unknown antigens being identified by that method were cloned in *Escherichia coli* and characterised with panels of sera from patients with chronic urogenital infections with *Chlamydia trachomatis* as well as from healthy blood donors with positive MIF tritres for *Chlamydia trachomatis* or *Chlamydophila pneumoniae*.

Results: Besides known immunoreactive antigens like MOMP, OMP2, and HSP60 a number of new immunoreactive antigens of *Chlamydia trachomatis* were identified by 2D-PAGE and Western blotting with the defined sera. The newly identified antigens were produced recombinantly and proved to be immunoreactive. Their reactivity to the defined serum panels was compared to known immunoreactive antigens. The data revealed a high sensitivity of the newly identified antigens. They showed lower crossreactivitiy to *Chlamydophila pneumoniae* and a much better discrimination between patients with chronic urogenital infections caused by *Chlamydia trachomatis* and seropositive but healthy blood donors.

Conclusion: The newly identified antigens need to be further characterised but might be of importance in order to improve current serological approches for the diagnostics of *Chlamydia trachomatis* infections.

P1157 A new real-time quantitative PCR to detect Coxiella burnetii DNA

G. Greub, J. Rolain, J. Bille, D. Raoult, K. Jaton (Lausanne, CH; Marseille, FR)

Objectives: Q fever is a worldwide zoonosis due to Coxiella burnetii. The clinical presentation may be acute (pneumonia and/or hepatitis) or chronic (most commonly endocarditis). Diagnosis mainly relies on serology. However, PCR was also shown to be useful for the diagnosis of both acute and chronic Q fever.

Methods: A quantitative PCR to be used on ABI Prism 7900 Sequence System (Applied Biosystem) was developed. DNA was extracted with Magna-PureR (Roche) and the PCR was performed using 5 ml DNA and 15 ml PCR mixture. Primers and probe were selected from highly conserved sequence of the ompA gene. Development of the quantitative PCR was done using DNA extracted from a valvular sample. The quantitative PCR was then blindly evaluated with 183 DNA samples (31 biopsies, 110 sera/EDTA blood and 42 urines) provided from the “Unité des Rickettsies” (Marseille). Among them, 41 samples taken from patients with a positive Coxiella serology were positive with the Marseille home-made nested LC-PCR.

Results: Using eubacterial 16S rRNA PCR and the new quantitative PCR, the positive control was still positive when diluted 1/1,000 and 1/100,000, respectively. With the quantitative PCR, no signal was detected in presence of bacterial DNA of other bacterial species potentially present in various non-sterile clinical samples. When tested blindly on 183 samples, the specificity of the quantitative PCR was 100% (142/142) and the sensitivity was 71% (29/41). The sensitivity was 88% (7/8) on biopsies samples, 69% (20/29) on sera/EDTA blood, and only 50% on urines (2/4).

Conclusion: This quantitative PCR is a specific method that exhibits an analytical sensitivity about one hundred fold higher than eubacterial PCR. When tested blindly, the quantitative PCR exhibited a specificity of 100%, a good sensitivity on valvular samples taken from patients with Q fever endocarditis or vascular infection, and a fair sensitivity on serum samples from patients with chronic Q fever.

P1158 Antimicrobial resistance of *Mycoplasma hominis* and *Ureaplasma urealyticum* among women with vaginal discharge

E. Draghijeva, P. Egbase (Kuwait, KW)

Objectives: The aim of study was to isolate *Mycoplasma hominis* (Mh) and *Ureaplasma urealyticum* (Uu) and determine the antimicrobial resistance in cervicovaginal samples of women who had complaints of vaginal discharge using Mycoplasma IST2 (Biomerieux).
Methods: There were 151 patients with vaginal discharge included in the study: 59 pregnant and 92 non-pregnant. Vaginal samples were taken from endocervical region after ecocervical mucus had been swabbed clean. Mycoplasma IST2 used for investigation of Mh and Uu provided information about the presence or absence of Mh and Uu and also their antimicrobial susceptibility to doxycycline, josamycin, ofloxacin, erythromycin, tetracycline, ciprofloxacin, azithromycin, clarythromycin and pristinamycin.
Results: Uu has been isolated in 9 (15.2%) pregnant women, while Mh has been isolated in 1 (1.7%) of them. Uu and Mh have been both isolated in 49 (83.1%) of these patients. While of 92 non-pregnantwomen, respectively 10%, 6% and 84% have been isolated.
The Uu and Mh has been shown the lowest sensitivity to ciprofloxacin with 6 (22.2%) of isolates being resistant. The mixt Mh/Uu isolates have shown high sensitivity on Erythromycin and Clarythromycin with 83% and 81.5% respectively being sensaitive.
Conclusions: A higher prevalence of Uu/Mh is noted in the vaginal swabs as well as higher resistance in the quinolones. Low level resistance to microlides and pristinamycin must be taken into account in the empirical teatment strategy.

Antibiotic susceptibility studies in Gram-negatives

P1159 Increased antimicrobial susceptibility profiles among polymyxin-B-resistant *Acinetobacter baumannii* clinical isolates

R. Mendes, T. Fritsche, H. Sader, R. Jones (North Liberty, US)

Objective: Infections caused by multidrug-resistant (MDR) *A. baumannii* have become a major treatment challenge, requiring the re-introduction of polymyxins into clinical practice. Given this situation, the emergence of polymyxin B (PB) resistance (R) is expected. Recently, increased antimicrobial susceptibility (S) among in vitro passaging of colistin-R *A. baumannii* isolates was observed when compared with the parent colistin-S strains. The aim of this study was to compare the S profile between PB-R and PB-S *A. baumannii* patient isolates submitted to the SENTRY Antimicrobial Surveillance Program.
Methods: A collection of 5,561 *A. baumannii* clinical isolates was S tested by the CLSI broth microdilution method and the S rates of 24 epidemiologically unrelated PB-R isolates were compared to those of PB-S isolates. S rates were analysed by chi^2 test using the Epi Info™ Version 3.4.1 software package. P values <0.05 were considered to be statistically significant.
Results: The majority of the antimicrobials tested showed limited spectrums of activity (S rates, ⩽55.4%) against the PB-S *A. baumannii* group, except for imipenem (73.2%), meropenem (76.5%) and some tetracyclines. Doxycycline, minocycline and tigecycline showed the highest S rates 74.7, 91.7 and 97.0%, respectively. Overall, the polymyxin-R group showed a higher S rate for the vast majority of antimicrobials tested. This shift was not observed among those antimicrobial agents with higher activity against the PB-S group (i.e. carbapenems and tetracyclines). Statistically significant differences were observed among most drugs showing lower activity, including ampicillin/sulbactam (S rate 3× higher), aztreonam (4×), cefoxitin (20×), ceftriaxone (2×) and cefuroxime (8×). Tigecycline was highly active regardless the susceptibility to PB.
Conclusions: PB-R *A. baumannii* clinical isolates showed higher S rates when compared to PB-S isolates for the majority of antimicrobials tested. These findings suggest that possible lipopolysaccharide modifications among PB-R bacterial cells may increase permeability to the antimicrobial agents. These data may provide additional insights for combination therapeutic options and also for possible novel antimicrobial agents in drug development.

P1160 Evaluation of tigecycline resistance in a tertiary hospital

H. Moraitou, M. Makarona, I. Galani, V. Spyropoulos, I. Mamai, F. Havouti, D. Kalikantzaros, S. Kanavaki (Athens, GR)

Objectives: Tigecycline (TG), has a wide spectrum of antimicrobial activity, and has been recently used against multi-drug resistant organisms. The aim of this study was to evaluate resistance levels to tigecycline, since this antimicrobial agent has been administered in our Hospital, in multidrug-resistant (MDR) *Acinetobacter baumannii* and *Klebsiella pneumoniae* strains isolated from ICU and non-ICU patients.
Methods: From January to September 2007, 220 unique patient multidrug-resistant *A. baumannii* and 42 *K. pneumoniae* strains were isolated from different clinical samples, both in ICU and non-ICU patients. The isolates expressed resistance to aminoglycosides, fluoroquinolones, broad-spectrum cephalosporins and carbapenems. The strains were identified using the VITEK 2 automated system (Biomerieux, France). Susceptibility to minocycline was tested by the VITEK 2 and to TG by both Kirby-Bauer (zone breakpoints for 15 μg TG discs: *Acinetobacter* spp. and Enterobacteriaceae, S ⩾ 24 mm, R ⩽ 19 mm;) and E-test (MIC(90), 2 μg/ml). Clonal relatedness of all TG-resistant strains was determined by Rep-PCR.
Results: All MDR *A. baumannii* and *K. pneumoniae* were resistant to minocycline. Overall TG-resistance rates were 10.9% (24/220) for MDR *A. baumannii* strains and 11.9% (5/42) for *K. pneumoniae* strains isolated both from ICU and non-ICU patients. ICU resistance rates were 20.3% (14/69) for *A. baumannii* and 12.0% (3/25) for *K. pneumoniae*, while non-ICU resistance rates were 6.6% (10/151) and 11.7% (2/17) respectively. In addition all TG-resistant *K. pneumoniae* isolates expressed carbapenemase activity, with a positive imipenem/EDTA test. Rep-PCR revealed high relatedness of all *A. baumannii*, regardless the origin of isolation, but *K. pneumoniae* strains were not clonally related.
Conclusion: The TG-resistance rates in MDR *A. baumannii* are similar both in ICU and non-ICU patients, while *K. pneumoniae* shows higher resistance rates in ICU than in non-ICU patients. Molecular typing indicates dissemination of related resistant *A. baumannii* strains throughout the hospital. However, tigecycline remains a potent and effective antimicrobial agent for use in hospital-acquired infections.

P1161 Analysis of tigecycline activity against Enterobacteriaceae and *Acinetobacter* spp. based on patient location and clinical specimen source in Europe

D. Draghi, C. Pillar, C. Thornsberry, M. Dowzicky, D. Sahm (Herndon, Collegeville, US)

Objective: The propensity for Enterobacteriaceae (EN) and *Acinetobacter* spp. (AC) to develop antimicrobial resistance can vary with the patient location (PL) and the type of infection (as suggested by the specimen source [SS]) from where the isolates were obtained. Therefore, to investigate trends in tigecycline (TIG) activity against EN and AC, analysis of TIG activity was stratified according to PL and SS using data collected during 2006 to 2007.
Methods: Isolates were collected from locations broadly dispersed across Europe (EU; including 11 countries) and were tested centrally using broth microdilution (CLSI M7-A7). TIG activity was analysed according to PL (outpatient [OP], intensive-care unit [ICU], and inpatient non-ICU [IP]) and SS (blood [BL], respiratory [RP], skin and skin structure [SST], and urine [UR]). EN EUCAST breakpoints (BPs) were applied to all TIG results (AC EUCAST BPs do not currently exist).
Results: See the table.
Conclusion: For EN, slight variations in %S for TIG were observed among the evaluated PL and SS; however, all populations were >95% S

to TIG. For AC, the MIC90 remained ⩽2 mg/L and the %S rates for TIG varied by 10% based on the population studied. All populations of AC were >83% S to TIG, including the ICU population which is associated with reduced susceptibility. The ability of these organisms to develop resistance requires that surveillance be on-going.

Org	Category	TIG Total n	MIC range	MIC_{90}	% Susceptible (S)
EN	OP	87	0.06–2	1	98.9
	IP	497	0.06–8	1	97.6
	ICU	289	0.06–4	1	95.5
	BL	323	0.06–8	1	97.2
	RP	275	0.06–4	1	96.4
	UR	50	0.06–2	1	98

P1162 In vitro activities of several antimicrobials alone or in combination against MDR *Acinetobacter baumannii* isolated from intensive care unit

F. López-Fabal, F. González-Romo, E. Culebras, J.J. Picazo (Madrid, ES)

Objective: *Acinetobacter baumannii* has become an important hospital-acquired pathogen. Carbapenems have been the agents of choice for serious *Acinetobacter* infections, but unfortunately, outbreaks of *A. baumannii* resistant to all antimicrobials except the polymyxins, have been reported. This fact creates demand on the application of some combinations of older antimicrobials on that species. The objective of this study was to assess the in vitro activity of 27 antibiotics against MDR strains of *A. baumannii* isolated from ICU, and determine whether combinations of colistin with another antibiotics act synergistically against these strains.
Methods: 32 non-repetitive isolates of *A. baumannii* were included in the study. Isolates were recovered from 21–12–2006 to 18–2–2007. Antibiotic susceptibility testing was determined by the broth dilution method according to the CLSI recomendations.
Etest with imipenem and imipenem plus EDTA were used to check metallo-β-lactamase (MBL) production. We also used cefotaxime (CT)/ cefotaxime + clavulanic acid (CTL) and cefepime (PM)/ cefepime + clavulanic acid (PML) E-test® for testing ESBL production in MDR *A. baumannii* isolates.
Four strains of *A. baumannii* were selected for the synergy study. Levels of synergistic activity for colistin combined with doxycicline, rifampicin, imipenem, meropenem and tigecycline were evaluated using the checkerboard method.
Results: All the isolates showed a high level of resistance to all β-lactam antibiotics tested. With the exception of colistin (0% of resistance) there were no antibiotics with good activity against these isolates. Of the other antibiotics tested, tigecycline shows the best activity with 1.5 mg/L of CMI90 value. MBL and ESBL were present in 32 and 0 isolates respectively. All the isolates showed the same susceptibility results, suggesting an outbreak presence.
The results of the checkerboard synergy analysis for MDR strains *A. baumannii* shown partial synergy or indifferent results.
Conclusions:
1. Susceptibility pattern revealed presence of MDR *A. baumannii* outbreak in ICU.
2. Metallo-β-lactamases were responsible of carbapenems resistance.
3. In studies of synergy, the effect of the combination treatment is unclear, although the possibility of a beneficial effect cannot be excluded
4. Tigecycline and colistin seem like the best option to treat these multirresistant bacteria.

P1163 Tigecycline activity against geographically diverse *Acinetobacter* spp. displaying multidrug-resistant phenotypes across Europe

C. Thornsberry, D. Draghi, C. Pillar, M. Dowzicky, D. Sahm (Herndon, Collegeville, US)

Objective: *Acinetobacter* (AC) is generally a nosocomial pathogen. There are several risk factors among patients that can be associated with increased infection of this organism such as extremely ill patients on a ventilator, those with a prolonged hospital stay, or those with open wounds. In 2006, tigecycline (TIG) was approved in Europe (EU) for treatment of complicated skin and skin structure infections and complicated intra-abdominal infections.
Methods: In total, 104 AC isolates were obtained from 28 hospitals in eleven countries across EU during 2006 to 2007. Isolates were tested centrally by broth microdilution (CLSI M7-A7). TIG activity was analysed according to susceptible (S), non-susceptible (NS), and multidrug phenotypes [MDR; resistance to ⩾3 agents including cefepime (FEP), ciprofloxacin (CIP), gentamicin (GEN), imipenem (IMI), minocycline (MIN), and piperacillin-tazobactam (PTZ)]. Enterobacteriaceae EUCAST breakpoints (BPs) were applied to all TIG results (BPs do not currently exist for AC). CLSI (M100-S17) BPs were used to interpret all comparators (where applicable).
Results: The most common MDR phenotype was 3-drug R with concurrent R to CIP, GEN, and PTZ (12.5% of all isolates surveyed) followed by 5-drug R with concurrent R to FEP, CIP, GEN, IMI, and PTZ (9.6% of all isolates surveyed).

Org	Total N	TIG MIC (mg/L)		%S
		Range	MIC_{90}	
All	104	0.06–4	2	89.4
CIP S	38	0.06–1	1	100
CIP NS	66	0.12–4	2	83.3
FEP S	58	0.06–2	1	96.6
FEP NS	46	0.25–4	2	80.4
IMI S	77	0.06–2	1	92.2
IMI NS	27	0.12–4	2	81.5
Non-MDR	58	0.06–1	1	100
MDR	46	0.25–4	2	76.1

Conclusions: TIG maintained potent in vitro activity against AC. The TIG MIC90 ranged from 1 to 2 mg/L, regardless of resistance or MDR phenotype. Due to the resistance associated with AC, it is imperative to monitor the susceptibility patterns of this organism against new agents such as TIG.

P1164 Evolution of the antimicrobial resistance of *A. baumannii* strains isolated at an intensive care unit

E. Chinou, P. Ntavlouros, A. Georgouli, H. Skouteli, P. Giannakakos, P. Golemati (Athens, GR)

Multiresistant *A. baumannii* including resistance to carbapenems is a common cause of severe nosocomial infections.
Objectives: to evaluate the frequency and the antimicrobial resistance evolution of *A. baumannii* isolated from ICU patients during a two years period.
Methods: From July 1st 2005 to June 30th 2007 strains of *A. baumannii* were isolated from different clinical samples coming from patients

hospitalised in the seven beds multidisciplinary ICU of our hospital. The strains were identified with the biochemical galleries (API NE) and their susceptibility to the antimicrobial agents evaluated by the disk diffusion method and E-test for imipenem, colistin and tigecycline according to CLSI recommendations.

Results: 335 strains of *A. baumannii* were isolated from 93 patients in ICU. 37 of the above group patients developed *A. baumannii* bacteraemia. All *A. baumannii* strains were sensitive to colistine with MIC90 0.25 mgr/lt and to tigecycline with MIC90 1 mgr/lit. The susceptibility rate(%) to Amikacin(A), Ciprofloxacin(C), Ceftazidime(CAZ) and Imipenem(I) decreased noticeably as follow: A: from 16 to 5, C: from 17 to 0, CAZ: from 16 to 5 and I: from 67 to 23.

Conclusion: The *A. baumannii* strains isolated in ICU patients during the period 2005–2007 presented a high level of antimicrobial resistance which was often associated to a resistance to at least 3 antimicrobial agents. In some cases the strains were totally resistant and sensitive only to colistin and tigecycline. The most notable resistance was to Imipenem which increased from 33% to 77%. Infection control measures must be constant and intense to eliminate the diffusion of these strains.

P1165 In vitro testing of carbapenem-resistant *Acinetobacter baumannii* to colistin (polymyxin E)

I. Goic-Barisic, B. Bedenic, M. Tonkic, A. Novak, V. Punda-Polic (Split, Zagreb, HR)

Objectives: Carbapenem-resistant strains of *A. baumannii* have been reported in almost all European counties. Thus more toxic agents such as polymyxins have been used as alternative therapeutic drugs against multidrug-resistant *Acinetobacter baumannii* infections. At present there is no agreement about how to look for colistin resistance. The Societe Francaise de Microbiologie uses a cut off of 2 mg/l by broth microdilution testing, whereas the British Society for Antimicrobial Chemotherapy sets a cut off of 4 mg/l or less as sensitive, and 8 mg/l or more as resistant. There are no US standards for measuring disk diffusion sensitivity to polymyxin so far whereas CLSI (formerly NCCLS) documents do currently provide interpretative criteria for minimal inhibitory concentration by broth microdilution testing of polymyxins in *Acinetobacter* spp.

Methods: Twenty-nine non-repetitive *A. baumannii* isolates with carbapenem resistance profile were obtained from patients hospitalised at different Intensive Care Units inside Clinical Hospital Centre Split during this year and tested by broth microdilution to colistin (polymyxin E). Isolates were recovered from blood cultures, urine samples and bronchial secretions. Although disk diffusion sensitivity to polymyxin is not standardised, the diameter of inhibition zone to colistin (10 μg) was measured.

Results: Out of total number of tested strains, twenty-two isolates (22/29) displayed minimum inhibitory concentration of 2 mg/l and six (6/29) isolates MIC of 4 mg/l. One isolate displayed MIC of 128 mg/l to polymyxin.

All isolates of *A. baumannii* displayed intermediate or resistant profile to imipenem (MICs 8–16 mg/L) and meropenem (MICs 8–64 mg/L). The diameter of inhibition zone to colistin by disk diffusion test was larger than 11 mm for all strains.

Conclusion: According to currently available criteria for interpretative reading for broth microdilution testing of polymixins in *Acinetobacter* spp., we found variability in susceptibility of our isolates to polymyxin. Against CLSI standard, most of our isolates (22/29) displayed susceptibility to polymyxin showing MIC values of 2 mg/l or less as sensitive. Regarding the results obtained with a disk diffusion test, we would recommend the confirmation by a dilution method, especially in the case of serious systemic infections.

P1166 High rate of non-susceptibility to tigecycline in pan-resistant *Acinetobacter* spp. from Portugal

S. Quinteira, F. Grosso, L. Peixe (Porto, PT)

Objectives: Tigecycline has been described as an alternative therapeutic agent against *Acinetobacter* spp. infections, within a global increase of multidrug-resistance context. In our country multidrug-resistant *Acinetobacter* spp. isolates have been increasingly recovered, complicating the patient's clinical outcomes. In this study we evaluated the in vitro activity of tigecycline against pan-resistant *Acinetobacter* spp. (including resistance to imipenem) isolated in Portuguese hospitals.

Methods: 250 imipenem-resistant *Acinetobacter* spp. isolates were collected between 2001 and 2007, from a variety of clinical specimens of different patients attending distinct wards in five hospitals. Isolates were identified by API32GN and by sequencing the 16S rRNA gene. MICs of tigecycline were determined by agar dilution method, according to CLSI guidelines, and a susceptible breakpoint of $\leqslant$2 mg/L. PFGE (ApaI restriction enzyme) was performed. Oxacilinase genes (OXA-23, 40, 51, and 58) were sought by a multiplex PCR.

Results: From the 250 isolates studied, 248 were identified as *A. baumannii* and 2 as *A. haemolyticus*. Resistance to several β-lactams (including imipenem) and variable susceptibility to aztreonam, ceftazidime, meropenem, amikacin and tobramycin was a common feature of these isolates. MICs for tigecycline ranged from 0.25–32 mg/L, and MIC50 and MIC90 values were 4 and 8 mg/L, respectively. Only 55 (including the two A. haemolitycus) of 250 *Acinetobacter* spp. isolates (22%) were susceptible to tigecycline. Tigecycline resistance (MIC $\geqslant$8 mg/L) was observed in 67 isolates (26.8%), belonging to the PFGE patterns disseminated within different hospitals. Among these isolates, 4 presented a MIC of 16 mg/L and 7 a MIC of 32 mg/L. Noteworthy, 128 isolates were classified as intermediate to tigecycline (MIC of 4 mg/L). All OXA-23 producing isolates presented MICs to tigecycline $\geqslant$8 mg/L.

Conclusion: High rate of non-susceptibility (78%) to tigecycline, the newest antimicrobial agent for *Acinetobacter* spp. was observed, further compromising the treatment of infections by an aetiological agent currently considered the most troublesome nosocomial pathogen.

P1167 In vitro bactericidal effect of imipenem, meropenem and piperacillin/tazobactam against β-lactam-resistant *Pseudomonas aeruginosa* strains and ESBL-producing Enterobacteriaceae

C. Muller-Serieys, A. Merens, J.D. Cavallo, C. Laussucq, M.L. Joly-Guillou, M. Roussel-Delvallez (Paris, Angers, Lille, FR)

Objectives: In France, the spread of acquired multiresistance in *P. aeruginosa* (Pa) and Enterobacteriaceae (Eb) has become a great concern. Infections caused by these bacteria require early treatment with bactericidal antibiotics. Carbapenems are often the last resort alternative. The goal of this study was to compare the in vitro kill-rates of imipenem (IPM), meropenem (MPM) and piperacillin/tazobactam (PTZ) against 7 Pa strains with different β-lactam resistance mechanisms and 4 ESBL-producing Eb.

Material and Methods: The standard time-kill method was used to investigate the bactericidal activity of IPM, MPM and PTZ. The concentrations tested were the breakpoints defined by EUCAST for Eb (2 and 8 mg/L for IPM and MPM) and for Pa (4 and 8 mg/L for IPM, 2 and 8 mg/L for MPM). For PTZ: 16/4 mg/L was used for Pa and 8/4 mg/L for Eb. The following strains were studied: (i) *P. aeruginosa* ATCC 27853, *E. coli* ATCC 25922 as reference strains, (ii) seven Pa: efflux (overexpression of MexAB/OprM pump), mutation of OprD2, carbenicillinase PSE-1, extended-spectrum β-lactamase PER-1, carbapenemases IMP-1 and VIM-2 and overexpressed constitutive cephalosporinase, (iii) four ESBL Eb: *K. pneumoniae* CTX-1 and SHV-2, *E. aerogenes* TEM-24, *E. coli* CTX-M15. Bactericidal effect was defined by a 3 Log10 CFU/mL decrease in viable counts.

Results: A bactericidal effect was obtained at 6–8 hours for IPM and MPM at 8 mg/L for all Pa strains except for those with

acquired resistance mechanisms to carbapenems (mutation of OprD2 and carbapenemases). The use of lower concentrations of IPM (4 mg/L) or MPM (2 mg/L) resulted in a decrease or abolition of bactericidal effect and a frequent regrowth after 8 h. PTZ was bactericidal only for the strain displaying efflux resistance mechanism. For ESBL-producing Eb, both carbapenems were bactericidal against all strains in 4–8 hours at 2 mg/L and 8 mg/L. MEM was more rapidly bactericidal than IPM (killing activity at 2 hours for 3 strains/4 at 8 mg/L). No regrowth was observed. PTZ was not bactericidal and only a 2 Log10 decrease of inoculum was obtained.
Conclusion: IPM and MPM achieved a rapid killing activity against the most prevalent ESBL Enterobacteriaceae in France and provided a bactericidal activity at 8 mg/L against all *P. aeruginosa* strains without OprD2 mutation or carbapenemase.

P1168 In vitro activity of doripenem relative to meropenem and imipenem against Enterobacteriaceae and *P. aeruginosa* isolates from Europe (2006–2007)

M. Torres, D. Draghi, N. Brown, C. Thornsberry, D. Sahm, C. Pillar (Herndon, US)

Objective: Carbapenems are widely used to treat infections involving resistant Gram-negative pathogens due to their potent activity against extended β-lactamase producing enteric bacilli and *P. aeruginosa* (PA). Doripenem (DOR), a 1-beta-methyl carbapenem, is approved to treat complicated urinary tract infections (cUTI) and intra-abdominal infections (IAI) in the US, and is currently undergoing regulatory review for the treatment of cUTI and IAI in Europe (EU), and nosocomial pneumonia both in the US and EU. This study examined the in vitro activity of DOR relative to other currently available carbapenems against Gram-negative pathogens recently isolated from EU.
Methods: During 2006 and 2007, Enterobacteriaceae (EN) and PA isolates from patient specimens were collected from 28 laboratories in 11 EU countries. All isolates were centrally tested by broth microdilution against DOR, imipenem (IPM), and meropenem (MER) at Eurofins Medinet, Inc. (CLSI; M7–A7). Data were interpreted according to CLSI M100-S17 for IPM and MER. For DOR, there are no CLSI approved breakpoints.
Results: By MIC50/90, DOR and MER were similar in activity against the tested isolates and were superior to IPM, regardless of CAZ susceptibility. The MICs of DOR and MER were lower than IPM against the EN and PA tested.

Org	Phenotype	Total n	DOR			IPM				MER			
			MIC (mg/L)			MIC (mg/L)				MIC (mg/L)			
			Mode	MIC_{50}	MIC_{90}	Mode	MIC_{50}	MIC_{90}	% S	Mode	MIC_{50}	MIC_{90}	% S
EN	All	1,912	0.03	0.03	0.25	0.25	0.25	2	99.8	0.03	0.03	0.12	100
	CAZ S	1,656	0.03	0.03	0.12	0.25	0.25	2	99.9	0.03	0.03	0.06	100
	CAZ NS	256	0.03	0.06	0.25	0.25	0.5	2	99.2	0.03	0.06	0.25	100
PA	All	533	0.25	0.5	8	2	2	32	76.0	0.25	0.5	8	85.0
	CAZ S	421	0.25	0.25	2	2	2	8	85.3	0.25	0.5	4	92.4
	CAZ NS	112	8	4	32	32	16	32	41.1	4	4	32	57.1

CAZ: ceftazidime; S: susceptible; NS: non-susceptible

Conclusion: EN from EU were highly susceptible (>99%) to the carbapenems tested, while susceptibility of PA ranged from 76% for IPM to 85% for MER, respectively. MICs of IPM were higher against both PA and EN than MICs of either DOR or MER, which were of similar activity by MIC50/90. The increasing prevalence of carbapenemases among EN and the high-level resistance commonly encountered among PA highlights the importance of continued surveillance of carbapenem activity against these organisms.

P1169 Ertapenem, imipenem, meropenem, tigecycline and fosfomycin activity against extended-spectrum β-lactamase producing Enterobacteriaceae in Austria

P. Apfalter, S. Zasmeta, A. Graf, A. Makristathis, A. Hirschl (Vienna, AT)

Objectives: Reported here are current Austrian susceptibility data on imipenem, meropenem, ertapenem, tigecycline and fosfomycin in ESBL-producing enterobacteriaceae.
Methods: ESBL production was detected by CLSI methods and an expanded double disk diffusion synergy test in 401 non-duplicate enterobacteriaceae (collection period June 04 to Dec 06). MICs were determined by means of Etest®. Strains not fully susceptible to one of the carbapenems were checked for the presence of metallo-β-lactamases by Etest® and typed by means of random amplification of polymorphic DNA (RAPD) and enterobacterial repetitive intergenic consensus (ERIC)-PCR.
Results: Strains were isolated from urine (44%), wounds (25%), the respiratory tract (14.5%), blood (4.5%), faeces (9%), and intravasal devices (2%). The table displays susceptibility data for the species *E. coli*, *Klebsiella* spp., and *Enterobacter* spp. No metallo-β-lactamases could be detected in strains with reduced carbapenem susceptibility. In addition, these strains were not clonally related.
Conclusions: Carbapenems were the most active antibiotics and *E. coli* was the most susceptible species tested. The lowest MICs were found for meropenem. According to CLSI and EUCAST, 3.4% and 10% strains were not fully susceptible to ertapenem, respectively. Thus, its susceptibility cannot reliably be predicted by testing imipenem or meropenem. Fosfomycin and tigecycline can be therapeutic options, but empiric susceptibility cannot be safely assumed and both agents should be tested.

	MIC_{90} (mg/L)	MIC range (mg/L)	Interpretative results in % according to CLSI/FDA (EUCAST) criteria		
			S	I	R

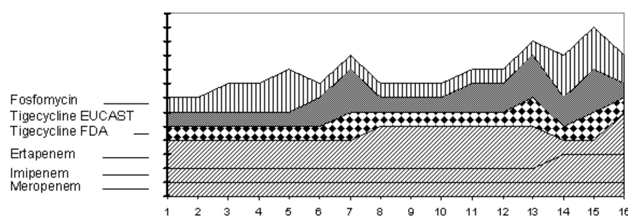
P1170 Fosfomycin and tigecycline activity in extended-spectrum β-lactamase producing Enterobacteriaceae with reduced carbapenem susceptibility

P. Apfalter, S. Zasmeta, A. Graf, W. Barousch, A. Makristathis, A. Hirschl (Vienna, AT)

Objective: A recent Austrian susceptibility study on 401 ESBL-producing enterobacteriaceae revealed 16 (4%) and 43 (10.7%) strains (CLSI vs. EUCAST breakpoints, respectively) not fully susceptible to at least one carbapenem, the first choice agents in empiric ESBL therapy. The aim of this study was to test the in vitro activity of the new agent tigecycline and fosfomycin, which could provide therapeutic alternatives.

Methods: ESBL production was detected by CLSI methods and an expanded double disk diffusion synergy test in 401 non-duplicate enterobacteriaceae collected between June 04 and Dec 06. MICs were determined by means of Etest®. Strains not fully susceptible to one of the carbapenems were checked for the presence of metallo-β-lactamases and typed by means of random amplification of polymorphic DNA and enterobacterial repetitive intergenic consensus PCR.
Results: Meropenem was the only carbapenem not affected by reduced sensitivity. No metallo-β-lactamase production was detected in strains with reduced sensitivity to ertapenem or imipenem. According to CLSI (EUCAST) 62.5% (76.7%), 81.2% (74.4%), and 56.2% (46.5%) strains were susceptible to fosfomycin, tigecycline (FDA) and tigecycline (EUCAST), respectively. The figure displays the 16 CLSI criteria applied strains and their susceptibility to tigecycline and fosfomycin (height on y-axis stands for interpretative category: 1 space = susceptible; 2 spaces = intermediate susceptible; 3 spaces = resistant).



Strains with reduced crabpenem sensitivity according to CLSI

Conclusions: Fosfomycin and tigecycline can be therapeutic options in infections caused by ESBL-producing enterobacteriaceae with reduced sensitivity to carbapenems, but empiric use cannot be recommended and testing is mandatory. Applying EUCAST breakpoints affected significantly resistance data for tigecycline, for which every second strain out of this panel would have to be categorised as not fully susceptible. The clinical significance of this phenomenon caused by breakpoints defined by various committees remains to be clarified.

P1171 In vitro activity of temocillin vs. extended-spectrum β-lactamase-producing Enterobacteriaceae from the UK

P. Khanna, D. Wareham (London, UK)

Objectives: Temocillin is a semisynthetic pencillin derivative of ticarcillin. The methoxy group in the 6-α-position confers loss of activity against Gram-positive cocci and anaerobic Gram-negative bacilli but excellent activity against the Enterobacteriaceae family. This modification increases stability to β-lactamases, including AmpC and ESBLs. Owing to the increasing incidence of infections caused by multi-drug resistant Gram-negative bacteria and also because of the limited number of clinically active drugs available against such organisms, we aimed to determine the in vitro activity of temocillin versus clinical isolates prevalent in the UK.
Methods: Strains were identified using chromogenic media and API 20E. Susceptibility to gentamicin, ampicillin, amoxicillin/clavulanate, cefuroxime, ciprofloxacin, piperacillin/tazobactam, amikacin, trimethoprim, aztreonam, ceftazidime, nitrofurantion and imipenem was determined using the BSAC disc diffusion method. Eighty-one isolates of Enterobacteriaceae were screened for ESBL production by using double disk synergy test with cefpodoxime and cefpodoxime clavulanate. ESBLs were characterised by multiplex PCR for genes encoding CTXM3-like, CTXM-14 like and SHV-like β;-lactamases. Minimum inhibitory concentrations of Temocillin were determined by agar dilution using isosensitest agar.
Results: Eighty-one urinary isolates were tested. All isolates were resistant to cephalexin and ampicillin. 82.5% were also resistant to trimethoprim and 33.3% to nitrofurantoin, used commonly as first line agents for uncomplicated urinary tract infections. MICs to Temocillin ranged from 8–128 mg/L with an MIC50 of 8 and an MIC90 of 32 mg/L. The most common β-lactamases were CTX-M3 lilke (85.5%) followed by SHV-1 like (35.5%) and CTX-14 like (11.3%); 32.3% of isolates contained more that one ESBL. No difference in activity was seen versus strains exhibiting multi-drug resistance or the production of specific ESBLs.
Conclusions: Using the BSAC breakpoint of 32 mg/L for urinary isolates we found 93.9% of the isolates to be sensitive. Moreover, temocillin achieves urinary levels of 400–600 mg/L suggesting a considerable margin over the MICs. Thus we conclude that temocillin is a useful option for the growing number of infections, particularly of the urinary tract, that are caused by ESBL and cephalosporin resistant organisms.

P1172 Evaluation of MicroScan Neg Combo Panel Type 44 for detecting extended spectrum β-lactamases in Enterobacteriaceae

M.N. Kim, H. Sung, A.J. Song, S.J. Lee (Seoul, Cheongju, KR)

Objectives: Accurate and rapid detection of extended spectrum β-lactamases (ESBLs) is important to guide proper patient antimicrobial therapy. The new MicroScan panel, Neg Combo Type 44 (Dade Behring, Sacramento, Calif., USA), has been developed for confirmation of ESBL-producing Enterobacteriaceae using the wells containing ceftazidime/clavulanic acid and cefotaxime/clavulanic acid. We evaluated the performance of Type 44 panel for confirmation of ESBLs.
Methods: In September 2007, 106 *Escherichia coli*, 81 *Klebsiella pneumoniae*, 11 *K. oxytoca*, and 8 *Proteus mirabilis* isolated from clinical specimens were tested with Type 44 panel. All isolates were tested with the disk approximation test (DAT) and CLSI phenotypic ESBL confirmation test (CLSI). The cefotetan-non-susceptible isolates were tested with cefotaxime and cefotaxime/clavulanate disk containing boronic acid for detection of plasmid-mediated AmpC β-lactamases (AmpC).
Result: Forty-four (21.4%) of 206 isolates were confirmed as ESBL-producers by DAT and/or CLSI including 27 *E. coli*, 14 *K. pneumoniae*, 2 *K. oxytoca*, and 1 *P. mirabilis*. Thirty-eight isolates flagged as "Confirmed ESBL" were all confirmed as ESBL-producers. Fourteen *K. pneumoniae* isolates flagged as "Possible ESBL, unable to interpret confirm test" were all confirmed as AmpC-producers. Of which, 6 (2.9%) were ESBL-producing as well as AmpC. All ESBL-producers were positively screened and ESBL-producers without AmpC were all confirmed by Type 44.
Conclusion: Type 44 warrants to be a reliable panel for detection of ESBLs in Enterobacteriaceae. The isolates that flagged as "Possible ESBL, unable to interpret confirm test" requires the confirmation for presence of AmpC.

P1173 Tigecycline activity against geographically diverse Enterobacteriaceae displaying multidrug-resistant phenotypes across Europe

C. Pillar, D. Draghi, C. Thornsberry, D. Sahm, M. Dowzicky (Herndon, Collegeville, US)

Objective: Infections derived from Enterobacteriaceae (EN) commonly occur among hospitalised patients and can be problematic to treat. Tigecycline, a new semi-synthetic derivative of minocycline and the first in the glycylcycline class of antibiotics, has previously shown activity against this family of organisms (Org). In 2006, tigecycline (TIG) was approved in Europe (EU) for treatment of complicated skin and skin structure infections and complicated intra-abdominal infections.
Methods: In total, 875 EN isolates were obtained from 28 hospitals in ten countries across EU during 2006 to 2007. Isolates were tested centrally by broth microdilution (CLSI M7-A7). TIG activity was analysed by MDR status defined as resistance to ⩾3 agents which included ampicillin, cefepime, ceftriaxone, ciprofloxacin, gentamicin, imipenem, minocycline, and piperacillin-tazobactam. EUCAST breakpoints were used to interpret TIG MIC results and CLSI (M100-S17) breakpoints were used to interpret all other agents, where applicable.
Results: See Table.

Org	category	Total N	TIG MIC (mg/L) Range	MIC_{90}	% Susceptible
EN	All	875	0.06–8	1	97.0
	Non-MDR	707	0.06–4	1	98.7
	MDR	168	0.06–8	2	89.9
E. coli	All	300	0.06–2	0.5	99.3
	Non-MDR	244	0.06–2	0.5	99.6
	MDR	56	0.06–2	0.5	98.2
K. pneumoniae	All	282	0.12–8	1	97.2
	Non-MDR	209	0.12–2	1	99.5
	MDR	73	0.12–8	1	90.4
Enterobacter spp.	All	124	0.25–2	1	91.1
	Non-MDR	96	0.25–2	1	96.9
	MDR	28	0.5–2	2	71.4
Citrobacter spp.	All	87	0.12–1	0.5	100
	Non-MDR	79	0.12–1	0.5	100
	MDR	8	0.12–1	NA	100
S. marcescens	All	82	0.25–4	1	93.9
	Non-MDR	79	0.25–4	1	94.9
	MDR	3	0.5–4	NA	66.7

Conclusions: Overall, EN was 97% susceptible to TIG. The TIG MIC90 against all EN tested did not exceed 2 mg/L, regardless of MDR phenotype. The potential for resistance to any new agent to increase with use and time dictates the need for continuous monitoring of TIG activity against this group of target pathogens.

P1174 In vitro activity of fosfomycin vs. extended-spectrum β-lactamase

A. Amin, P. Khanna, C. O'Sullivan, D. Wareham (London, UK)

Objectives: Due to the increased isolation of ciprofloxacin resistant ESBL-producing Enterobacteriaceae from the urinary tract, alternative antibiotics are urgently required. Among currently available agents, fosfomycin trometamol may be a useful agent as it concentrates in the kidney and bladder. We set out to determine the in-vitro activity of fosfomycin against both community and hospital acquired urinary tract infection (UTI) isolates from the east London Region of the UK.
Methods: All isolates collected were screened for ESBL production using double disk synergy tests with cefpodoxime and cefpodoxime/clavulanate. Strains were identified to species level using a combination of chromogenic media and API 20E identification systems. Susceptibility to gentamicin, ampicillin, amoxicillin/ clavulanate, cephalexin, cefuroxime, ciprofloxacin, piperacillin/tazobactam, amikacin, trimethoprim, aztreonam, ceftazidime, nitrofurantion, minocycline, ampicillin/sulbactam, cefoxitin, trimethorpim/sulfamethoxazole, fosfomycin and imipenem were determined using the BSAC disc diffusion method. Minimum inhibitory concentrations (MIC) of fosfomycin were determined by agar dilution using isosensitest agar. All ESBLs were characterised by multiplex PCR for genes encoding CTXM3-like, CTXM14-like and SHV-like β-lactamases.
Results: 75 urinary isolates were tested, all of which were resistant to amoxicillin and cephalexin. 81.3% were also resistant to trimethoprim, 34.7% to nitrofurantoin, and 85.3% to ciprofloxacin, 74 out of 75 isolates (98.7%) were sensitive to fosfomycin, using the BSAC MIC breakpoint of 128 mg/L. MICs to fosfomycin ranged from 0.5–>128 mg/L, with an MIC50 of 16 and an MIC90 of 32 mg/L. CTXM3-like genes were detected in 82.5% of isolates, CTXM14-like genes in 12.3%, and SHV-like genes in 36.8%.
Conclusions: 98.7% of ESBL-producing urinary isolates tested in this study were sensitive to fosfomycin, with frequent resistance to other agents including ciprofloxacin. Fosfomycin is an oral agent which is known to be concentrated in the urine. It is not nephrotoxic, is considered safe in pregnancy, and is also active against *Enterococcus* species. This study suggests that fosfomycin may be a useful option in the treatment of urinary tract infections caused by multi-resistant organisms.

P1175 Efficacy of a mixture of colloidal silver-hydrogen peroxide and 2-bromo-2-nitropropan, 1,3-diol compounds against different *Legionella pneumophila* strains

A. Kimiran-Erdem, N.O. Sanli-Yurudu, E.O. Arslan-Aydogdu, Z. Zeybek, S. Gurun, A. Cotuk (Istanbul, TR)

Objectives: *Legionella pneumophila*, the causative agent of Legionnaires' disease and Pontiac fever, can be isolated from a variety of potential human contact areas (cooling tower systems, potable water sources, etc.). Because of the potential for any water system to harbour, amplify and disseminate legionellae, control measures need to be considered for all water systems. Therefore, in order to prevent legionellosis outbreaks, contaminated water systems must be disinfected and the most effective and practical biocides need to be evaluated. The aim of this study is to determine the lethal activity of various concentrations of a mixture of colloidal silver-hydrogen peroxide (CSHP) and 2-bromo-2-nitropropan, 1,3-diol (BNPD) compounds on *L. pneumophila*. The susceptibility of environmental isolates [SG 1 and SG 2–14] and standard strain to biocides was assessed at different contact times.
Methods: In the current study, the qualitative suspension test method by Skaliy et al. was modified based The American Society for Testing Materials (ASTM) E 645–91 standard test method, which is used for determining the efficacy of microbicides used in cooling systems.
Results: CSHP compound was found effective at the recommended dosages (200–500 ppm) against legionellae, since these concentrations achieved >5 log reduction at 0 hour contact time. Furthermore, all strains were killed by lower doses (100 ppm and 50 ppm) in 3 hours contact time. Recommended BNPD concentration (100 ppm) for cooling towers killed SG 2–14 and standart strains at 3 hours contact time, however SG 1 strain was killed at 6 hours contact time. The antibacterial activity of lower doses BNPD (50 and 25 ppm) against SG 1 and standard strains required longer contact times than recommended dosages.
CSHP compound was found more effective than BNPD in terms of recommended dosages and contact times.
Conclusion: CSHP compound can be recommended for decontamination of legionellae. Since, several factors such as bacterial strains, biocides and conditions in the water sytems can affect efficiency of a biocide against bacteria, activity of the biocide needs to be evaluated in laboratory conditions before practical usage.

P1176 Resistance of *Campylobacter* spp. to fluoroquinolones and macrolides in Portugal

A. Vicente, T. Hanscheid (Caldas da Rainha, PT)

Objectives: When indicated, empirical treatment of diarrhoea in adults is often based on quinolones. However, the resistance of *Campylobacter* spp. to quinolones is increasing globally. Because no good data exist for Portugal, this study aimed to establish the resistance pattern in *Campylobacter* spp., isolated from human faeces.
Methods: The antimicrobial susceptibility of *Campylobacter* strains isolated from human diarrhoeal stool samples was studied. Strains isolated in Portuguese Hospital Laboratories, from 2003 onward were included. The activity of five antimicrobial drugs was tested: ciprofloxacin (CI), moxifloxacin (MX) and gatifloxacin (GA), as well as erithromycin (EM) and azitromycin (AZ). The MICs were determined with E-test strips. Since no specific breakpoints have yet been established for *Campylobacter* spp., we used the breakpoints from the Clinical Laboratory Standards Institute (CLSI) for Enterobacteriaceae (for CI and GA), for *Staphylococcus* spp. (for EM and AZ) and for *S. pneumoniae* (for MX). This allows the comparison with other studies, as these breakpoints are also used by other investigators.

Results: In this ongoing study, 123 *Campylobacter* strains were analysed so far. *Campylobacter jejuni* was the predominant species recovered: 110 isolates (89.5%), of which 66.7% were identified as *C. jejuni jejuni* 1. A total of 80.5% (99 of 123) of *Campylobacter* strains were found to be resistant to ciprofloxacin, followed by those strains resistant to moxifloxacin and gatifloxacin (51.2 and 47.2%, respectively). Interestingly, both MX and GA still showed antimicrobial activity in 29.3% and 33.3% of CI resistant cases, respectively. The MIC50s values for MX and GA were 4.0 and 6.0 μg/ml, respectively, while the value for ciprofloxacin was 32 μg/ml. A clearly different pattern was observed with respect to macrolides, to which only 6.5% of the strains studied were resistant.
Conclusion: Portugal seems to have one of the highest quinolone resistance rates in Europe, comparable with Spain (~80%). Consequently, quinolones can no longer be considered the empirical treatment of choice. If treatment is indicated, macrolides should be used, as most strains are still sensitive. However, the study raises further questions that need to be addressed: possible treatment options for the patients that show quinolone and macrolide resistance and the excessive use of quinolones in husbandry.

P1177 Comparative activity of various antimicrobial agents against *Bacteroides fragilis* group strains

C. Betriu, I. Rodríguez-Avial, F. López, E. Culebras, M. Gómez, J.J. Picazo (Madrid, ES)

Objectives: *Bacteroides fragilis* group organisms are the most frequently isolated anaerobic bacteria in clinical infections. Increasing resistance of this group of organisms to several agents and geographical differences in resistance patterns have been reported in recent years. The purpose of this study was to asses the antibiotic susceptibility patterns of *Bacteroides fragilis* group strains isolated in our hospital.
Methods: A total of 277 non-duplicate clinical strains of the *Bacteroides fragilis* group collected from January 2005 to December 2006 were included in the study. Organisms were identified by the Rapid ID 32 A system. Susceptibilities were determined by the agar dilution method according to the CLSI criteria. The following agents were studied: metronidazole, chloramphenicol, clindamycin, tigecycline, moxifloxacin, amoxicillin-clavulanate, piperacillin-tazobactam, cefoxitin, and imipenem.
Results: Cefoxitin inhibited 63.5% of the strains at 16 mg/L. Clindamycin was the least active of the compounds tested (44.7% resistance). All isolates were susceptible to metronidazole. One isolate showed intermediate resistance to chloramphenicol, being the rest of them susceptible to this antibiotic. Tigecycline inhibited at 4 mg/L 87% of the strains. The resistance rates for amoxicillin-clavulanate and piperacillin-tazobactam were 10.1 and 2.2%, respectively. We found two *B. fragilis* isolates that were highly resistant to imipenem (MIC > 256 mg/L) and to all other β-lactam agents tested. For moxifloxacin, MIC50 and MIC90 were 1 and 8 mg/L, respectively. Among the different species of the group, *B. fragilis* was the most susceptible to clindamycin and cefoxitin, while B. thetaiotaomicron was the least susceptible to these agents.
Conclusion: The high resistance rates to clindamycin and cefoxitin and the emergence of resistance to the new β-lactams observed in this study, indicate the need of continued surveillance of susceptibility of these organisms in order to detect changes in susceptibility profiles and to select the adequate antimicrobial therapy.

P1178 Resistance of *Bacteroides* species in Trondheim, Norway

R. Hannula, G. Iversen (Trondheim, NO)

Objectives: Bacteria belonging to the *Bacteroides fragilis* group are predominant in clinical anaerobic infections. Increasing resistance to several antibiotics has been reported in the last decades. From December 2005 until November 2007 all *Bacteroides* strains from clinical samples at our hospital were tested with Etest for five antibiotics.
Methods: The samples were cultured on fastidious anaerobic agar (FAA). Susceptibility testing was performed for Gram-negative bacteria, which were identified biochemically by rapid ID32A (BioMérieux) as *Bacteroides* species. A suspension of bacteria in Brain Heart broth of 1 McFarland turbidity was floated on PDM agar with 5% defibrinated horse blood. Etest strips (BIODISK) were applied on the dry agar surface. The MIC was read at full inhibition after 24 hours and for clindamycin after 48 hours of incubation. All culturing and susceptibility testing was performed in an anaerobic chamber and all media were prereduced.
Results: 125 isolates, cultured mainly from pus obtained by abdominal surgery and abscess drainage, were available for testing. One strain was excluded due to no growth on the Etest. The breakpoints recommended by the Norwegian Working Group on Antimicrobials (NWGA) were applied. Penicillin resistance was detected in all strains except one (*B. ureolyticus*). No strains were resistant to metronidazole, one strain (*B. capillosus*) had reduced metronidazole sensitivity. Only one strain (*B. fragilis*) was resistant to imipenem. Resistance to clindamycin and piperacillin/tazobactam was more common, 37.9% and 20.2% respectively. *B. fragilis* isolates were more sensitive to these two antibiotics than non-*fragilis* species.
Conclusion: Metronidazole and imipenem are good alternatives for empiric therapy of infections with *Bacteroides*. Species identification and susceptibility testing should be done in serious infections.

P1179 Comparison of the Etest and the Neo-Sensitabs method for antimicrobial susceptibility testing of *Helicobacter pylori*

L. Rasmussen, L. Jonaitis, L. Kupcinskas, L. Andersen (Copenhagen, DK; Kaunas, LT)

Objectives: To assess the reliability of the E-test (AB BIODISK) compared with the Neo-Sensitabs (Rosco) method for antimicrobial susceptibility testing of *Helicobacter pylori*.
Methods: *H. pylori* strains were susceptibility tested by both the E-test and the Neo-Sensitabs method for ampicilin, metronidazole, ciprofloxacin, tetracycline and clarithromycin.
50 clinically isolated *H. pylori* strains were grown on chocolate agar plates and incubated at 37ºC in a microaerobic gas chamber. The bacteria were harvested after 72 hours, suspended in API suspension medium (bioMérieux) and adjusted to a McFarland turbidity standard of 4 (109 CFU/ml). Inoculation was performed by applying 100 ml of the bacteria suspension to each plate (plates were room tempered before inoculation) and spread by drigalski loop. Before applying the E-test strips and the Neo-Sensitabs plates were left to dry for 15 minutes. The strips/tablets were applied using sterile forceps and only one strip/tablet per plate was applied. Incubation was conducted at 37ºC in a microaerobic gas chamber and reading after 72 hours.
In order to allow a direct comparison of E-test and tablet results, MIC (Minimal inhibitory concentration) values were first log2 transformed and then converted to scores ranging from 1 to 15 [1]. Correlations between scored MIC and zonesize were tested using Pearson's regression.

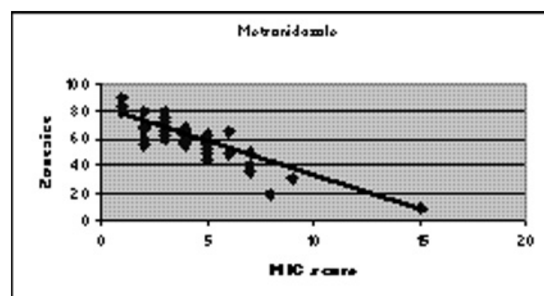


Figure 1. Correlation between metronidazole MIC values and zonesizes with 50 *H. pylori* isolates.

Results: Zonesize is plotted as a function of scored MIC of ampicilin, metronidazole, ciprofloxacin, tetracycline and clarithromycin

and correlations calculated. The corresponding correlation coefficients are –0.49, –0.97, –0.89. –0.49 and –0.67 respectively. As an example Figure 1 shows the results of metronidazole.

Conclusion: Excellent correlation was demonstrated by statistical analysis between MIC score and zonesize values for metronidazole and ciprofloxacin while the correlation was acceptable for ampicilin, tetracycline and clarithromycin.

P1180 Clarithromycin resistance in *Helicobacter pylori* positive patients after therapies failure

L. Franzin, D. Cabodi, N. Bonfrate (Turin, IT)

Objectives: Patients with peptic ulcers who are also infected by *Helicobacter pylori* receive antimicrobial therapy, based on different antibiotic combination including clarithromycin in addition to antisecretory drugs. Eradication is however difficult because of primary and secondary resistance. The aim of the study is to evaluate in vitro susceptibility of *H. pylori* strains isolated in a group of symptomatic patients with failure of previous eradication treatments.

Methods: 77 adult patients (27 males and 50 females) with peptic ulcers and other gastric disorders after failure of previous treatment regimens were studied. The mean age of the subjects was 54.7 years and the range 31–77 years. During endoscopy, four biopsies were taken from antrum for histology, rapid urease test and culture and two from fundus for histology and culture. A total of 144 gastric biopsies were collected. The specimens were homogenised and streaked on fresh blood agar plates and on Dent agar. The plates were incubated in a microaerophilic atmosphere at 37°C for 4 up to 10–14 days. Fresh culture of 3 days were tested for susceptibility to clarithromycin, amoxicillin, metronidazole and tetracycline by agar disk diffusion technique and by E-test method. The plates were incubated in a microaerophilic atmosphere at 37°C for 3 days.

Results: *H. pylori* was isolated from 46 (59.7%) patients; in the other subjects the culture showed no growth or contamination. Best results of isolation were obtained in blood agar plates, but Dent agar was superior when bacterial contamination was present. Clarithromycin resistance was found in 80% of the patients, metronidazole in 75% and amoxicillin in 2.5%. All strains were susceptible to tetracycline. Results obtained by agar disk diffusion technique and by E-test were concordant. Resistance to at least one drug was observed in 95% of subjects. Resistance to both clarithromycin and metronidazole was found in 57.5% of the cases. All patients with clarithromycin resistance were previously treated with clarithromycin and amoxicillin.

Conclusion: The percentage of clarithromycin resistant strains from patients with previous therapies failure is very high (80%); this percentage grow up to 100% in subjects previously treated with this drug. Resistance to tetracycline was never observed here. As this antibiotic should be used in combined alternative treatment, it should be considered in susceptibility testing.

P1181 Comparison of two disc diffusion methods with minimum inhibitory concentration for antimicrobial susceptibility testing of *Neisseria gonorrhoeae* isolates

P. Khaki, P. Bhalla, P. Sharma, S. Moradi Bidhendi (Karaj, IR; New Delhi, IN)

Background: Gonorrhoea remains a public health problem in developing countries. Antimicrobial susceptibility testing of *N. gonorrhoeae* helps in monitoring the trends and efficacy of treatment guidelines for syndromic management of gonorrhoea. Antimicrobial susceptibility testing of *N. gonorrhoeae* isolates is widely performed as per the CLSI guidelines or by the AGSP method. Results of antimicrobial susceptibility testing by disc diffusion method should be reliable when compared to MIC values.

Objective: The present study was carried out to compare two disc diffusion methods (CLSI and AGSP) with MIC determination for antimicrobial susceptibility testing of gonococcal isolates.

Methods: A total of 100 *N. gonorrhoeae* isolates were studied. The strains were isolated from 89 (86.4%) out of 103 men with urethritis, 5 (12.8%) out of 39 women with endocervicitis and 6 (46.1%) out of 13 sexual contacts who attended the STD clinic of Lok Nayak Hospital, New Delhi between January 2004 and June 2006. All isolates were examined for susceptibility to penicillin, ciprofloxacin, tetracycline, ceftriaxone and spectinomycin by the disc diffusion methods (CLSI and AGSP). MIC was determined by E-test method. β-lactamase production was assayed by chromogenic cephalosporin method. Quality control strains were included for both disc diffusion and MIC methods.

Results: All isolates were susceptible to ceftriaxone and spectinomycin while 99 (99%) were resistant to ciprofloxacin by both disc diffusion methods. Thirty-two (32%) strains were found to be resistant to penicillin by CLSI method, while 40(40%) were resistant to penicillin by AGSP method. Seventeen (17%) isolates were PPNG and 20 (20%) were TRNG. All PPNG strains had no zone of inhibition by AGSP, while they had an inhibition zone ± 19 by CLSI. There was complete agreement between results of antimicrobial susceptibility testing by both disc diffusion methods and MIC values for all antibiotics except penicillin for which the kappa was 0.7 for AGSP and 1 for CLSI.

Conclusion: The continual spread and ongoing emergence of resistance among *N. gonorrhoeae* isolates require that an accurate and simple test be performed to determine antimicrobial susceptibilities. Both disc diffusion methods showed a high degree of agreement with MIC values. Although AGSP method is more economical, its feasibility depends on the availability antimicrobial discs of low potency and it requires more accuracy in measuring the inhibition zones.

P1182 Antimicrobial susceptibility of Gram-negative bacteria causing nosocomial infections from 2003–2005 in a university hospital in Turkey

F. Kibar, B. Kurtaran, A. Candevir, A.S. Inal, A. Bicer, E. Oksun, Y. Tasova, A. Yaman (Adana, TR)

Objective: The aim of this study was to determine about antibiotic susceptibilities of Gram-negative bacteria isolated from nosocomial infections.

Methods: The activity of eight broad-spectrum antimicrobial agents were assessed against 397 Gram-negative aerobic bacteria isolates collected from nosocomial infections during 2003, 2004 and 2005 in an university hospital in Turkey. Gram-negative bacteria were including *E. coli*(22.6%), *K. pneumoniae* (21.9%), *P. aeruginosa* (20.9%), *Acinetobacter* spp. (20.1%), *Enterobacter* spp. (7.3%), *Proteus* spp. (3.2%), *Morganella* spp. (1.2%), *Providencia* spp. (1.0%), *Serratia* spp. (0.7%) and *Citrobacter* spp. (0.5%). Antimicrobial susceptibility was investigated using E-test. Extended-spectrum β-lactamase (ESBL) production was determined using ceftazidime and ceftazidime/clavulanic acid E-test strips.

Results: Overall, meropenem and imipenem were the most effective antibiotics against Gram-negative organisms, respectively (77.5% susceptible, MIC50 = 0.125, MIC90 ⩾ 32 mg/L; 75.8% susceptible, MIC50 = 0.5, MIC90 ⩾ 32 mg/L); these were followed by piperacillin/tazobactam (56.4% susceptible; MIC50 = 16, MIC90 ⩾ 256 mg/L), ciprofloxacin (44.8% susceptible; MIC50 = 3, MIC90 ⩾ 32 mg/L), cefepime (42.8% susceptible; MIC50 = 24, MIC90 ⩾ 256 mg/L), tobramycin (39.2% susceptible; MIC50 = 16, MIC90 ⩾ 256 mg/L), ceftazidime (38.5% susceptible; MIC50 = 24, MIC90 ⩾ 256 mg/L) and cefotaxime (25.4% susceptible; MIC50 ⩾ 32, MIC90 ⩾ 32 mg/L). When these were compared with data between 2000–2002, the antibiotic susceptibilities were determined approximately lower 10% for imipenem, meropenem, piperacillin/tazobactam; 15% for cephotaxime; 20% for ceftazidime, cefepime, ciprofloxacin and tobramycin in 2003–2005. The rates of production of ESBL were 77% in *K. pneumoniae* and 61% in *E. coli*. These ESBL

positive isolates were sensitive 100%, 98% to meropenem; 98.5% and 98% to imipenem, respectively. Multi-drug resistance (MDR) rates were 76% in *Acinetobacter* spp., 66% in *P. aeruginosa*. Only piperacillin/tazobactam were more susceptible than 50% against *P. aeruginosa*. Carbapenems were the most active agents against *Acinetobacter* spp. (meropenem 57.5%, imipenem 55% susceptible) AmpC β-lactamase was produced by 31.4% of *Enterobacter* spp., *Citrobacter* spp. and *S. marcescens*. All of these were sensitive to meropenem; 77%, to imipenem and ciprofloxacin.
Conclusion: Antimicrobial resistance has reached very high levels in hospital. Solving of this problem depends primarily on to prevention of the development of antimicrobial resistance.

P1183 In vitro activity of tigecycline against multidrug-resistant Gram-negative clinical isolates

O. Zarkotou, K. Kopsari, E. Korou, J. Tsimettas, P. Mantzouratou, D. Gianneli, C. Poulopoulou (Athens, GR)

Objectives: To evaluate the antimicrobial performance of tigecycline against multi-drug resistant (MDR) Gram-negative (GNs) clinical isolates.
Methods: A total of 78 MDR GN bacterial stains were studied. They were isolated from various clinical specimens, during a 10-month period (2/07–11/07), from both ICU and non-ICU patients. Only one isolate per patient was included in the study. *P. aeruginosa* and Proteae strains were excluded, as tigecycline exhibits reduced antimicrobial potency to these species. Species identification and MIC values determination for 37 antibiotics were performed by the VITEK 2 Compact Automated System (bioMerieux, France). The MICs for tigecycline and ampicillin/sulbactam were determined by the E-test method (AB Biodisk, Sweden). The susceptibility breakpoints for tigecycline were those approved by the FDA.
Results: The majority of the MDR strains derived from ICU-patients (51/78, 65.4%) as expected, followed by surgical patients (19/78, 24.4%). They were isolated from blood (35/78), pus (19/78), catheters (11/78), bronchial secretions (7/78) and other sources (6/78). The bacterial species were: *K. pneumoniae* (31/78), *A. baumannii* (27/78), *Enterobacter* spp. (10/78), *E. coli* (5/78) and others (5/78). Out of the 78 MDR strains five were pan-drug resistant and ten of them were susceptible only to colistin. Susceptibility to tigecycline was detected to 4/5 of pan drug resistant isolates (one was intermediately susceptible) and to 6/10 of colistin-only susceptible isolates (two of them were tigecycline resistant). MIC90 and MIC50 for tigecycline was 2 and 0.75 mg/l respectively (MIC range: 0.064–8 mg/l). *Acinetobacter baumannii* exhibited higher MIC90 and MIC50 values (3 and 2 mg/l, range: 0.125–8 mg/l) compared with *Klebsiella pneumoniae* (1, 5 and 0, 38 mg/l, range: 0.094–8). Resistance to tigecycline was detected to 2 MDR isolates (2, 6%) with MICs of 8 mg/l, while in 5 strains (6.4%) MICs were 3–4 mg/l. Among ICU-patients 8 were treated with tigecycline. No significant differences were observed to the MIC values of tigecycline for the strains derived from these patients before and after treatment.
Conclusion: The emergence of multidrug-resistance poses a serious threat. Tigecycline may represent an option for the treatment of infections caused by MDR GNs where our choices are limited. Any potential for selection of resistance should be monitored.

P1184 Current susceptibility patterns for *H. influenzae* and M. catarrahlis isolates from Europe: findings of the 2007 GLOBAL surveillance program

N. Brown, C. Thornsberry, D. Draghi, M. Aranza, C. Pillar, D. Sahm (Herndon, US)

Objective: *Haemophilus influenzae* (HI) and *Moraxella catarrhalis* (MC) associated with community-acquired respiratory tract infections can become resistant to commonly prescribed agents and these resistance (R) rates can vary according to regional distributions. The GLOBAL Surveillance (SUR) initiative was undertaken to track R patterns among respiratory pathogens. This study tracks the resistance of HI and MC collected as part of GLOBAL '07 to empirically used oral agents.
Methods: During 2007, 858 HI and 163 MC isolates from patient specimens were collected from 6 European (EU) countries: Belgium, France, Germany, Italy, Spain (SPN), and the United Kingdom. All isolates were centrally tested by broth microdilution according to CLSI M7-A7 and the results were interpreted according to CLSI M100-S17. Data were analysed according to β-lactamase (BL) status as positive (+) or negative (−).
Results: For all EU countries combined, 130 HI isolates were BL+ (15.2%) and 728 isolates were BL− (84.8%). Overall, current MIC90s (mg/L) were >8 for ampicillin (AMP), 0.03 for levofloxacin (LFX), and >4 for trimethoprim-sulfamethoxazole (SXT), regardless of BL phenotype, except for BL− isolates against AMP (MIC90, 0.5 mg/L). The current overall percent R among the oral agents were 15.4% AMP, 0.1% LFX, and 18.3% SXT. By country, LFX retained potent activity against HI, regardless of phenotype, based on MIC90s (0.015–0.03 mg/L for all) and susceptibility (%S) was 100% for all, except SPN (overall %S=99.4), where 1 isolate was non-susceptible. One HI isolate was found to be BL− ampicillin-resistant. For all EU countries combined, 160 MC isolates were BL+ (98.2%), with <2% BL−. With the exception of ampicillin and cefuroxime, all agents were highly active against the tested MC, with 100% susceptibility rates.
Conclusion: Among HI, R to SXT and AMP (BL mediated) was prevalent throughout EU. In contrast, current %S to LFX remains high throughout EU against HI. Against MC, isolates are 100% susceptible to all agents, with the exception of ampicillin and cefuroxime, regardless of BL+ rates among MC which have reached 98%. Continued SUR is warranted to monitor any changes that may occur among these respiratory pathogens to help guide empiric therapy for community-acquired respiratory tract infections.

P1185 Comparison between AST-N058 card (VITEK 2) and UNMIC/ID-62 panels (BD Phoenix) ESBL test for detection of extended-spectrum β-lactamases in *E. coli* and *K. pneumoniae*

M. Treviño, L. Martinez-Lamas, P.A. Romero-Jung, L. Moldes, C. Garcia-Riestra, B.J. Regueiro (Santiago de Compostela, ES)

Objective: The aim of this study was to evaluate the abilities of the VITEK 2 and BD Phoenix in detecting ESBL production.
Methods: One hundred and ninety eight clinical isolates of ESBL producers (178 *E. coli* and 20 *K. pneumoniae*) were assayed by VITEK 2 (BioMérieux, France) and BD Phoenix System (Becton-Dickinson Biosciences, Sparks, Md) using AST-N058 cards and UNMIC/ID-62 panels, respectively. Double-disk synergy test combined with Etest ESBL (ABBiodisk, Solna, Sweeden) were used as phenotypical reference method. Moreover, twelve strains with genotipically identified β-lactamases were used as controls.
Results: With Etest as the reference for the clinical isolates and the genoptype as the reference for the control strains, the ESBL specific test of the AST-N058 card and UNMIC/ID-62 panels detected the ESBLs with accuracies of 99.49% and 89.39%, respectively. No significant difference between the systems with regard to the control strains was detected. Because of BDXpert system, the Phoenix enhanced its accuracy up to 96.46%. However, the VITEK 2 expert system considered as incoherent the AST results in 7 isolates with ESBL positive tests.
Conclusions: The ESBL test of the VITEK 2 system (AST-N058 card) performed better than Phoenix (UNMIC-ID 62 panel) in detecting the ESBLs produced by clinical isolates of *E. coli* and *K. pneumoniae*. Nevertheless, the action of expert systems put on the same level both automated systems.

P1186 Comparative mutant prevention concentration values for tigecycline and ciprofloxacin against clinical isolates of *Escherichia coli*

J. Blondeau, S. Borsos (Saskatoon, CA)

Objectives: The mutant prevention concentration (MPC) defines the antimicrobial drug concentration that blocks the growth of the least susceptible cell from high density bacterial inocula. Tigecycline, a member of a new class of antimicrobials (glycylcylines) has been shown to have in vitro activity against clinical isolates of *E. coli*. We tested *E. coli* isolates by MPC against tigecycline and ciprofloxacin to determine if strains with high ciprofloxacin MPCs would impact on values for tigecycline.
Methods: A total of 24 strains collected from patients with urinary tract infection were studied. For MPC testing, 10^{10} CFUs were applied to Mueller-Hinton agar plates containing doubling drug concentrations of each drug. Following incubation under optimal conditions for 24–48 hours, the lowest concentration preventing growth was recorded as the MPC.
Results: For all strains tested, tigecycline MPC values ranged from 0.5–2 mg/L; 18 strains (75%) having MPCs at 0.5 mg/L and 5 (21%) at 1 mg/L. For ciprofloxacin, MPC values ranged from 0.031 to ⩾32 mg/L; 7 strains (29%) had MPC values of ⩾2 mg/L with 3 strains (12.5%) at ⩾32 mg/L. Tigecycline MPC against the 7 strains with elevated ciprofloxacin MPC values were 0.5–1 mg/L.
Conclusions: Tigecycline MPC values were low against clinical isolates of *E. coli* with 96% of strains having values of 0.05–1 mg/L. As well, high MPC values to ciprofloxacin did not negatively impact on tigecycline. Tigecycline may be a suitable alternative for therapy in patients infected with quinolone resistant *E. coli*.

P1187 The activity of mecillinam against *Escherichia coli* with defined mechanisms of resistance to 3rd generation cephalosporins

M. Wootton, T.R. Walsh, R.A. Howe (Cardiff, UK)

Objectives: Resistance to 3rd generation cephalosporins (3GC) in *E. coli* is an increasing problem across the world with resistance rates in some parts of Europe (including the UK) of more than 15% in bacteraemia isolates. The main cause has been the spread of CTX-M Extended Spectrum Beta-Lactamases (ESBLs) but other enzymes such as plasmid-borne AmpC-type and OXA β-lactamases are being increasingly recognised and in some parts of the world *E. coli* strains with multiple enzymes are becoming more common. Mecillinam is an amidinopenicillin that is available in Europe as the oral pro-drug pivmecillinam, and is stable to many β-lactamases. We aimed to establish the activity of mecillinam against an international collection of *E. coli* with defined, often multiple, mechanisms of resistance to 3GC.
Methods: The isolates studied were 30 *E. coli* from an international collection with known β-lactamase content. Presence of specific β-lactamases has previously been established by PCR and sequencing. The collection includes isolates with TEM, SHV, CTX-M, CMY, AmpC, and OXA enzymes, and isolates with multiple enzymes. Susceptibility testing was performed by the BSAC agar dilution method on IsoSensitest agar with an inoculum of 10^4 cfu/spot.
Results: The susceptibility results are shown in the table. All isolates remained sensitive to mecillinam (breakpoint ⩽8 mg/L) and meropenem irrespective of the presence of β-lactamases. For three isolates that contained 5 or more β-lactamases, isolate 4 (TEM, CTX-M1, CMY-2, OXA-1, OXA-2), isolate 7 (TEM, SHV, CTX-M, CMY, OXA-1, OXA-2), and isolate 8 (TEM, SHV, CTX-M1, CTXM2, OXA-2) the mecillinam MICs were 1, 4, and, 8 mg/L respectively.
Conclusions: With the spread resistance to 3rd generation cephalosporins, it is important to find alternative agents. Unfortunately many strains exhibit multi-resistance to unrelated compounds as seen in this study. However mecillinam retains activity against *E. coli* even in the presence of multiple β-lactamases. It should be further evaluated to establish its clinical utility in the treatment of infections caused by such organisms.

	MIC_{50}	MIC_{90}	% Sensitive
Mecillinam	0.5	4	100
Meropenem	0.03	0.06	100
Cefotaxime	32	>128	18.8
Amoxicillin	>128	>128	0
Co-amoxiclav	>128	>128	0
Piperacillin/tazobactam	16	128	56.3
Ciprofloxacin	8	128	43.8
Nitrofurantoin	16	64	18.8
Trimethoprim	>128	>128	31.3
Gentamicin	0.5	64	56.3

P1188 The in vitro susceptibility of *E. coli* and *P. aeruginosa* from Minsk, Belarus

K. Bowker, V. Gorbunov, L. Titov, A. MacGowan (Bristol, UK; Minsk, BY)

Objectives: In this study we assessed the antimicrobial susceptibility of 69 *E. coli* (2 ESBL+ve) and 61 *P. aeruginosa* strains from Minsk, Belarus.
Materials and Methods: The following antimicrobials were utilised; meropenem (MER), amoxicillin (AMOX), co-amoxiclav (Co-A), cefotaxime (CTX), ceftazidime (CAZ), (tigecycline (TGC), sulphamethoxazole/trimethoprim (COT), piperacillin/tazobactam (P/T), gentamicin (GEN), amikacin (AMI) and ciprofloxacin (CIP). MICs were performed using CLSI agar dilution methodology using cation-adjusted Mueller Hinton agar. The percentage resistant using CLSI breakpoints were calculated.
Results: The range, MIC50 and MIC90 (mg/L) are shown on the table below. Using CLSI breakpoints and MIC90 data all *E. coli* strains were susceptible with the exception of AMOX and Co-A. CIP was the most potent agent tested (0.015 mg/L). Levels of resistance in *P. aeruginosa* were much higher with 15–35% of strains being resistant to MER, CAZ, P/T, AMI and CIP. 77% resistance to GEN was observed.

Antibiotic	*E. coli* n = 69				*P. aeruginosa* n = 61			
	range	MIC_{50}	MIC_{90}	% R	range	MIC_{50}	MIC_{90}	% R
Meropenem	⩽0.008–0.12	0.015	0.03	0	0.06–16	4	16	17
Amoxicillin	2–>128	>128	>128	57	NT	NT	NT	NT
Co-amoxiclav	4–>128	32	>128	57	NT	NT	NT	NT
Cefotaxime	0.03–128	0.03	0.12	3	16–>128	32	>128	67
Ceftazidime	0.06–64	0.12	0.5	3	1–>128	4	>128	27
Tigecycline	0.25–0.5	0.25	0.5	0	NT	NT	NT	NT
Sulph/trim	0.12–128	0.03	0.5	0	NT	NT	NT	NT
Pip/taz	1–32	2	16	0	2–>128	16	>128	32
Gentamicin	0.25–>128	1	2	8	1–>128	32	>128	77
Amikacin	0.05–>128	2	4	2	2–>128	16	>128	25
Ciprofloxacin	<0.008–128	0.015	1	9	0.12–>128	32	64	28

NT = not tested.

Conclusion: Rates of resistance in *E. coli* were low with significant resistance occurring only to amoxicillin with and without clavulanate. Two strains were ESBL positive. In contrast resistance in *P. aeruginosa* was high, only 20% were susceptible to gentamicin.

P1189 **Activity of ertapenem and other agents against clinical isolates of Proteeae producing extended-spectrum or AmpC-type β-lactamases**

E. Mantengoli, G.M. Rossolini (Siena, IT)

Background: *Proteus* spp. and other enterics of the tribe Proteeae (*Morganella morganii* and *Providencia* spp.) are common causes of urinary tract infections and sometimes responsible of other infections (e. g. wound, intra-abdominal and bloodstream infections). Strains with reduced susceptibility to expanded-spectrum cephalosporins due to production of extended-spectrum β-lactamases (ESBLs) or AmpC-type enzymes have emerged in several settings and, in Italy, have a notable epidemiological impact. In this work we investigated the activity of carbapenems and other potentially active agents against a collection of clinical isolates of Proteeae producing a variety of ESBLs or AmpC-type β-lactamases.
Methods: Antibiotic susceptibility was determined by the CLSI agar dilution method or by Etest. Inoculum size effect was determined with 106 vs. 104 CFU/spot). Characterisation of ESBLs or AmpC-type enzymes was carried out by PCR and sequencing. A total of 102 nonreplicated clinical isolates of Proteeae (75 *Proteus mirabilis*, one *Proteus vulgaris*, five *M. morganii*, 15 *Providencia stuartii* and two *Providencia rettgeri*) producing an ESBL (TEM-, CTX-M- or PER-type) or an AmpC enzyme (CMY-2-like) were investigated.
Results: Using a standard inoculum (104 CFU), susceptibility rates were: ertapenem, 100%; piperacillin/tazobactam, 100%; imipenem, 96%; amoxicillin/clavulanate, 33%; ciprofloxacin, 18%; amikacin, 95%; tobramycin, 50%; and gentamicin 23%. Inoculum size variably affected carbapenem susceptibility. Overall, with higher inocula, susceptibility rates decreased to 98% or 42% for ertapenem and imipenem, respectively. Inoculum size effect was overall higher with strains producing TEM-type ESBLs or CMY-2-like AmpC enzymes.
Conclusions: Present results indicate that carbapenems and piperacillin-tazobactam were the most active agents against ESBL- and AmpC-producing Proteeae of clinical origin. Among carbapenems, ertapenem was the most active, and MICs remained usually lower than the breakpoint for susceptibility even in the presence of higher inoculum; imipenem susceptibility was remarkably affected by the inoculum size.
Acknowledgements: Work supported by a medical education grant from Merck.

Antibiotic resistance in Gram-positive organisms

P1190 **Characterisation of Gram-positive conjugative transposons in enterococci from different sources by a multiplex-PCR assay**

C. Novais, A.R. Freitas, L. Moreira, M.V. Francia, F. Baquero, L.V. Peixe, T.M. Coque (Porto, PT; Santander, Madrid, ES)

Objectives: Conjugative transposons (CTn) have contributed to the spread of tetracycline (TeR) and erythromycin (ErR) resistance and might influence the adaptation of enterococci to different environments. Diversity of CTn among enterococcal isolates was analysed by a new multiplex PCR assay that includes amplification of specific sequences of known CTn from Gram-positives and others Tn often associated with them.
Methods: We studied 146 *E. faecium* (Efm), 140 *E. faecalis* (Ef), 84 *Enterococcus* spp. from 114 patients of 3 hospitals (H, n = 314 isolates), 20 samples of 3 piggeries (PE, n = 33), 76 poultry retail samples from 2 butcher shops (P, n =167); 7 hospital sewage/river samples (SR, n = 33); and 2 healthy humans (HV, n = 3) from 1996 to 2006. Antibiotic susceptibility and conjugation experiments were performed by standard procedures. Species identification and characterisation of tet (tetM, tetO, tetL, tetS, tetK)/ermB genes was performed by PCR. A battery of multiplex PCR were developed for screening integrases, excisionases or tranposases of Tn916, Tn917; Tn5397, Tn5398, Tn5252, EfcTn1, or Tn5386. Specificity of the method was proved by using specific control strains and sequencing PCR products.
Results: Most isolates were non susceptible to tetracycline (Te, 81%). tet genes were identified among TeR (n = 391/325, 90%) and TeS (n = 34/235, 10%) isolates. Among isolates containing tet we found tetM, tetS and tetL in both *E. faecalis* (100%, 59%, 4%) and *E. faecium* (92%, 80%, 2%). Occurrence of int/xisTn916 or tnpA/tnpRTn917 was slightly higher for *E. faecalis* than for *E. faecium* or *Enterococcus* spp. (49%/ 32%/ 37% or 37% /25%/ 11%, respectively) and spread among H, P and PE isolates. Conversely, tndXTn5397 was more common among *E. faecium* than *E. faecalis* or *Enterococcus* spp. (47%, 6%, 27%, respectively) and mainly confined to P isolates. EfcTn1 was recovered from 2 swine isolates (*E. faecium* and *Enterococcus* spp.). Most of the isolates contained sequences of 2 Tn, mostly Tn916/Tn917. Tn sequences (Tn916, Tn917, Tn5397, Tn5398) were transferred in 58% of the cases.
Conclusion: This method enables to screen CTn and other Tn often associated with them in a high number of strains. Association of particular elements with some species probably reflects differences among bacterial communities exchanges to which they belong. We firstly described EfcTn1 among enterococcal from swine.

P1191 **Molecular epidemiology of vancomycin-resistant enterococci in Belgium, 2003–2006**

S. Malhotra-kumar, C. Emeleer, C. Lammens, S. Chapelle, H. Goossens (Antwerp, BE)

Background: To study the molecular epidemiology of vancomycin-resistant enterococci (VRE) isolated from clinical specimens from hospitalised patients in Belgium during 2003–06.
Methods: VRE were identified on a multipex PCR detecting vanA, B, C1/C2, D, E and G, and on vancomycin MICs. Speciation was done on a duplex PCR detecting ddl genes, and for non-*E. faecalis*/*faecium*, on a sodA PCR and DNA sequencing. MICs to ampicillin, ciprofloxacin, gentamicin, streptomycin, quinupristin/dalfopristin, and linezolid were determined by agar dilution. Presence of the linezolid resistance mutation G2576U was studied by PCR of the 23S rRNA and a subsequent RFLP using NheI. Presence of virulence genes asa1, gelE, cylA, esp, and hyl was detected by a multiplex PCR. Genetic relatedness was examined by PFGE using SmaI, and an MLST analysis on the predominant VRE clones.
Results: Ninety-three VRE were isolated during 2003–06. Of these, 77 (83%) were *E. faecium*, 12 (13%) *E. faecalis*, and 4 (4%) *E. gallinarum*. vanA, the predominant vancomycin resistance gene, was identified in 77 VRE, vanB in 5, vanA+vanB in 1, and vanC1/C2 in 4 isolates, while 6 VRE did not show presence of any van gene. The predominant PFGE clone 54, which constituted 52% of the VRE studied, was an ampicillin- and ciprofloxacin-resistant, vanA-harbouring, hyl-esp-positive *E. faecium*. MLST analysis showed clone 54 to belong to ST17/CC17. The esp gene was present in 84% of the total VRE and in 90% of the *E. faecium* isolates either alone or with hyl, gelE, asa1, cylA. Ampicillin resistance was observed in 86% isolates, high-level gentamicin resistance (MIC > 500 μg/ml) in 38%, high-level streptomycin resistance (MIC > 2000 μg/ml) in 91%, and combined high-level gentamicin and streptomycin resistance in 38% isolates. Among non-*E. faecalis* VRE, resistance to quinupristin/dalfopristin (MIC $\geqslant$4 μg/ml) was 14%. One *E. faecalis* was linezolid-resistant (MIC 16 μg/ml) and RFLP generated two bands confirming presence of the G2576U mutation in 23S rRNA. Three *E. faecium*, of which two belonged to clone 54, were intermediately resistant to linezolid (MIC 4 μg/ml), however, the G2576U mutation was not detected.
Conclusions: Our study highlights the predominance of an ampicillin- and ciprofloxacin-resistant vanA-harbouring, hyl-esp-positive *E. faecium* ST17/CC17 clone among hospital-associated VRE infections in Belgium. The esp virulence gene, a marker for hospital-adapted VRE with an epidemic potential, was identified in majority of the VRE studied here.

P1192 **Molecular epidemiology and antibiotic-resistant genes of *Enterococcus faecalis* causing paediatric infection in Cuba**

D. Quiñones-Pérez, D. Marrero, A. Llop, N. Kobayashi, R. del Campo (La Havana, Holguín, CU; Sapporo, JP; Madrid, ES)

Objetives: The aim of this work was investigate the genetic relatedness and antibiotic resistant determinants in *Enterococcus faecalis* isolates from clinical samples in a paediatric hospital from Cuba.
Methods: A total of 55 *E. faecalis* isolates were recovered from different clinical samples between January 2001/December 2004 from unrelated children admitted in a paediatric hospital in Cuba. Antimicrobial susceptibility was assed by the agar dilution method. Pulsed-field gel electrophoresis (PFGE)-SmaI was performed for assessing the clonal relatedness among the isolates. Presence of the antibiotic resistance genes: erm(B), erm(A), erm(C), mef(A), tet(M), aac(6′)-aph(2"), aph(3’), ant(6), ant(3")(9), aph(2")-id and aph(2")-ic were tested by PCR with specific primers.
Results: A total of 17 different patterns of PFGE were identified among the 55 *E. faecalis* isolates, detecting the same enterococcal clone in different patients. Presence of a single clon for a single patient was only detected in six cases. Particular multi-resistant *E. faecalis* clones were detected in different wards from the paediatric hospital suggesting an intrahospital circulation of the selected clones. aac(6′)-aph(2″) and aph(3′) genes was detected in all HLR-gentamicin and HLR-amikacin isolates, respectively; whereas the ant(6) gene were detected in the 75% of HLR-streptomycin isolates. Most of the isolates contained simultaneously genes for multiple aminoglycoside-modifying enzymes. The erm(B) gene was found in 72% of the erythromycin-resistant strains. Multi-resistance to three or more antibiotic families was observed in 27 isolates which belonged to 13 *E. faecalis* clones.
Conclusion: The circulation of particular clones exhibiting antibiotic resistance within the paediatric hospital and the dissemination of genes among these strains indicated the need of infection control measures and the monitoring of antibiotic susceptibility to prevent the selection or dispersion of resistant strains in the hospital.

P1193 **Phenotypic and genotypic characterisation of antimicrobial resistance in faecal enterococci of healthy humans and animals**

C. Torres, M. López, E. Ruiz, Y. Sáenz, E. Domínguez, E. Guerra, C. Tenorio, C. Lozano, F. Ruiz-Larrea, M. Zarazaga (Logroño, ES)

Objective: To characterise the phenotypes and genes implicated in antimicrobial resistance in faecal enterococci of healthy humans and animals.
Methods: 171 faecal samples of healthy animals (66 pigs, 22 pets and 15 bulls) and humans (50 children under two years old and 18 adults) were seeded onto mEnterococcus agar plates. Two colonies per sample were selected and identified. Susceptibility testing to 10 antimicrobials were carried out by agar dilution method and aminoglycoside, glycopeptide, macrolide and tetracycline resistance genes were studied by PCR and sequencing.
Results: A total of 133 *E. faecalis*, 63 *E. faecium*, 55 *E. hirae*, 4 *E. casseliflavus*, 4 *E. gallinarum*, 4 *E. avium*, 3 *E. durans* and 7 *Enterococcus* spp. were recovered. *E. faecalis* was found in 72% of the isolates from human origin, and this species in addition to *E. hirae* were the most prevalent ones among pig samples (43 and 37%, respectively). *E. faecium* was found in 57% of isolates from pets and bulls. The percentages of antibiotic resistance (found in isolates from pigs/pets and bulls/human samples) were as follows: tetracycline (93/66/54%), erythromycin (81/23/29%), ciprofloxacin (18/23/14%), penicillin (5/6/0%), vancomycin MIC > 8 mg/L (0.9/2/4%) and high-level resistance (HLR) to streptomycin (44/9/12%), gentamicin (6/6/5%) and kanamycin (37/9/14%). None of the 273 enterococci showed ampicillin- or teicoplanin-resistance, whereas the highest resistance were found to tetracycline (72%) and erythromycin (49%). One *E. faecalis* isolate of porcine origin showed a VanB phenotype characterised by acquired inducible resistance to vancomycin and susceptibility to teicoplanin (MICs of 8 mg/L and ⩽0.5 mg/L, respectively). The vanC gene was found in the six *E. gallinarum* and *E. casseliflavus* isolates recovered from human and bulls. The ant(6)-Ia, aac(6′)-aph(2″) and aph(3′)-III genes were demonstrated in most of the isolates with HLR to streptomycin, gentamicin and kanamycin, respectively. The ermB and tet(M) genes were detected in 95% and 92% of erythromycin- and tetracycline-resistant isolates, respectively.
Conclusions: Differences in antimicrobial resistance percentages were observed among faecal enterococci of different origins, being those recovered from pigs the most resistant to tetracycline, erythromycin and streptomycin. The normal microbiota of healthy humans and animals represents a considerable reservoir of antimicrobial resistance genes.

P1194 **MRSA of clonal lineage ST398 in clinical isolates in Austria**

K. Krziwanek, S. Metz-Gercek, H. Mittermayer (Linz, AT)

Objectives: Traditionally, meticillin-resistant *Staphylococcus aureus* (MRSA) is a problem of infection control in hospitals, but since the detection of MRSA in the community and in animals it has received a new focus. In the present study we aimed at identifying MRSA strains of clonal lineage MLST 398 in clinical isolates and at looking for possible associations with animals as well as the magnitude of clinical relevance.
Methods: We investigated all MRSA-isolates detected between January 2006 and November 2007 in Upper Austria (one of the nine federal provinces in Austria) by PFGE, spa-typing and MLST typing in clinical isolates. The resistance of these strains to ciprofloxacin, clindamycin (CLI), doxycycline (DOX), erythromycin (ERY), fosfomycin, fusidic acid, gentamicin, moxifloxacin, mupirocin, rifampicin and vancomycin was determined using the Etest® method. Furthermore demographic information and data from patient histories were collected and interpreted by infection control teams in hospitals as well as physicians in outpatient care.
Results: During a period of 2 years we identified 756 patients colonised/infected with MRSA. In 12 patients (8 male, 4 female; median age 58 years, range 1–81) we identified MRSA of clonal lineage ST398 and of spa types t011, t034 and t2346. None of the strains harboured the PVL gene. The isolates were obtained from chronic wounds (6), eye (1) or nose/throat/trachea (3). 8 of these patients were colonised, 2 were infected with MRSA ST398, and of 2 the status was unknown. 6 isolates were resistant to CLI, ERY and DOX, 5 isolates were resistant to only DOX, and 1 isolate was fully susceptible. Epidemiological links to pig farming could be confirmed in 7 patients, and links to farming in 4 patients.
Conclusions: Similar to other countries, also in Austria, MRSA of clonal lineage ST398 is associated with animal contact. There are obvious signs that transmission of MRSA between humans and animals, especially pigs, occurred. We only investigated clinical isolates, however, we presume that MRSA colonisation might be more common in the general population. Further investigations to determine the circumstances and ramifications of transmission from animals to humans need to be performed.

P1195 **Prevalence of pig-associated meticillin-resistant *Staphylococcus aureus* spa types in the German EUREGIO Twente/Münsterland**

R. Köck, A. Mellmann, B. Middendorf, C. von Eiff, K. Becker, F. Kipp, M.G.R. Hendrix, A.W. Friedrich (Münster, DE; Twente, NL)

Objectives: Recent studies indicated that pig-farming is a risk factor for MRSA-colonisation in patients admitted to Dutch hospitals. Pig-related MRSA mostly belonged to *Staphylococcus aureus* protein A (spa) type t011 and its close relatives (t034, t108). Until now, MRSA t011 were rarely found among patients in German hospitals. Since in the EUREGIO Twente/Münsterland pig-farming has a high socio-economic impact, we raised the question how many patients carry MRSA t011 in the German

part of the EUREGIO and asked whether these patients can be identified by screening for classical nosocomial MRSA risk factors.
Methods: In November 2006, all patients admitted to 39 hospitals in the German part of the EUREGIO Twente/Münsterland were screened by nasal swabbing. Risk factors for MRSA carriage were assessed including previous MRSA carriage, contact to MRSA patients, antibiotic prescription, hospitalisation during the past six months, direct transfer from a nursing home or from hospitals, presence of catheters, skin lesions or combustions, chronic need of healthcare and haemodialysis.
All MRSA were spa typed and clustered in spa clonal complexes (spa-CCs) using the Based Upon repeat pattern (BURP) algorithm. Chi-square test or Fisher's exact test were used for analysing differences in the distribution of risk factors and patient population. A p-value <0.05 was considered statistically significant.
Results: Screening yielded a MRSA prevalence of 1.7 MRSA/100 screenings. Among 354 MRSA, 62 isolates clustered in spa-CC011 (17.8%) comprising t011, t034, t108, t567, t1451, and t2011. 286 MRSA (82.2%) clustered in other spa-CCs (spa-CCnon011). 55% of all spa-CC011 and 26.6% of all spa-CCnon011 patients lacked any of the risk factors assessed ($p < 0.001$). Chronic need of healthcare ($p < 0.001$), transfer from nursing homes ($p < 0.001$), and catheters ($p = 0.005$) were less frequent among spa-CC011 patients. spa-CC011 was associated to patients admitted to surgical departments ($p = 0.009$) and neurology or psychiatry ($p = 0.02$), but was underrepresented in internal medicine ($p = 0.01$) and geriatric care ($p = 0.009$).
Conclusions: MRSA spa-CC011 are prevalent in most hospitals in the German part of the EUREGIO. Among these, the predominant spa type was t011. Patients found to carry MRSA spa-CC011 were less frequently associated with classical nosocomial risk factors compared to other MRSA patients. Further investigation is needed to assess pig-farming as a potential risk factor for MRSA in the EUREGIO.

P1196 Multicentre in vitro evaluation of Gram-positive micro-organisms in the Netherlands for daptomycin compared with other antibiotics

J.W. Mouton, J.A.J.W. Kluytmans, A.T. Bernards, A. van Mil, A. Voss (Nijmegen, Breda, Leiden, NL)

Background: Daptomycin (DA) is a new lipopeptide recently approved in The Netherlands (NL). In a multi-centre study, we aimed to evaluate the in vitro antibacterial activity of daptomycin and other antibiotics against various Gram-positive micro-organisms.
Methods: 25 laboratories equally distributed throughout the Netherlands were asked to participate in the study. Each lab was asked to collect up to 90 consecutive isolates from clinical samples (patient >72 h in hospital) during a 3 month period (june-sept 2007), 25 *S. aureus* (SA), 25 Coagulase Negative Staphylococci (CNS), 20 enterococci (EN) and 20 *Streptococcus* spp. other then pneumococci (ST). All isolates were required to be from blood, pus, sites normally sterile or wounds; for CNS at least two cultures needed to be positive. A maximum of one isolate per species per patient was allowed. Isolates were identified by participating laboratories using their own standard identification technique. MIC's were determined using Etest on site for DA, vancomycin VA), teicoplanin (TE), linezolid, gentamicin, erythromycin or clarithromycin, penicillin and cefotaxim (ST), ampicillin (EC), moxifloxacin and rifampicin (staphylococci). BHI agar with 2.0 McFarland and 48 h incubation was used for VA and TE, 0.5 McF on Mueller-Hinton and 24 h incubation for the others. The cefoxitin disk method was applied to staphylococci. Control ATCC strains were included. Afterwards, strains were collected by the central lab for further analysis. All strains were retested to VA, TE and DA. EUCAST criteria were used for interpretation. Data were analysed using WHONET 5.4.
Results: 1709 strains were collected, 525 SA, 427 CNS, 394 EC, and 363 ST. MIC50's for daptomycin were 0.38, 0.5, 1.5 and 0.125 mg/L and MIC90's 0.75, 1, 3 0.5 mg/L, respectively. 36 CNS had MICs of >1 mg/L for DA. 67 strains were categorised as VISE's based on an increased MIC (TE > 8 mg/L). There was a significant correlation between increased MIC for DA and VA (r=0.42; $p < 0.0001$) and TE (r=0.34; $p < 0.0001$) respectively. VA and TE resistance in enterococci was not observed. Four SA showed a slightly increased MIC (3× MIC=1.5 mg/L; 1× 3 mg/L)
Conclusions: Daptomycin showed excellent activity to these clinical isolates. However, staphylococci with decreased susceptibility to glycopeptides showed higher MICs to daptomycin too, possibly limiting the use of daptomycin in this small subgroup.

P1197 Clonal spread of linezolid and teicoplanin-resistant *Staphylococcus haemolyticus* in intensive care unit patients in a tertiary hospital

A. Rodriguez Aranda, M. Daskalaki, J. Villar, F. Sanz, J.R. Otero, F. Chaves (Madrid, ES)

Objectives: Following the observation of several cases of infections caused by isolates of linezolid and teicoplanin-resistant *S. haemolyticus* (LTRSH) we decided to investigate the epidemiology and clonality of these isolates, and to determine the molecular mechanism of resistance to linezolid.
Methods: Medical records of all patients with LTRSH in the last three years were reviewed. Antimicrobial susceptibility testing was performed with Wider panels (Soria-Melguizo, Madrid, Spain) and minimun inhibition contentrations (MIC) were performed by the Etest method for linezolid, teicoplanin, vancomycin, tigecycline and daptomycin. Molecular characterisation of LTRSH isolates was performed by pulsed-field gel electrophoresis (PFGE) after SmaI digestion. A 420bp Domain V region of the 23S gene was amplified for each isolate and the products were digested with NheI restriction enzyme for detecting the G2576T mutation, which has been associated with linezolid resistance.
Results: Between October 2005 and March 2007 we recovered 22 clinical isolates of TLRSH from 15 patients. The mean age was 56 years (SD 11.75) and 66.7% were male. All patients were diagnosed of LTRSH infections while they were in ICU. Fourteen cases were considered clinical infections: 11 catheter-related bacteraemia and 4 surgical infections. Eleven patients underwent abdominal surgery, including four patients with liver transplantation. All isolates were resistant to meticillin, erythromicin, clindamicin, levofloxacin, rifampicin, trimethoprim-sulfamethoxazole, teicoplanin (range 24–128 mg/L) and linezolid (range 32 to 128 mg/L) and susceptible to vancomycin, tigecycline and daptomycin. PFGE analysis indicated that all isolates belonged to a single clonal group. All linezolid-resistant isolates had the same 23S rRNA mutation in domain V, G2576U, and the incomplete digestion of NheI indicated that not all copies of rRNA genes carried the mutation.
Conclusion: This report documents the spread and persistence of a single clone of multidrug-resistant *S. haemolyticus*, including resistance to linezolid and teicoplanin, in ICU patients. This study confirmed previous reports regarding the importance of the G2576T mutation associated to linezolid resistance in *Enterococcus faecium*, *Staphylococcus epidermidis* and *S. haemolyticus*. The emergence of LTRSH in hospitals has important clinical and epidemiological implications.

P1198 Investigation of the genetic basis of erythromycin resistance in *Staphylococcus aureus*, including MRSA, from Pakistan

F. Ullah, S.A. Malik, J. Ahmed, A.M. Snelling (Islamabad, Peshawar, PK; Bradford, UK)

Objectives: Erythromycin (ERY) is used extensively in clinical practice in Pakistan for skin and throat infections, but little surveillance work has been done to assess the extent of resistance amongst common pathogens. Similarly, there is a paucity of information about the MRSA clones circulating. The aim of this study was to determine the prevalence and mechanisms of ERY resistance amongst *S. aureus* from specimens being processed at a diagnostic laboratory in the North West of Pakistan. Also, to see if there were differences in the extent of ERY resistance between meticillin sensitive (MSSA) and resistant (MRSA) strains.
Methods: Sequential isolates of *S. aureus* were collected from wounds and burn/skin infections of in- and out-patients at a tertiary care hospital

in Peshawar. Isolates were identified by standard methods, including PCR for mecA/nuc genes to confirm MRSA, which were also ribotyped. MIC profiles for commonly used antibiotics were determined using CLSI criteria. Presence of erm(A), erm(B), erm(C) and msr(A) genes was determined by PCR.

Results: Of 133 isolates of *S. aureus* collected, 59 (44.4%) were resistant to ERY, with MIC values ranging from 8 to >1024 mg/L. Just 3.3% (n = 3) of the 70 MSSA were resistant, while in contrast, of the 63 MRSA strains, 41.3% (n = 35) were ERY-R. The most common resistance gene detected amongst the ERY-R strains was erm(A) (44.1%), followed by erm(C) (42.3%), msr(A) (8.4%) and erm(B) (5%). No strain carried multiple genes. Eight ribotypes (A to H) of MRSA were present: erm(A) was found in ribotypes A, B and C, erm(C) was found in ribotypes D, E and F. The erm(B) +ve strains were restricted to ribotype G, and msrA to ribotype H. Overall, ERY-R strains of MRSA were generally co-resistant to ciprofloxacin (86.8%), gentamicin (86.8%) and tetracycline (83.6%). However, resistance amongst such strains to chloramphenicol and fusidic acid was much lower (20% and 16.3% respectively).

Conclusion: ERY-R was surprisingly rare amongst skin isolates of MSSA from this area, and thus this antibiotic may still be useful for treating infections if MSSA status is confirmed. Amongst the MRSA, ERY-R is common, mediated mostly by erm(A) and erm(C), and the resistance genes map to the clonal lineages. Where the skin infection is due to an MRSA, topical fusidic acid may still have utility in this area of Pakistan.

P1199 Distribution of macrolide resistance genotypes and phenotypes among *Staphylococcus aureus* and coagulase-negative staphylococci, Italy

G. Gherardi, L. De FLorio, G. Lorino, L. Fico, G. Dicuonzo (Rome, IT)

One-hundred macrolide-resistant staphylococcal isolates from clinically relevant infections in Italy during a 19-months period were studied to determine macrolide resistance genotypes and phenotypes. Macrolide resistance phenotypes were performed by using the triple-disk induction test with 15-μg ERY disk, 2-μg CLI disk, and 15-μg TEL disk. Four distinct resistance phenotypes were observed among 100 erythromycin-resistant isolates: the cMLSB phenotype (24 isolates); the iMLSB phenotype (41 isolates); the MS phenotype (3 isolates); and the iMTS phenotype (erythromycin-induced telithromycin resistance) (32 isolates). All isolates with MS and iMTS phenotypes were msrA-positive, whilst all isolates with MLSB phenotype were erm-positive. ermC gene predominated within erythromycin-resistant *S. aureus* isolates with iMLSB phenotype, while ermA gene was present in all but one *S. aureus* isolates with cMLSB phenotype. The msrA gene was found in only one *S. aureus* isolate. Among erythromycin-resistant CoNS isolates half of the strains showed the iMTS or MS/msrA association. ermC gene was present in all but 2 erm-positive CoNS isolates. Among 76 erythromycin-resistant isolates studied by PFGE an high genetic heterogeneity was observed, with both independent acquisition of macrolide resistance genes and spread of specific resistant clones as mechanisms responsible for occurrence of macrolide resistance. To our knowledge, it is the first report on the prevalence of the erythromycin resistance phenotypes and genotypes among staphylococcal clinical isolates in Italy.

P1200 Distribution of mefE and ermB in macrolide-resistant *Streptococcus pneumoniae* isolated from nasopharynx of healthy children

I. Korona-Glowniak, A. Malm (Lublin, PL)

Objectives: The vast use of macrolides has been connected with increased prevalence of macrolide-resistant strains of pneumococci. In many European countries, the rate of pneumococcal resistance to macrolides has exceeded the level of resistance to penicillin G. More than 20% rates of resistance to erythromycin are reported in France, Spain, Poland, Greece, and Portugal. Macrolide resistance is mediated by two main mechanisms in pneumococci. The most common mechanism is mediated by methylase encoded by the erm(B) gene. Ribosome methylation causes reduced binding of and coresistance to macrolide, lincosamide, and streptogramin B (MLS) antibiotics. In streptococci MLS resistance can be expressed either constitutively (cMLS phenotype) or inducibly (iMLS phenotype). Macrolide efflux mechanism is mediated by an efflux pump encoded by mef(E) gene. It is associated with M phenotype characterised by resistance to 14- and 15-membered macrolides only. We selected erythromycin-resistant strains of *S. pneumoniae* isolated from nasopharynx of healthy children and tested them for resistance phenotype and analysed for genes responsible for macrolide resistance.

Methods: 113 erythromycin-resistant *S. pneumoniae* strains were tested for resistance phenotype by erythromycin-clindamycin double-disk (ECDD) test. The presence of erythromycin resistance genes was investigated by PCR. Primer pairs specific for detection of erm(B) and mef(E) and amplification and electrophoresis of PCR products were carried out by Sutcliffe et al. (AAC 1996).

Results: Erythromycin-resistant *S. pneumoniae* strains belonged mainly to 19F (55%) and 6B (37%) serotypes and remaining single strains belonged to 23F, 14, 15B, and 23A. 74% pneumococcal strains were also non-susceptible to penicillin. All 113 erythromycin-resistant strains tested using the ECDD assay were assigned to the cMLS phenotype. iMLS and M phenotypes were not found by this method. All strains had the erm(B) gene and 29 (25.7%) strains showed both erm(B) and mef(E) genes. There were no correlation between coexisting erm(B) and mef(E) and serotypes or resistance to other antibiotics, including penicillin.

Conclusion: The predominance among erythromycin-resistant pneumococci of isolates carrying the erm(B) gene over those carrying the mef(E) is consistent with result of other studies from European countries. Prevalence of isolates with combined mef(E) and erm(B) genotypes is increasing particularly in children.

P1201 Population structure of erythromycin-resistant *Streptococcus pneumoniae* invasive isolates recovered in a Spanish hospital in Madrid

E. Gomez G. de la Pedrosa, E. Loza, R. del Campo, A. Fenoll, F. Baquero, R. Cantón (Madrid, ES)

Objectives: To analyse the population structure of erythromycin resistant *Streptococcus pneumoniae* isolates and further characterisation of mef-positive isolates recovered from blood cultures in a hospital in Madrid. Prevalence of associated resistance phenotypes and genetic determinants were also screened as well as the antimicrobial co-resistances.

Methods: Among all 334 *S. pneumoniae* invasive isolates recovered from 2000 to 2006 in our hospital a PCR assay was performed to identify erythromycin resistance genes [erm(B) or mef]. A multiplex-PCR was designed to distinguish between mef(A) and mef(E). Susceptibility testing was performed by the standard microdilution technique (CLSI) and resistance phenotypes by the double disk diffusion assay. Population structure was studied by serotyping and SmaI-PFGE among erythromycin resistant isolates and also by MLST within mef-positive isolates.

Results: A total of 68 erythromycin resistant isolates (20.3%) were obtained, with no significant (Mantel Haenszel test) trend to decrease over the studied period. Overall resistance values among these isolates were: penicillin, 61.7%; cefotaxime, 8.8%; clindamycin, 61.7%; tetracycline, 78%; and 1.5%, levofloxacin. Resistance gene distribution were: erm(B), 75.0%; erm(B)+mef(E), 16.2%; mef(E), 7.3%, and mef(A), 1.5%. The iMLSB and cMLSB phenotypes were observed in 75.0% and 16.2% of isolates, respectively, whereas the M phenotype was observed in 8.8%. Serotype 14 (20.5%), 6B (13.2%), 19A (13.2%), 19F (7.3%), 6A (5.8%), and 4 (5.8%) were predominant. Most isolates belonging to the same serotype showed different PFGE pattern. Spain^{6B-2}, Sweden^{15A-25} and Tenesse$^{14-18}$ international multi-resistant clones were found within the erm(B)+mef(E) positive isolates. England$^{14-9}$ was represented by two isolates, one carrying the mef(A) gene and the other one the mef(E) gene. Interestingly, Spain^{9V-3} clone

were both represented in two mef(E) positive isolates and additionally in three erm(B)+mef(E) positive isolates.
Conclusions: Erythromycin resistance in our invasive isolates remains high mainly due to the presence of erm(B) gene. Nevertheless a high proportion of these isolates also harboured the mef gene endowing the iMLSB phenotype. A polyclonal population structure was found in our mef positive *S. pneumoniae* isolates which included international multirresistant clones.

P1202 Conjugative transposon Tn5253 of *Streptococcus pneumoniae*

F. Iannelli, F. Santoro, M. Oggioni, G. Pozzi (Siena, IT)

Objectives: The conjugative transposon (CT) Tn5253, also called (cat tet)6001, is a genetic element which integrates at a specific site into the chromosome of *Streptococcus pneumoniae*. Tn5253 was originally found in *S. pneumoniae* strain BM6001, a serogroup 19 clinical isolate resistant to chloramphenicol and tetracycline. Tn5253 was found to carry resistance genes tet(M) and cat, and could be trasferred by conjugation to the chromosomes of other pneumococcal strains and of other bacterial species including *Streptococcus pyogenes*, *Streptococcus agalactiae*, *Streptococcus gordonii*, and *Enterococcus faecalis*. Aim of this study was to obtain the complete nucleotide sequence of Tn5253, as a contribution to our understanding of the resistance-carrying mobile genetic elements that are found in the genomes of *S. pneumoniae* isolates.
Methods: The complete nucleotide sequence of Tn5253 was obtained by using as a template different PCR fragments (size varies between 0.3 to 22 kb).
Results: Sequence analysis showed that Tn5253 is 64,513 bp in size, with 78 ORFs. Tn5253 was also found to contain two distinct genetic elements integrated: (i) a copy of Tn5251, of the Tn916-Tn1545 family of tet(M)-carrying CT, and (ii) a copy of pC194, a cat-containing plasmid of *Staphylococcus aureus*. Tn5251 was found to be 18,039 bp in size and 99% identical to Tn916 of *Enterococcus faecalis*. The copy of pC194 found in Tn5253 (called pC1945253) was 2816 bp in size and, compared to pC194, had a deletion of 93 bp involving the plasmid replication origin. Conclusion.
These data represent the basis for a detatiled analysis of the repertoire of mobile genetic elements in *Streptococcus pneumoniae*, and for a functional analysis of the conjugation properties of this element.

P1203 Distribution of the macrolide resistance genes mefA, mefE, and erm in *S. pneumoniae* and *S. pyogenes* in Germany from 2005 to 2006

C. Bley, M. van der Linden, R. Reinert (Aachen, DE)

Objectives: *Streptococcus pneumoniae* is the major cause for many childhood diseases like respiratory tract infections, acute otitis media and community-aquired pneumonia. Resistance of S.pneumonia and *S. pyogenes* to macrolide antibiotics has become an increasing problem worldwide due to the spread of the resistance genes mefA, mefE and ermB. Both mef genes encode an efflux pump, resulting in low level resistance to macrolides (M-phenotype). The sequences of mefA and mefE are almost identical, but the genes are carried on different genetic elements: Tn1207.1 and MEGA respectively, that might give rise to differences in clonal spread. ErmB encodes an rRNA methylase which modifies the macrolide binding site in the ribosome, thus giving rise to high level resistance (MLSB-phenotype). We investigated the macrolide resistance markers in Germany (2005–2006), with special emphasis on the distribution of mefA and mefE.
Methods: *S. pneumoniae* and *S. pyogenes* isolates were collected between 2005 and 2006 as part of the national surveillance programs of the German National Reference Centre for Streptococci (GNRCS). Clarithromycin MICs were determined with the microdilution method according to the CLSI criteria. A multiplex PCR was performed to distinguish between mefA and mefE and a separate PCR was used to detect the ermB gene. Multilocus sequence typing (MLST) was performed according to standard methods.
Results: Between 2005 and 2006 the GNCRS received 2065 *S. pneumoniae* and 330 *S. pyogenes* isolates from children and adults from all over Germany. A total of 481 *S. pneumoniae* and 26 *S. pyogenes* isolates were macrolide resistant and of 446 and 20 of these isolates the resistance markers were determined. Among the *S. pneumoniae* isolates the main resistance marker was mefA (55%), followed by ermB (26%) and mefE (11%). 4% were mefA+ErmB, 4% mefE+ermB and 0.4% carried neither mef nor ErmB. Among the *S. pyogenes* isolates 45% were mefA and 55% erm. MLST analysis indicated a clonal dissimination of both mefA and mefE determinants.
Conclusion: mefA is the most common macrolide resistance marker in *S. pneumoniae* and *S. pyogenes* in Germany. This is in contrast to countries like Spain, Canada and the USA, where mefE is far more prominent.

P1204 Analysis of structural alterations in the regulatory region of the erm(TR) gene of *Streptococcus agalactiae* with constitutively expressed MLSB resistance

M.E. Llaneza, C. Seral, S. Algarate, A. Martínez, C. García, M.C. Rubio, R. Gómez-Lus (Zaragoza, ES)

Objectives: The methylases conferring MLSB resistance are encoded by erm(TR) and erm(B) in *Streptococcus agalactiae* (GBS). The regulatory region of the erm(TR) gene consists of two leader peptides (LP1 and LP2) containing a number of inverted repeats that can act in attenuator regulation, analogous to that found in erm(C). Little has been published regarding the regulation in GBS of erm(TR). The purpose was to study the regulatory region in GBS clinical isolates harbouring constitutively expressed erm(TR) gene.
Methods: Antimicrobial susceptibility testing to MLSB antibiotics and identification of resistance phenotype were performed by broth microdilution (CLSI guidelines) and triple disk diffusion methodology, respectively. Ten isolates, with constitutively expressed MLSB resistance encoded by erm(TR), were selected among 141 MLSB resistant GBS collected from vaginal swabs obtained from 2002 to 2004 by our Clinical Laboratory (Hospital Lozano Blesa, Zaragoza, Spain). The erm(TR) regulatory region of these isolates were amplified from chromosomal DNA. Therefore, we determined the nucleotide sequences and deduced amino acid sequences of erm(TR) regulatory region. Pulsed-field gel electrophoresis (PFGE) analysis was performed on the 10 GBS isolates following Sma1 digestion.
Results: GBS isolates selected expressed a resistance cMLSB pattern characterised by high resistance to clindamycin (range >64 mg/L) and low resistance to erythromycin (range 8–16 mg/L). Sequencing of the attenuator region upstream erm(TR) showed six different point mutations (C57U) (G98A) (A137C) (C170U) (G205A) (G205T) and only one 863 bp insertion were identified. Most of the changes were found in the ORFs of the second leader peptide (LP2), mainly due to the mutation (A137C). One of the amplification product was greater than expected and carried an insertion of 863 bp in position 121 of LP2. Sequencing of the insertion fragment showed 98% identity with insertion sequence IS1381. Analysis by PFGE revealed that three isolates were closely related (homology >80%).
Conclusions: This study showed that mutations and insertions in the regulatory regions of erm(TR) can be correlated to constitutive MSLB expression due to the destabilisation of the stem-loop that would lead to the translation of the erm(TR) gene and results in increased or constitutive expression of erm(TR) gene.

P1205 Molecular epidemiology and macrolide resistance traits of *Streptococcus agalactiae* and *Streptococcus uberis* from bovine mastitis

M. Rato, R. Bexiga, S.F. Nunes, D. Rolo, L.M. Cavaco, C.L. Vilela, I. Santos-Sanches (Caparica, Lisbon, PT)

Objectives: To evaluate the clonality and resistance patterns against macrolide and tetracycline of *Streptococcus agalactiae* (GBS) and of *Streptococcus uberis* (SU), both important contagious and environmental pathogens in bovine mastitis, in order to formulate effective mastitis control programs for dairy herds.

Methods: A total of 60 GBS and 30 SU field isolates were recovered among 459 milk samples from mastitis quarters of 377 bovines in 12 Portuguese dairy farms, during a national survey performed in 2002–03, and were characterised by pulsed field gel electrophoresis (PFGE) with computer-assisted DNA-band analysis. GBS and SU representative isolates of different PFGE sub-types were analysed by multilocus sequence typing (MLST). Resistance against macrolides (erythromycin-E), lincosamides (pirlimycin-PRL) and tetracycline-T and the macrolide-lincosamide resistance phenotypes (M/cMLS/iMLS) were evaluated by disk diffusion. The macrolide and tetracycline resistance genes mef(A), erm(A), erm(B), tet(M), tet(O), tet(W), tet(L), tet(Q), tet(K), tet(S) were searched for by PCR among isolates of both species.

Results: A total of 10 PFGE clusters comprised 77% of the GBS and four PFGE clusters comprised 53% of the SU and almost all were found to be herd-specific. The GBS were clustered in ST-2 and ST-61 lineages previously described among human isolates of GBS (according to the *S. agalactiae* MLST database), while the SU isolates were included into 11 novel lineages (seven of which consist of new alleles) clustered into three clonal complexes, ST-143, ST-86 and ST-5, known to include bovine isolates from several geographic locations. Co-resistance to E and T was found in both GBS (17%) and SU (27%) belonging to several clones or lineages and most GBS were cMLS erm(B)$^{+}$/tet(O)$^{+}$/tet(K)$^{+}$ while most SU were cMLS-erm(B)$^{+}$/tet(O)$^{+}$. SU isolates susceptible to E and resistant to PRL and T carried the tet(S).

Conclusions: The results suggested contagious and environmental sources of SU infections and extensive cow-to-cow transmission of GBS. The detection of the same macrolide and tetracycline resistance determinants among isolates of both species suggests vertical and horizontal transmission of these genes. A same phenotype of susceptibility to macrolides and resistance to lincosamides, previously detected in GBS of human origin – LSA phenotype, was found in SU bovine isolates.

P1206 mef(E) is present in *Streptococcus pyogenes* and can be transferred by conjugation

M. Del Grosso, G. Barbabella, R. Camilli, R. Creti, J. Blackman Northwood, D.J. Farrell, A. Pantosti (Rome, IT; London, UK)

Objectives: Efflux transport system, associated with the mef gene, confers resistance to 14- and 15-membered macrolides (M phenotype) in streptococci. In *S. pyogenes*, mef(A) was found to be carried by conjugative genetic elements, whereas a genetic element carrying mef(E) in *S. pyogenes* has not been described. Among a global collection of *S. pyogenes* clinical isolates, strains carrying mef(E) were identified. The aim of the study was to characterise the element carrying mef(E) in *S. pyogenes*.

Methods: Among 17 *S. pyogenes* isolates which were positive for the presence of mef(E), one isolate from the United States (MB56SPYO9) was examined: PCR assay and sequencing of mef, PCR mapping targeting mega, MLST and emm typing were performed. Conjugation experiments were carried out by using both *S. pyogenes* and *S. pneumoniae*, as recipient strains. Transconjugants were analysed by PFGE followed by hybridisation with mef(E) probe.

Results: In *S. pyogenes* MB56SPYO9 belonging to sequence type ST36 and emm type 12, the presence of mef(E) was confirmed by sequencing. By PCR mapping targeting mega, the fragments obtained were of the same size as those obtained with a control strain. This indicates the presence of mef(E) in a mega element. By conjugation, the erythromycin resistance was transferred from the donor MB56SPYO9 to both *S. pyogenes* and to *S. pneumoniae* recipient strains. SmaI-restricted genomic DNA from the donor, the recipients, and the transconjugants were examined by PFGE. Analysis of the profiles showed the appearance of a novel band in the transconjugants, suggesting the acquisition of an approximately 50 kb DNA fragment by conjugation. Hybridisation assay by using mef(E) probe revealed that this fragment included mef(E).

Conclusions: In *S. pyogenes*, mef(E) is carried by mega and is included in a large conjugative genetic element. Further investigations will be done to characterise this element.

P1207 Phenotypic and genotypic characterisation of group A *Streptococcus* clinical isolates: antimicrobial resistance patterns, macrolide-resistance genes and emm typing

A. Michos, C. Bakoula, M. Braoudaki, F. Koutouzi, A. Pangalis, H. Kirikou, V.P. Syrioupoulou (Athens, GR)

Objectives: The aim of the present study was to characterise phenotypically and genotypically clinical isolates of group A streptococci (GAS) from a paediatric population in our geographic region

Methods: A total of 1160 GAS clinical isolates were collected during 1/2003–12/2006. Susceptibility testing was performed using standard disk diffusion and Etest methods. Mechanism of macrolide resistance was phenotypically determined using double-diffusion disk test. The presence of mefA, ermA and ermB genes were detected by PCR. emm types were identified by amplification and sequencing.

Results: The average rates of resistance to erythromycin, clindamycin, azithromycin, tetracycline and chloramphenicol were 14.9%, 0.9%, 14.9%, 11.46%, 0.6%, respectively. A significant increase in macrolide resistance was noted from 12.1% in 2003 to 18.8% in 2006 ($p=0.02$). None of the isolates exhibited resistance to penicillin, ceftriaxone, rifampicin, or ciprofloxacin. Among the erythromycin resistant isolates, 93 (53.7%) expressed the M phenotype, 70 (40.5%) the iMLSB and 10 (5.8%) the cMLSB phenotype. Overall, 93 (53.7%) of the isolates harboured the mefA gene, 70 (40.4%) the ermA and 10 (5.8%) the ermB. The most prevalent emm types were 12, 77, 4 among macrolide resistant and 1, 12, 28 among macrolide susceptible isolates. emm types 77, 4, 12, 28 accounted for 75% of invasive isolates and emm types 12, 1, 4, 28, 77 accounted for 75% of non invasive isolates. emm type 77 was found significantly more frequent among invasive isolates ($p=0.02$). GAS vaccine (in clinical trials) encompasses almost 80% of emm-types detected in our study.

Conclusions: Macrolide resistance rates are increasing among GAS in our region. The predominant determinants conferring resistance to macrolides were the mefA and ermA genes. The emm types included in GAS vaccine cover 80% of streptococcal isolates causing infections in Greece. Continuing surveillance studies are needed to determine the stability of the trends reported above and to guide therapy and development of vaccine strategies.

P1208 Decrease in macrolide resistance and clonal instability among *Streptococcus pyogenes* in spite of increased macrolide consumption

C. Silva-Costa, F.R. Pinto, M. Ramirez, J. Melo-Cristino (Lisbon, PT)

Objectives: Although macrolide resistance has remained stable in Portugal during 1998–2003 (27%), a rapid inversion of the dominant phenotypes was noted, with a sharp decrease in the proportion of isolates presenting the MLSB phenotype and a concomitant increase in the isolates presenting the M phenotype. To gain further insights into the changes in overall macrolide resistance, in fluctuations of macrolide resistance phenotypes and in the clonal structure of the macrolide resistant population, we undertook the phenotypic and molecular characterisation of 156 macrolide resistant GAS isolated in 2004–2006.

Methods: Antimicrobial susceptibility testing and macrolide resistance phenotype were performed by disk diffusion. All the macrolide-resistant isolates were further characterised. Macrolide and tetracycline resistance genotypes were determined by PCR. A combination of T typing, emm typing, pulsed-field gel electrophoresis (PFGE) and multilocus sequence typing (MLST) was used. The Bionumerics software was used to create UPGMA dendrograms of SmaI/Cfr9I fragment patterns. The Dice similarity coefficient was used with optimisation and position tolerance settings of 1.0 and 1.5, respectively. PFGE clusters included isolates with ⩾80% relatedness on the dendrograms. MLST analysis was performed on representatives of each lineage.
Results: During the three years of the study, the overall rate of erythromycin resistance was lower than the one documented previously, and a decrease in the prevalence of isolates presenting the M phenotype was also noted. PFGE and MLST were highly concordant and identified eight major lineages, containing 139 isolates (89%). Molecular characterisation revealed a very diverse population. Some of the PFGE clusters identified had already been found, but others were described for the first time in Portugal.
Conclusion: A decline in macrolide resistance in *S. pyogenes* was noted, in spite of high macrolide use, and these changes were accompanied by clonal variations. The emergence of clones not detected previously, the change in the prevalence of the clones already described or even the disappearance of some clones resulted in marked differences in the clonal composition of the population of macrolide-resistant GAS in Portugal.

P1209 Emergence of moxifloxacin resistance in Swedish epidemic *Clostridium difficile* isolates in the era of the global NAP1/027 epidemic

T. Norén, T. Akerlund, J. Andersson, I. Alriksson, M. Unemo (Örebro, Solna, SE)

Objectives: In recent years global outbreaks of *Clostridium difficile* associated diarrhoea (CDAD) in the western world involve the epidemic strain of *C. difficile* characterised as PCR ribotype 027 and PFGE type NAP1. Increased infection rates and more severe cases of diarrhoea have featured these epidemics. Use of modern fluoroquinolones (moxifloxacin/gatifloxacin) has been thought to be the epidemic trigger selecting moxifloxacin resistance NAP1/027 isolates. In Sweden the epidemic strain SE17 (Serogroup C, PCR ribotype 012) has been dominant in nosocomial clustering. Retrospectively only three historical isolates of NAP1/027 have yet been found in Sweden without increased morbidity or epidemic clustering. Prior to 2004 both these Swedish NAP1/027 strains and the SE17 have been fully susceptible to moxifloxacin as opposed to the epidemic NAP1/027 being resistant. Hence we used moxifloxacin resistance as a surveillance marker when testing clinical isolates 2004 (n = 300) and 2007 (n = 300) for any emergence of moxifloxacin resistance.
Aim: To determine whether moxifloxacin resistance is a useful general marker of epidemic isolates or exclusively a screening tool of NAP1/027.
Material and Methods: MIC determination. Anaerobically cultured isolates were suspended in nutrient broth (Oxoid) to a turbidity of 1.0 and seeded on IsoSensitest agar (Oxoid). Etest strips (Biodisk AB) were placed on top followed by anaerobic incubation at 37°C for 48 h. PCR ribotyping of *C. difficile* isolates. Preparation of template, PCR reaction, separation of PCR products and analysis of banding patterns were according to Stubbs et al (1999, J. Clin. Microbiol. 37:461–463) with minor modifications (Norén et al, 2004, J. Clin. Microbiol. 42:3635–3643) and, accordingly, use of our own nomenclature (prefix SE, Sweden).
Results: In 2004 4% of the clinical isolates showed moxifloxacin resistance (MIC > 32 mg/l) and in 2007 we noted a significant increase of resistant isolates, i.e. the prevalence of resistance was almost six times as high (22.5%). The antibiograms indicated epidemic SE17 uniformly and current nosocomial clusters of disease were located mainly in two geographically distant Dialysis departments and in the Department of Infectious diseases.
Conclusion: Moxafloxacin resistance may not only be a selecting factor and screening marker for NAP1/027 but also useful to detect other virulent *C. difficile* like for example SE17 (Ribotype 012) in Sweden.

P1210 Antibiotic susceptibility pattern and tetracycline resistance of *Lactobacillus* strains of different origin

J. Stsepetova, S. Kõljalg, E. Sepp, K. Lõivukene, E. Songisepp, M. Rätsep, M. Mikelsaar (Tartu, EE)

During the last years substantial attention has been paid to the fact that resistance determinants are widespread among isolates from non-clinical settings. It has been proposed that some food starter cultures and probiotic additives might contain antibiotic resistance genes, particularly to the widely used antibiotic tetracycline.
The aim of the study was to test the possibilities for safety assessment of *Lactobacillus* strains from food by comparing their phenotypic and genotypic antibiotic resistance with reference, intestinal and agricultural strains.
Methods: A total of 44 strains of *L. paracasei* and *L. plantarum* were tested: 25 human (13/12), 4 reference (2/2), 13 silage (7/6) and 2 food industrial (1/1) strains. The MIC values of lactobacilli to ampicillin (AM), gentamicin (GM), streptomycin (SM), erythromycin (EM), tetracycline (TC), chloramphenicol (CL) were assessed according to EU Commission recommendations. Microbial DNA was extracted using QIAamp DNA Kit. Integrase Int1 and tetracycline resistance genes tet(M), (S), (O), (K), (L) were detected by PCR method.
Results: *L. paracasei* and *L. plantarum* strains were susceptible to all tested antibiotics. Compared with *L. paracasei L. plantarum* strains showed higher MIC values to TC($p < 0.001$), EM($p = 0.014$), CL($p = 0.011$) while to AM($p = 0.01$), GM($p < 0.001$) and SM($p = 0.001$) the in former the MIC values were higher than in latter. No differences in MIC values were seen between the food and intestinal & agricultural strains.
All *L. paracasei* and 19/21 *L. plantarum* strains contained IntI gene. The tet genes (M, K, L) alone in different combination were present in 14/23 *L. paracasei* and 16/21 *L. plantarum* strains, respectively. The food *L. paracasei* strain did not contain any tet genes and expressed the low TC resistance (0.19 μg/ml). Tet(K) gene was more frequently detected in *L. plantarum* (16/21 vs 4/23;$p < 0.001$) strains and more widely distributed among human isolates as compared to silage & food strains (15/25 vs. 3/15;$p = 0.012$). The food *L. plantarum* strain did not possess the tet(K) gene but tet(L) and (M) were found resulting in moderate TC resistance (6 μg/ml).
Conclusion: *Lactobacillus* strains of different origin without phenotypical resistance may contain genetic determinants, e.g. integrons and tet-res genes. The comparison of the *Lactobacillus* food strains with reference, intestinal and agricultural strains by phenotypic and genotypic antibiotic resistance methods enables to assess their safety for commercial use.

ESBLs and other β-lactamases – Part 2

P1211 Plasmid-encoded and class 3 integron-associated extended-spectrum β-lactamase gene blaGES-1 from *Escherichia coli* in Switzerland

L. Poirel, T. Bruderer, R. Frei, S. Bernabeu, P. Nordmann (Le Kremlin Bicetre, FR; Basel, CH)

Objectives: *Escherichia coli* isolate TB7 showing an extended-spectrum β-lactamase (ESBL) phenotype was isolated in 1998 from urine of a Swiss patient who had no recent travel history. That strain was resistant to most β-lactams, except piperacillin-tazobactam, cephamycins and carbapenems, with a synergy image between clavulanic acid and extended-spectrum cephalosporins. In addition, a peculiar synergy between cefoxitin and cefuroxime was noticed. The aim of the present study was to identify the ESBL gene and the genetic structures at the origin of its acquisition.
Methods: Genomic DNA *E. coli* TB7 was extracted and used for PCR screening of known ESBL genes. Plasmids were extracted using the

Kieser technique. Mating-out assays were performed using *E. coli* J53 as recipient strain and a selection with ceftazidime (30 mg/L)- and azide (100 mg/L)-containing media. Class 1 and class 3 integron features were mapped by PCR using specific primers.
Results: PCR and sequencing showed that *E. coli* TB7 expressed the ESBL GES-1. Mating-out assays remained unsuccessful but electro-transformation allowed to obtain transformant *E. coli* (pTB7) harbouring the blaGES-1 gene on a 12-kb plasmid. *E. coli* (pTB7) expressed an ESBL phenotype consistent with GES-1 expression, and was resistant in addition to amikacin and kanamycin, but susceptible to all other compounds, including sulfonamides. PCR mapping did not allow identification of class 1 integron features whereas blaGES-1 is usually associated to those structures. Further screening evidenced class 3 integron features, with the Int3 integrase encoding gene located upstream of blaGES-1. Downstream of blaGES-1, a repC gene encoding a putative replicase related to those of broad-host range IncQ plasmids was found.
Conclusion: This study identified ESBL GES-1 in Switzerland for the first time. This is one of the very few reports of acquisition of antibiotic resistance gene mediated by a class 3 integron. Noteworthy, the same blaGES-1-class 3 integron structure association had been evidenced onto a plasmid from a *Klebsiella pneumoniae* isolate recovered in 1999 in Portugal. This finding strengthens the dissemination of GES-1 enzyme worldwide, after its identification in France, Portugal, Argentina and Brazil.

P1212 First isolation of GES extended-spectrum β-lactamases in Enterobactericeae in Belgium

G. Cuzon, P. Bogaerts, T. Naas, C. Bauraing, T. Huang, Y. Glupczynski, P. Nordmann (Kremlin-Bicetre, FR; Mont-Godinne, Brussels, BE)

Objectives: Extended-spectrum β-lactamase (ESBL) producing Enterobactericeae strains are increasing worldwide, mainly due to the emergence of community- and hospital-acquired CTX-M enzymes. ESBLs of the GES-type (also named IBC) are reported in several Gram-negative rods, including *P. aeruginosa*, *E. coli*, and *K. pneumoniae* isolates from Greece, South Africa and Asia. GES-type ESBLs have the property to extend their spectrum of activity against carbapenems by single point mutations. Here, we describe the emergence of GES-6-producing *Citrobacter freundii* and *Enterobacter cloacae* strains in Belgium.
Methods: Clinical isolates were identified using standard microbiological techniques and resistance profile was determined by disc diffusion methods. ESBL genes were sought by PCR and genetic structures surrounding the blaGES-type gene were characterised by cloning, PCR and sequencing. The strains were analysed by plasmid extraction, conjugation and electroporation assays.
Results: In May 2007, a single *C. freundii* and a single *E. cloacae* isolate were recovered respectively from urine and stool specimens of two children hospitalised together in the same paediatric ward at UCL-Saint-Luc hospital, Brussels. The index patient, a 2-year old girl with a diagnosis of congenital stenosis of the biliary tract had been transferred from Israel to Belgium for liver transplantation surgery. Systematic stool screening upon hospital admission revealed the presence of an ESBL-producing *E. cloacae* in this patient. The two strains had a similar resistance pattern, (ceftazidime, amikacin, cotrimoxazole). A synergy was observed by phenotypic confirmatory tests using ceftazidime and ceftazidime/clavulanate double discs. PCR-sequencing revealed the presence of blaGES-6 in both isolates. blaGES-6 was integron-located together with 4 other gene cassettes (aacA4, smr, dhfrI and aadA1). The blaGES gene was inserted onto a conjugative plasmid of 120-kb present in both strains, suggesting in vivo horizontal transfer. The transconjugants displayed an ESBL phenotype but spares C4 cephalosporinases and carbapenems.
Conclusion: This work illustrates the importance of international transfer in the spread of GES-type-producing Enterobacterial strains and suggests that selection of point mutant derivatives of GES-type enzymes, extending their spectrum towards carbapenem is to fear in the next future.

P1213 Molecular characterisation of PER-1 extended-spectrum β-lactamase producing *Pseudomonas aeruginosa* clinical isolates from Romania

M. Straut, S. Cretoiu, C. Dragulescu, B. Lixandru, A.M. Petrescu, M. Surdeanu (Bucharest, RO)

Objectives: The presence of PER-1-producing *P. aeruginosa* isolates in Romania has been already described since 2005. The aim of the present study was to characterise the genetic structures associated with the bla genes harboured by these strains and to establish any clonal relationships between the isolates.
Methods: Analytical isoelectric focusing was used for preliminary characterisation of the β-lactamases expressed by the isolates included in this study. PCR using blaPER-1, blaOXA-2, and blaOXA-10 specific primers, followed by DNA sequencing, was performed in order to identify β-lactamase genes present in *P. aeruginosa* isolates. The occurrence of class1 integrons and Tn1213 transposon was assessed by PCR. Amplicons were further analysed by RFLP (restriction fragment length polymorphism) technique using several combinations of restriction endonucleases. Clonal relationships of PER-1 producing isolates were established by pulsed-field gel electrophoresis (PFGE) analysis of macrorestriction patterns of genomic DNA.
Results: Seventy-four out of 94 ceftazidime resistant clinical isolates examined were PCR-positive for blaPER-1. In all of the studied isolates the blaPER-1 gene was located within a composite transposon Tn1213, bracketed by two different insertion sequences, ISPa12 and ISPa13 (Poirel et al, 2005, Antimicrob. Agents Chemother.: 1708–1713). Additionally, PCR experiments revealed the presence of a pair of class 1 integrons of 3350 bp and 3900 bp among the majority of isolates. The 3350 bp class 1 integron harboured blaOXA-74 gene in the first gene cassette position and the aminoglycoside resistance gene aacA4 in the second place. The blaOXA-2 gene is located within the variable region of the 3900bp integron. The PER-1 producing isolates, originating from nine Bucharest hospitals, clustered into four PFGE types with a high degree of similarity.
Conclusions: PER-1 appears to have a significant presence among the clinical isolates from Bucharest hospitals. PER-1 expression was inferred to be the major source of oxyimino-β-lactam resistance in the examined isolates although they also produced other β-lactamases. Along with some recent reports from other European countries, this work illustrates the ongoing dissemination of organisms with PER-type extended-spectrum β-lactamase.

P1214 Molecular diversity of VEB-1 extended-spectrum β-lactamase-producing *Pseudomonas aeruginosa* in Bulgarian hospitals

E. Dobreva, I. Ivanov, R. Vatcheva-Dobrevska, T. Velinov, T. Kantardjiev (Sofia, BG)

Objectives: *Pseudomonas aeruginosa* causes 10–15% of the nosocomial infections in the world and in the recent years it constitutes for more than 35% of the hospital acquired infections in Bulgaria. The emergence of a large number of VEB-1 ESBL-producing strains raised the need for their molecular characterisation.
Methods: During the years 2000–2007, we examined a total of 111 ceftazidime resistant *P. aeruginosa* from more than 25 hospitals across the country. Identification of the strains and their antibiotic susceptibility were determined by Mini API (BioMerieux, France) and the disc-diffusion method. Specific PCR was carried out for detection of the blaVEB-1 gene. A high resolution multilocus variable number of tandem repeat analysis (MLVA6) modified from a previously reported scheme (Onteniente et al.) was applied for studying the molecular diversity among the isolates.
Results: The presence of the chromosomal gene blaVEB-1 was detected in 73% (81/111) of the isolates. The modified MLVA6 scheme proved highly discriminatory generating a total of 18 genotypes. More than 35% of the isolates were grouped within a single cluster that was prevalent

in the larger city and university hospitals. The other 17 genotypes were presented with a smaller number of isolates (up to six) and often with local distribution.

Conclusions: VEB-1 ESBL-producing *P. aeruginosa* are widespread in Asia but in Europe are reported only in France. Several recent studies highlight their importance among the Bulgarian hospitals and this is the first one to investigate the molecular diversity within a large and representative strain collection. The modified MLVA6 typing scheme accurately discriminated both closely related and unrelated isolates from the same hospital. The provided data suggest that a single cluster is largely distributed among the Bulgarian hospitals.

P1215 Characterisation of an outbreak of nosocomial infection caused by a multiresistant *Acinetobacter baumannii* producing OXA-30 type-β-lactamase

M. Biendo, B. Canarelli, C. Adjide, D. Thomas, S. Castelain, F. Rousseau, F. Hamdad, F. Eb (Amiens, FR)

Objectives: 1. Analysis of the molecular mechanisms involved in the β-lactam resistance of multidrug-resistant *A. baumannii* isolates; 2. the phenotypically and genotypically comparison of clinical and environmental outbreak strains to those obtained before the outbreak.

Methods and Results: Forty multiresistant-drug *A. baumannii* (MDRAB) isolates were consisted of: 8 preoutbreak isolates, 27 clinical and 5 environmental outbreak isolates. Thirty-five clinical isolates were recovered from twenty-six patients admitted to different wards belonging to Amiens University Hospital (AUH), France. MDRAB outbreak strains were observed in the orthopaedic and plastic surgery wards.

The *A. baumannii* isolates were resistant to all of β-lactams tested (MICs, 48–>256 ug/mL) except imipenem (MIC < 4 ug/mL), to aminoglycosides (MICs, 24–>256 ug/mL), and to ciprofloxacin (MIC > 256 ug/mL). All isolates remained susceptible to colistin (MIC < 2 ug/mL).

The frequency of intl1 gene carriage was 96.8% and 37.8% in the outbreak and preoutbreak isolates respectively.

By using isoelectric focusing, three β-lactamases were detected: one produced a band with a pI > 8.0, probably corresponding to a chromosomal AmpC cephalosporinase, the second focused at pI 5.4 and was consistent to TEM-1, the third focused at pI 7.3 and corresponded to OXA-30 type.

blaOXA-30 analysis revealed 3 gene cassettes: intl1 gene with 459-bp coding for an integrase; aacA4 gene with 759-bp encoding a 6′-N-aminoglycoside acetyl transferase and blaOXA-30 gene with 852-bp coding for OXA-30 β-lactamase, with ATG as initiation codon and TAA as termination codon. The deduced amino acid sequence showed an enzyme of 276 amino acids long with Ser-Thr-Phe-Lys at positions 71 to 74, Tyr-Gly-Asn at positions 144 to 146, and Lys-Thr-Gly at positions 215 to 217. blaOXA-30 differed from blaOXA-1 by one base at codon (AGA 131-GGA) resulting in amino acid substitution Arg128-Gly. Pulsed Field Gel Electrophoresis with ApaI showed a single pattern (A) in outbreak and environmental isolates, and 6 unrelated genotypes (B-G) in preoutbreak isolates.

Conclusion: The present work is the first report of *A. baumannii* clinical isolates in France that produce an OXA-30 β-lactamase.

P1216 The first detection of OXA-35 β-lactamase in *Pseudomonas aeruginosa* clinical isolates in Poland and identification of OXA-118, a new extended-spectrum variant of OXA-10 β-lactamase

A.E. Laudy, P. Podbielski, D. Dzierzanowska, S. Tyski, J. Patzer (Warsaw, PL)

Objectives: The OXA-type enzymes are frequently observed in clinical isolates of *P. aeruginosa*. Most of the OXA-type ESBLs are OXA-10 derivatives. Four of these ESBLs (OXA-13, OXA-13–1, OXA-19 and OXA-28) and OXA-35 (restricted-spectrum β-lactamase) differ in one or two amino acids substitutions. Moreover, the structures of class 1 integrons carrying blaOXA-13, blaOXA-13–1, blaOXA-19, blaOXA-28 and blaOXA-35 genes are very similar. Probably OXA-35 is the progenitor of OXA-13-like ESBLs.

The aim of the study was to identify strains producing OXA-10-like ESBLs, among *P. aeruginosa* isolated in two Warsaw's hospitals.

Methods: *P. aeruginosa* strains (n = 30) were isolated from various clinical specimens obtained from patients in A and B Warsaw's hospitals. The presence of ESBLs was detected by a double-discs synergy test. MICs values of antibiotics were determined by agar dilution methods, according to CLSI recommendation. The presence of class 1 integron and genes coding OXA-10-like enzymes was detected by PCR. Gene cassettes were identified by sequencing the obtained amplicons.

Results: The production of ESBLs by 40 *P. aeruginosa* strains was expected in case of resistance to broad-spectrum cephalosporins or aztreonam. Seven of these isolates were found to contain OXA-10-like enzymes located in a class 1 integrons. In 6 *P. aeruginosa* isolates from hospital A the identical structure of integron was identified. This integron contained aac(6′)-Ib and blaOXA-35 genes. The 6 isolates carrying this integron were resistant to cefepime but 5 of them were also resistant to aztreonam and cefotaxime. Among strains from hospital B only in one *P. aeruginosa* isolate, gene coding OXA-10-like enzyme was detected. This gene encoded the new extended-spectrum variant of OXA-10 β-lactamase (named OXA-118). Sequencing showed that OXA-118 was identical to OXA-10 except two amino acids. The clinical isolate producing OXA-118 exhibited the inhibitor-sensitive phenotype (between imipenem and ceftazidime as well as cefepime).

Conclusion: OXA-35 β-lactamase producing *P. aeruginosa* strains were identified for the first time in Poland. The presence of blaOXA-35 gene, within integron in 6 clinical isolates suggests the possibility to create new OXA-13-like ESBLs in Polish hospitals. Moreover, the new extended-spectrum β-lactamase OXA-118, variant of OXA-10, encoded by integron-located gene was identified in *P. aeruginosa* clinical isolate.

P1217 Characterisation of a naturally-occurring oxacillinase from *Achromobacter xylosoxidans*

Y. Doi, L. Poirel, D. Paterson, P. Nordmann (Le K. Bicetre, FR; Brisbane, AU)

Objectives: *Achromobacter xylosoxidans* (previously *Alcaligenes xylosoxidans*) is a Gram-negative, glucose-non-fermenting organism that is increasingly recognised as a nosocomial pathogen. It is reported as variably resistant to β-lactam antibiotics. The aim of the present study was to identify the naturally-occurring β-lactamase gene of *A. xylosoxidans*.

Methods: *A. xylosoxidans* CIP69598 was used for cloning. Genomic DNA was partially digested with Sau3AI and ligated into pBK-CMV followed by electro-transformation in *E. coli* TOP10. Selection of recombinant *E. coli* strains was made on ticarcillin and kanamycin-containing plates. Detection of bla(OXA-114a)-like genes in clinical strains of *A. xylosoxidans* was performed by PCR. Purification of OXA-114a was performed by ion-exchange chromatography. Kinetic parameters of OXA-114a were determined by UV spectrophotometry. Inducibility of β-lactamase production was tested using imipenem and cefoxitin as inducers

Results: A recombinant strain *E. coli* TOP10 (p6S3) was obtained that was resistant to amoxicillin and piperacillin, a phenotype not antagonised by clavulanic acid or tazobactam addition. Plasmid p6S3 possessed a 1,176-bp insert comprising a novel oxacillinase gene encoding OXA-114a. Conserved motifs of serine β-lactamase as well as those specific of oxacillinases were identified. The highest amino acid identity (56%) was observed with a putative oxacillinase of *Burkholderia cepacia*. Kinetic parameters indicated robust hydrolysis of piperacillin and cephalothin, and to a lesser extent, ticarcillin. No hydrolysis of oxacillin or third-generation cephalosporins was observed. Hydrolysis of imipenem was noticed, but did not correlate with the susceptibility of the source strain. Four other OXA-114-like sequences (OXA-114b to OXA-114e) with no more than four amino acids difference between each other, were

identified from the four clinical strains. No induction of OXA-114-like enzymes was detected in clinical isolates.

Conclusion: This study identified a naturally-occurring β-lactamase of *A. xylosoxidans*. It is likely that the contribution of OXA-114-like enzymes in the final β-lactam resistance profile of most *A. xylosoxidans* strains may be secondary given its rather narrow spectrum of activity. This description further strengthens that numerous Gram-negative aerobes harbour oxacillinase genes in their chromosome.

P1218 Spread of diverse AmpC-type-β-lactamase-producing *E. coli* in Madrid, Spain: epidemiology and molecular characterisation

J. Oteo, E. Cercenado, V. Bautista, A. Delgado-Iribarren, B. Orden, J. Campos (Majadahonda, Madrid, ES)

Objectives: Little is known about *E. coli* non-susceptible to 3rd generation cephalosporins but non ESBL-non-producers. The resistance mechanisms and the molecular epidemiology of *E. coli* isolates with antibiotic resistance profile compatible with AmpC-mediated resistance were studied.

Methods: From January-2006 to December-2007 2,349 *E. coli* isolates (only one isolate by patient) non-susceptible to 3rd generation cephalosporins were collected by 2 hospitals and 1 community healthcare centre in Madrid, Spain. Antimicrobial susceptibility testing and ESBL detection was performed following CLSI guidelines. All isolates resistant to cefoxitin, amoxicillin–clavulanic acid, and the 3rd generation cephalosporins with no clavulanic acid synergistic effect were subjected to: a) molecular characterisation of resistance mechanisms by PCR and sequenciation; b) Molecular epidemiology by PFGE after XbaI digestion.

Results: A total of 143 (6.1%) isolates accomplishing the selection criteria; 48 (33.5%) were plasmid mediated AmpC (pAmpC) (45 CMY-2, 2 DHA-1, 1 CMY-4) and 112 (78.3%) were chromosomal AmpC hyperproducers (hAmpC). Seventeen isolates (11.9%) had both mechanisms of resistance pAmpC and hAmpC. In addition, 15 isolates (2 pAmpC and 13 hAmpC) were also ESBL producers, 10 CTX-M-15, 3 CTX-M-14 and 2 CTX-M-9. Mutations in the promoter of chromosomal ampC gene included 2 main profiles: a) –88, –82, –42, –18, –1, +58; detected in 77 (68.7%) isolates; and b) at least 3 of the following: –73, –32, –28, +82; detected in 22 (19.6%). By PFGE, only small clusters were detected affecting mainly CMY-2 and CTX-M-15 producers.

Conclusions: Emergence of the pAmpC CMY-2 and hAmpC in *E. coli* is a relevant problem. In addition, the presence of AmpC production in an epidemic *E. coli* CTX-M-15 producer suggests that the association of both mechanisms of resistance may become an important public health issue.

P1219 Plasmid-mediated CMY-2 AmpC β-lactamase and CTX-M-14 extended-spectrum β-lactamase in *Proteus mirabilis* clinical isolate

S. Simões, L. Lito, J. Melo-Cristino, M. Salgado, A. Duarte (Lisbon, PT)

Objectives: *Proteus mirabilis* is considered one of the most β-lactam susceptible members of the Enterobacteriaceae. Although extended-spectrum β-lactamases (ESBLs) have recently been identified, there are few reports of plasmid-mediated AmpC β-lactamase (PCBL) in *P. mirabilis*. In general, ESBLs confer resistance to oxyimino-cephalosporins but not cephamycins and are inhibited by β-lactamase inhibitors, while PCBLs provide resistance to cephamycins and oxyimino-cephalosporins and are refractory to β-lactamase inhibitors. We report the identification of ESBL and PCBL enzymes in *P. mirabilis* isolate.

Methods: *P. mirabilis* 10830 isolated from neurological abscess was collected in Hospital de Santa Maria at Lisboa. Susceptibility to antimicrobial agents was determined by disk diffusion test, following CLSI guidelines. The conjugation assay was performed using *Escherichia coli* 802 K as recipient strain. PCR experiments were performed using specific primers for ESBL, PCBL, insertion sequences and class 1 integrons. Plasmid extraction was prepared using Kado & Liu method.

Results: The isolate showed resistance to amoxicillin-clavulanate, cefoxitin, cefpime, cefotaxime; intermediate to ceftazidime and susceptible to imipenem and fluoroquinolones. It was observed two plasmids in both *P. mirabilis* and transconjugant *E. coli* P10830, which showed the same susceptibility to β-lactams including cefoxitin.

The double-disk synergy test was observed between clavulanate and cephalosporins (cefepime and cefotaxime). However, a higher synergic effect was observed when the cloxacillin was applied to Mueller-Hinton agar. PCR and sequencing revealed that *P. mirabilis* 10830 clinical isolate and the transconjugant *E. coli* K P10830 harboured CMY-2 AmpC β-lactamase and CTX-M-14 extended-spectrum β-lactamase; A complex class 1 integron containing the blaCMY-2 gene; and the blaCTX-M-14 gene was bracketed upstream and downstream by insertion sequences ISEcp1 and IS903, respectively.

Conclusions: This is the first report of a plasmid that carries both CTX-M-type ESBL and CMY-type PCBL genes. The finding of the coexistence of these genes in such a transmissible plasmid that can propagate in different hosts provides further insight into the mechanisms of transmission of these β-lactamases in Portugal.

P1220 Expression of blaCMY-14 promoted by insertion sequence ISEcp1 in *P. mirabilis* isolates in Greece

I. Galani, M. Souli, Z. Chryssouli, H. Giamarellou (Athens, GR)

Objectives: *Proteus mirabilis* clinical strains with β-lactam resistance phenotype consistent with production of an AmpC-type β-lactamase are isolated with increased frequency in our hospital. The aim of this study was to identify the mechanism of the high-level expression of blaCMY-14 and blaCMY-2 genes which are responsible for this phenotype.

Methods: Sixteen nonreplicate *P. mirabilis* clinical isolates were analysed. Identification and susceptibility testing were carried out following standard procedures. Molecular typing was performed with REP-PCR. β-lactamase production was analysed by isoelectric focusing (IEF). β-lactamase genes were determined by PCR and sequencing. The ISEcp1 element was detected in the 5′-end of blaCMY genes by PCR. Sequencing of the resulting amplicons was performed with the same primers. Sequence similarity searches were carried out with the BLAST program found at the website of the NCBI.

Results: All isolates were resistant to ampicillin, amoxicillin-clavulanate, cefotaxime, ceftazidime, cefoxitin and fluoroquinolones; susceptible to cefepime, aztreonam, piperacillin/tazobactam and carbapenems. Isolates were obtained during the period Oct 2005 to Feb 2007 from urine (3), pus (5), sputum (4) or faeces (colonisers) (4) from inpatients in ICU (7), Internal Medicine department (4) and Surgery department (5). IEF analysis revealed the presence of β-lactamases of pI 5.4 and >8.4. PCR analysis revealed the presence of CMY- and TEM-type genes. Sequencing showed the presence of CMY-14 gene in 14 isolates and of CMY-2 in two isolates. Extensive analysis showed that ISEcp1 was responsible for mobilisation of a transposition unit including itself and blaCMY-14 or blaCMY-2. All isolates carried the ISEcp1 mobile element at the same distance upstream of the blaCMY gene and in four representative isolates the sequences between them were identical. REP-PCR showed that isolates were grouped in two main clones probably related to each other.

Conclusions: CMY-14 reported in Poland was found in *P. mirabilis* isolates resistant to cefotaxime, ceftazidime and cefoxitin in Greece. The putative promoter element of ISEcp1 is necessary for the high-level expression of blaCMY-14 to confer resistance to extended-spectrum cephalosporins. The present study underscores the spread and evolution of the AmpC-producing *P. mirabilis* in our country.

P1221 Prevalence of plasmid mediated AmpC β-lactamases in non-*typhi* salmonella from Ireland

D. Morris, F. Boyle, J. O'Connor, G. Devane, N. DeLappe, G. Corbett-Feeney, M. Cormican (Galway, IE)

Objectives: The genes encoding AmpC β-lactamases occur naturally on the chromosome of several members of the Enterobactericeae with

the exception of *Klebsiella* spp., *Salmonella* spp. and *Proteus mirabilis*. Since the 1980s the occurrence of plasmid mediated AmpC β-lactamases has been reported with increasing frequency. The aim of this study was to determine the presence of plasmid mediated AmpC β-lactamases in non-Typhi *Salmonella* from Ireland.

Methods: The National Salmonella Reference Laboratory (NSRL) of Ireland screens isolates received for susceptibility to a panel of antimicrobial agents including ampicillin, ceftazidime, cefotaxime, and cefpodoxime, in accordance with CLSI disk diffusion methods. Isolates with reduced susceptibility to the expanded spectrum cephalosporins are further screened for susceptibility to cefoxitin and meropenem and ESBL production is confirmed by the CLSI combination disk method using cefpodoxime and cefpodoxime/clavulanate. Isolates resistant to cefoxitin and cefpodoxime/clavulanate were considered suspect AmpC β-lactamase producers. Antimicrobial susceptibility test data for 8216 isolates received between January 1st 2000 and October 31st 2007 was reviewed for suspect AmpC β-lactamase production. Screen positive isolates were examined for the presence of genes encoding 6 phylogenetic groups of plasmid-mediated AmpC β-lactamases using a multiplex PCR assay (Pérez-Pérez & Hanson. J Clin Microbiol 2002, 40: 2153–62). The full coding region of the genes identified were sequenced using specific primers.

Results: Seven isolates were identified as suspect AmpC producers by the screen criteria applied. PCR and sequencing of the full genes confirmed the presence of blaCMY-2 in 3 isolates (2 human isolates of S. Typhimurium isolated in 2007 and 1 human isolate of S. Virchow isolated in 2006) and blaACC-1 in a single isolate of S. Bareilly isolated from seawater in 2000.

Conclusions: This is the first report of plasmid mediated AmpC β-lactamases in non-Typhi *Salmonella* from Ireland.

P1222 Expression analysis of the native ampC gene in Norwegian clinical isolates of *Escherichia coli* with defined ampC promoter mutations and an AmpC-resistance profile

B. Aasnæs, B. Haldorsen, K. Hegstad Dahl, G. Skov Simonsen, A. Sundsfjord, E. Lundblad (Tromsø, NO)

Objective: The objective was to examine native ampC mRNA levels by quantitative RT-PCR (qRT-PCR) in Norwegian clinical isolates of *Escherichia coli* with defined ampC promoter-attenuator mutations and relate those to minimum inhibition concentrations (MICs) of cefoxitin, third generation cephalosporins, piperacillin-tazobactam, and aztreonam.

Methods: The Norwegian Reference Centre for Detection of Antimicrobial Resistance (K-res) received 106 clinical isolates of *E. coli* from different Norwegian laboratories with reduced susceptibility to third-generation cephalosporins without clavulanic acid synergy, from 2003 to 2005. Of these, twelve were non-plasmid mediated blaampC strains, with defined ampC promoter and attenuator alterations compared to the *E. coli* wild-type ampC promoter-attenuator. Expression of the native ampC gene was examined by qRT-PCR. ampC mRNA levels, normalised to the expression of the reference gene gapA, were compared to those in six cefoxitin-susceptible isolates of *E. coli*, including ATCC 25922. MICs were determined by Etest.

Results: The 12 isolates showed a 27 to 380-fold increase in ampC mRNA levels compared to the ampC mRNA level in *E. coli* ATCC 25922. The ampC mRNA levels varied within the different promoter-attenuator mutation groups. A single strain had an ISEc10 element inserted between the –35 and –10 boxes, providing an almost perfect *E. coli* –35 box 17 bp upstream of the endogenous –10 box. This isolate showed a 54-fold increase in ampC mRNA level. The ampC mRNA levels in the five cefoxitin-susceptible clinical isolates of *E. coli* varied from 0.7 to 2.2 fold, suggesting that the mutations observed in these isolates have no or minor effect on transcription of the ampC gene. For the isolates with reduced susceptibility to third-generation cephalosporins we did not observe any significant correlation between ampC mRNA levels and MICs of FOX, CPD, CTX, CAZ, TZP, and ATM.

Conclusions: (i) Clinical isolates of *E. coli* with defined ampC promoter-attenuator alterations overexpressed ampC 27–380-fold compared to *E. coli* ATCC 25922. (ii) We did not find any significant correlation between ampC mRNA levels and MICs of cefoxitin, third generation cephalosporins, aztreonam and piperacillin-tazobactam.

P1223 Wide occurrence of plasmid-mediated AmpC β-lactamase-producing *Escherichia coli*, *Klebsiella* spp., *Proteus mirabilis*, and *Salmonella* spp. isolates in Korea: results of a multicentre survey in 2007

W. Song, J.S. Kim, H. Lee, S.H. Jeong, Y. Uh, S.G. Hong, K. Lee, G.J. Woo (Seoul, Goyang, Busan, Wonju, Seongnam, KR)

Objectives: Plasmid-mediated AmpC β-lactamases (PABLs) are cephalosporinases that confer resistance to a wide variety of β-lactam drugs and that may thereby create serious therapeutic problems. The PABL-producing organisms are a major concern in nosocomial infections and should therefore be monitored in surveillance studies. The present study was conducted to determine the epidemiology and genotypic distributions of PABL-producing isolates in Korea.

Methods: During the period of May to August 2007, a total of 1,350 consecutive and nonrepeat isolates of *Escherichia coli*, *Klebsiella* spp., *Proteus mirabilis*, and *Salmonella* spp. were collected at 12 hospitals in Korea. The 248 (18.4%) cefoxitin non-susceptible isolates tested for multiplex AmpC PCR and DNA sequencing. The PABL-positive isolates were further investigated for antimicrobial susceptibility by broth microdilution methodology and extended-spectrum β-lactamases (ESBLs) by boronic acid disk tests.

Results: PABL producers were found at all the 12 sites in Korea. PABLs were found in 15/577 *E. coli* (2.6%; 9 of DHA-like, 5 of CMY-like, and 1 of ACT-1-like); 152/544 *K. pneumoniae* (27.9%; 149 of DHA-like, 1 of CMY-like, and 2 of ACT-1-like); 6/65 *K. oxytoca* (9.2%; 6 of DHA-like); 3/104 *P. mirabilis* (2.9%; 1 of DHA-like and 2 of CMY-like); and 1/60 *Salmonella* spp. (1.7%; 1 of CMY-like) isolates. One hundred and four of the 152 PABL-producing *K. pneumoniae* isolates (68.4%) coproduced ESBLs. Susceptibilities of the PABL-producing *K. pneumoniae* were as follows: ceftazidime, 3%; cefotaxime, 26%; aztreonam, 26%; cefepime, 79%; imipenem, 99%; gentamicin, 12%; amikacin, 14%; and ciprofloxacin, 11%.

Conclusion: PABL producers were found to be widespread in Korea. A DHA type is the most prevalent enzyme and the DHA-producing *K. pneumoniae* isolates have rapidly increased in Korea. Each of the PABLs is associated with multidrug resistance. Clinical laboratories should be able to detect PABLs to ensure optimal patient care and infection control.

P1224 The association of several amino acid substitutions in the extended-spectrum AmpC β-lactamases from *Escherichia coli* decreases its overall enzymatic activity

S. Le Turnier, F. Eb, P. Nordmann, H. Mammeri (Amiens, Le K.-Bicetre, FR)

Objectives: class C β-lactamases (AmpC) weakly hydrolyse extended-spectrum cephalosporins (ESCs) and carbapenems. Recently, a novel mechanism of resistance, the extended-spectrum AmpC β-lactamases (ESACs), have emerged among enterobacterial clinical isolates. These variants exhibited increased catalytic efficiencies toward ESCs, leading to enhanced MICs of ESCs. The structural modifications responsible for the broadened hydrolysis-spectrum, mainly amino acid substitutions, occurred in secondary structures surrounding the binding site: the helix H-9, the helix H-10, the helix H-11, the R2 loop, and the Omega loop. The aim of this study was to evaluate if the combination of several amino acid replacements in ESACs could further enlarge the hydrolysis spectrum of these β-lactamases.

Methods: Site directed mutagenesis was applied to the ampC EC2 gene that encoded a wild-type cephalosporinase of *E. coli*. The resistance patterns of variants presenting a single substitution at position 219

(Omega loop), 246 (helix H-11), 287 (helix H-9), and 298 (R2 loop) were compared to those of four variants with the following double substitutions: E219K+S287N; S287N+N346I; S287N+E219K; and V298L+N346I.

Results: The single variants S287N and V298L conferred the highest level of resistance towards ESCs, such as ceftazidime and cefepime, whereas the MICs for the single variants E219K and N346I were only slightly modified. All the double variants displayed decreased MICs of ESCs as compared to those of the single variants S287N or V298L. In addition, the MICs of imipenem remained unchanged for all variants as compared to the wild-type *E. coli* reference strain.

Conclusion: Double substitution at critical positions in AmpC β-lactamase of *E. coli* do not provide enhanced spectrum of hydrolysis.

P1225 Presence and epidemiology of the IRT β-lactamases in contemporary *Escherichia coli* isolates in a hospital in Madrid, Spain

O. Martin S. de la Maza, M.I. Morosini, A. Valverde, R. del Campo, R. Cantón (Madrid, ES)

Objectives: Recent data of inhibitor resistant TEM (IRT) β-lactamases are scarce. We determined the presence and epidemiology of IRT β-lactamases in contemporary *E. coli* isolates with reduced susceptibility to amoxicillin/clavulanate (AMC) recovered in our hospital.

Methods: *E. coli* isolates with reduced susceptibility to AMC (MIC ⩾16/8 mg/L) (WIDER System, Fco. Soria Melguizo, Spain) were prospectively collected in our hospital between September-2006 and March-2007. Two additional susceptibility tests, MIC-agar dilution (AMC fixed 2:1 ratio and 4 mg/L-fixed clavulanate concentration) and disc-diffusion were performed. β-lactam susceptibility phenotypes were further analysed and IRTs were characterised by isoelectric focusing, PCR and sequencing. Their population structure (XbaI-PFGE) was also determined.

Results: 152 out of 3,556 (4.3%) *E. coli* isolates (40.2% recovered from hospitalised and 59.8% from outpatients) had reduced susceptibility to AMC (36.2% resistant and 63.8% intermediate, CLSI-2007). Sources of isolation were: urine (73.7%), blood (9.8%), wounds (5.3%), respiratory secretions (4.6%), and others (6.6%). Analysis of the β-lactam-resistance profiles of 99 randomly selected isolates revealed that reduced susceptibility to AMC could be ascribed to penicillinase (TEM-1) hyperproduction (60.6%), extended-spectrum β-lactamase synthesis (15.2%), IRT synthesis (12.1%) or constitutive AmpC overproduction (12.1%). Confirmed IRT-producing *E. coli* isolates (n = 32) were mostly from urine (66.6%). Five (41.7%) isolates were from hospitalised and 7 (58.3%) from outpatients. No significant discrepancies were obtained between the different susceptibility testing methods, although IRT phenotype was better detected with 4 mg/L fixed clavulanate concentration. Molecular characterisation of bla genes revealed that the IRTs were: 4, TEM-30/IRT-2 (pI 5.2); 2, TEM-32/IRT-3 (pI 5.4); 2, TEM-37/IRT-8 (pI 5.2); 1 TEM-33/IRT-5 (pI 5.4); 1 TEM-36/IRT-7 (pI 5.2); 1 TEM-34/IRT-6 (pI 5.4), and 1, TEM-54 (pI 5.4). IRT-*E. coli* had unrelated PFGE patterns.

Conclusion: The IRT-producing *E. coli* isolates recovered in our hospital over a 7-month period, most from outpatients with urinary-tract infections, represent 12.1% of isolates exhibiting reduced susceptibility to AMC. Interestingly, 7 different IRTs were present in non-related isolates suggesting an independent emergence of these TEM variants mainly attributable to antibiotic selective pressure.

P1226 Molecular epidemiology and mechanisms of β-lactam resistance in *Klebsiella pneumoniae* isolates with reduced susceptibility to amoxicillin-clavulanate from a chronic-care hospital

M.O. Pérez-Moreno, M. Cortell, M.J. Centelles, M.I. Llovet, J. Ruiz, A.M. Jardí, M.P. Cid (Tortosa, Barcelona, ES)

Objective: A high rate of decreased susceptibility to amoxicillin-clavulanate (A/C) was noticed amid *K. pneumoniae* isolates from a chronic-care hospital. The aim of this study was to investigate their molecular epidemiology and the mechanisms involved in β-lactam resistance.

Methods: 94 nonrepetitive *K. pneumoniae* isolates recovered between January 2006 and November 2007 from patients admitted to the above institution were included in the study. Susceptibility testing was achieved by microdilution or disk diffusion. The presence of integrons and of oxa-1, tem-1 like, shv-1 like, pse-1 (β-lactam resistance) and aac(6′)-1b (aminoglycoside resistance) genes was investigated by PCR. Epidemiological relatedness among isolates with reduced susceptibility to A/C was studied by REP-PCR.

Results: (a) 46.7% (29/62) and 18.8% (6/32) of isolates collected during 2006 and 2007 were intermediate-resistant to A/C – MIC 16 mg/L. (b) 94.2% (33/35) of these isolates showed a phenotype consistent with production of inhibitor-resistant TEM (IRT) or OXA β-lactamases, since they were fully susceptible to cefazolin; the presence of tem-1 like plus shv-1-like and of oxa-1 plus shv-1-like was demonstrated in 45.5% and 54.5% of them. (c) All oxa-1-positive isolates were additionally resistant to nitrofurantoin, tobramycin (Tob), kanamycin (K), nalidixic acid, ciprofloxacin, chloramphenicol and sulphonamides and harboured aac(6′)-1b, which confers resistance to Tob and K. No integrons could be detected – except for a single isolate with an integron of 0.8 Kb – with 5′CS and 3′CS primers, although amplicons of ca. 0.7 and 1.8 Kb were obtained when using 5′CS together with aac(6′)-1b or oxa-1 specific reverse primers. (d) Four different REP patterns were identified in the 26 strains available for genotyping: RA (8 tem-1 positive isolates); RB (5 tem-1 and 8 oxa-1-positive isolates); RC and RD (four and one oxa-1-positive isolates).

Conclusions: Our findings indicate that the high prevalence of A/C-resistance among *K. pneumoniae* isolates resulted from the spread of three different epidemic clones and was mediated by the production of two kinds of penicillinases poorly inhibited by clavulanate (i.e. OXA-1 and inhibitor resistant enzymes, likely of IRT type), a fact that could be related to the elevated consumption of A/C in the centre. Interestingly, the present results suggest that oxa-1 might be associated with aac(6′)-1b, and perhaps other resistance genes, within a class 1 integron.

P1227 Differentiation between BRO-1 and BRO-2 β-lactamases in clinical isolates of *Moraxella catarrhalis* collected 2002–2003

L.R. Cossins, J. Blackman Northwood, M.A. Khan, J.P. Hays, D.J. Farrell (London, UK; Rotterdam, NL)

Objectives: To determine the presence and incidence of the bro1 and bro2 β-lactamase genes in clinical isolates of *Moraxella catarrhalis* collected in the winter of 2002–2003.

Methods: A novel PCR RFLP method was developed and used to screen 1,449 isolates of *M. catarrhalis* for the presence of either the bro1 or bro2 genes. This was achieved by initially developing primers that hybridised to conserved promoter sequence regions upstream of both genes (BROF – 5′-TRGTGAAGTGATTTTKRRMTTG-3′ BROR – 5′-GCAATTTATTAACTGGATGTA-3′), yielding PCR products differing in size by 21bp (bro1 = 165bp and bro2 = 144bp).

After PCR thermocycling, the resultant amplicon was digested using the restriction enzyme tsp509i, yielding visible fragments of 55bp and 91bp and 91bp alone for bro1 and bro2, respectively. The PCR RFLP products were visualised on a 3.5% agarose gel. During the analysis, sequencing was performed on 2 PCR products from isolates that showed anomalies in their PCR amplification products.

Results: Of the 1,449 isolates tested 1,314 (91%) were positive for bro1 and 65 (4.2%) positive for bro2. Seventy (70) isolates (4.8%) were negative for both genes. A single bro1 isolate had a single nucleotide polymorphism (SNP) at position T30C of the promoter region yielding a PCR RFLP product of 146bp, whilst a second bro1 isolate yielded 3 visible bands of 31bp, 91bp and approximately 150bp.

Conclusions: Consistent with published data, bro1 was found to be the most common β-lactamase type present within our global, clinical *M. catarrhalis* isolates at an incidence of 91%. Also consistent with published data, 5% of our isolates possessed the bro2 gene. Only 1

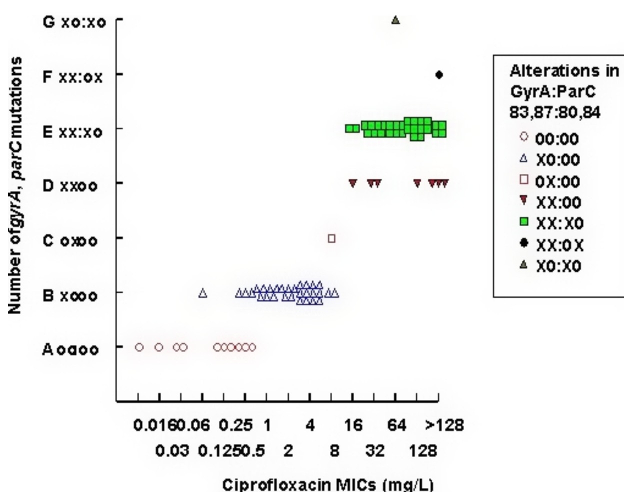
isolate was identified that possessed nucleotide polymorphisms for the restriction enzyme used, mirroring the low frequency of mutation within the promoter regions of bro1 genes. It was found that a PCR RFLP methodology yielded more accurate results regarding the identification of bro1 and bro2 over PCR alone.

Quinolone and fluoroquinolone resistance – Part 1

P1228 Topoisomerase alterations and ciprofloxacin resistance in clinical isolates of *Klebsiella pneumoniae*

S. Aathithan, G. French (London, UK)

Objectives: To determine the frequency and distribution of amino acid alterations in the quinolone binding region (QBR) of GyrA and ParC and the effect of these changes in ciprofloxacin susceptibility amongst 78 clinical isolates of *Klebsiella pneumoniae* showing ciprofloxacin reduced susceptibility or resistance.
Methods: Sequencing of PCR derived amplicons from a 626bp region of gyrA, and a 388bp region of parC covering the extended quinolone resistance-determining regions (QRDR).



Results: There were 19 different combinations of topoisomerase variants amongst the 78 isolates. The most common mutation, in 97% of mutants, occurred at codon 83 in gyrA, mostly resulting in either S83Y or S83F substitutions in GyrA. There was a strong correlation (r=0.90, 95% CI 0.84–0.93) between the number of target alterations (particularly in GyrA) and ciprofloxacin MICs. No target alteration was found in the 6 isolates with only small reductions in susceptibility. 70/78 isolates with greater reduced susceptibility had target alterations: 29 had alterations in S83, and 1 in D87, of GyrA; 39 of the other 40 had different combinations of double or triple alterations in GyrA and ParC; one had S83Y and F147Y alterations in GyrA and ParC, respectively. The figure shows the association between topoisomerase gene mutations and ciprofloxacin MICs. In this figure a circle=isolates with wild-type sequence in QRDR of both gyrA and parC; triangle=single gyrA mutation; open square=single gyrA mutation at codon D87; inverted triangle=gyrA double mutations at S83 and D87; solid square=gyrA double mutations at S83 and D87 and parC single mutation at S80; solid circle=S83F and D87N in GyrA and E84K in ParC; solid triangle=one mutation in each of gyrA and parC. 00:00=wild type for S83 and D87 in GyrA and S80 and E84 in ParC in the QBR; X0:00=change at S83 in GyrA but not in ParC; 0X:00= change at D87 in GyrA but not in ParC; XX:00=changes at S83 and D87 in GyrA and not in ParC; XX:X0=changes at S83 and D87 in GyrA and at S80 in ParC; XX:0X= changes at S83 and D87 in GyrA and at E84 in ParC; X0:X0=changes at S83 in GyrA and at S80 in ParC.
Conclusion: Mutations in the QRDR of gyrA play a major role in ciprofloxacin resistance in these isolates and the degree of resistance is related to the number of mutations. Double GyrA alterations alone can produce highly resistant ciprofloxacin phenotypes.

P1229 Prevalence of efflux pump activity and its role in ciprofloxacin resistance in clinical isolates of *Klebsiella pneumoniae*

S. Aathithan, G. French (London, UK)

Objectives: To determine the prevalence of efflux pump activity and its contribution to ciprofloxacin resistance in clinical isolates of *Klebsiella pneumoniae*.
Methods: Drug accumulation studies were performed on 26 ciprofloxacin susceptible and resistant isolates in early log-phase using [14^{C}] ciprofloxacin with and without the proton motive force dissipater carbonyl cyanide 3-chlorophenylhydrazone (CCCP). The total accumulation time studied was 20 minutes; CCCP was added at 10 minutes. The efflux index, a measure of efflux activity, was the ratio of the amount of drug accumulated at the 18th minute to the amount accumulated at the 4th minute. Membrane-associated reduced influx-mediated resistance (MARIM-R) was calculated by dividing the difference in drug accumulation at the 10th and the 4th minutes (in the absence of CCCP) by the amount of drug accumulated at the 4th minute. Values of >1.5 were significant.
Results: (Table). 92% of tested isolates were positive for efflux. The contribution of efflux to the removal of cell-bound ciprofloxacin ranged from 50% to 90% of total cell-associated drug. In some highly resistant isolates efflux pump activity extruded 90% of the drug. Efflux activity was present in all isolates with ciprofloxacin MICs >1 mg/L and contributed to reduced ciprofloxacin susceptibility in isolates that had no target site alteration. High-level activity usually occurred in isolates with high ciprofloxacin MICs, but these isolates usually had double GyrA alterations as well. None of the 26 isolates had MARIM-R.

Isolate #	CIP MIC mg/L	Efflux index	Efflux mediated reduction in drug accumulation (%)
1	0.016	1.8	46
2	0.032	2.1	44
3	0.064	5.4	81
4	0.25	1.7	49
5	0.5	1.3	6
6	0.5	5.1	79
7	0.125	1.3	30
8	1	5.4	82
9	1	6.8	86
10	2	4.4	79
11	4	2.3	58
12	4	4.1	76
13	4	4.5	69
14	4	5.2	77
15	8	2.0	55
16	8	7.6	87
17	128	6.8	85
18	128	9.0	89
19	>128	7.7	88
20	16	3.0	67
21	32	10.8	89
22	64	5.8	83
23	64	6.1	82
24	128	3.4	71
25	>128	3.5	72
26	>512	8.4	87

Conclusion: This study demonstrates that efflux activity is very common in *K. pneumoniae* and contributes to decreased ciprofloxacin susceptibility even in the absence of topoisomerase alterations. MARIM-R was not detected. Efflux activity may play a role in initial selection of isolates with reduced ciprofloxacin susceptibility, which then survive when ciprofloxacin is used. Surviving strains may then accumulate target site alterations and higher pump activity, leading to increasing ciprofloxacin resistance.

P1230 Mechanisms of fluoroquinolone resistance in *Salmonella enteritidis*

E. O' Regan, T. Quinn, S. Fanning (Dublin, IE)

Objectives: To determine the contribution of target gene mutations and efflux pump activity to nalidixic acid resistance in *S. enteritidis* field isolates (104 and 5408) and their in-vitro selected ciprofloxacin resistant mutants (104-cip and 5408-cip). The fitness cost associated with high-level fluoroquinolone resistance was also studied.
Methods: Disk diffusion and MIC testing were performed in the presence and absence of the efflux pump inhibitor Phe-Arg-beta-Naphthylamide (PABN). Ciprofloxacin accumulation was measured fluorometrically. Expression of the efflux transporter acrB, the global regulators soxS, marA, ramA and rob and the outer membrane porin ompF were measured by real-time RT-PCR. Invasiveness of ciprofloxacin resistant mutants was assessed in Caco-2 intestinal epithelial cells.
Results: High-level nalidixic acid resistance was associated with an Asp87Tyr mutation in gyrA. This resistance was partially reversed by PABN. Acquisition of high-level ciprofloxacin resistance resulted in additional mutations in gyrA, gyrB and parE. Ciprofloxacin-resistant mutants accumulated less ciprofloxacin than parent strains and demonstrated a multi-drug resistant phenotype attributable to enhanced efflux activity. Both mutants showed increased expression of acrB and the global regulator marA and a differential expression of soxS and ramA. Increased expression of acrB was not associated with mutations in its local regulator acrR. A mutation was found in the helix-turn-helix region of soxR in 104-cip that showed increased soxS expression. No mutations were found in any of the other global regulators investigated. Mutants formed smaller colonies and demonstrated slower growth rates than their parental strains. Mutants were significantly less invasive than the parents in Caco-2 cells. Electron microscopy revealed altered morphology of the mutants.
Conclusion: Both target mutations and efflux pump activity contribute to quinolone resistance in *S. enteritidis*. Increased expression of acrB may result from differential expression of global regulators. High-level ciprofloxacin resistance is associated with a fitness cost.

P1231 Virulence genotypes of *Escherichia coli* strains of human and avian origin in relation to ciprofloxacin resistance status

M. Cerquetti, C. Graziani, G. Parisi, F. Tomei, A. Fioravanti, M. Corrò, S. Morabito, I. Luzzi, A. Caprioli (Rome, Legnaro, IT)

Objectives: Previous studies have suggested that human fluoroquinolone resistant (FQr) *Escherichia coli* strains probably emerged as a consequence of fluoroquinolone use in poultry. This study aims to provide further insight on the possible avian origin of human FQr extra-intestinal pathogenic *E. coli* (ExPEC) strains.
Methods: The presence of 12 virulence factor (VF) genes (agg, eae, cldt, cnf, cvaC, ireA, iroN, iss, iucD, iutA, traT, tsh) commonly associated with human and/or avian ExPEC isolates was investigated by PCR in 125 *E. coli* isolates from extra-intestinal infections (61 susceptible and 64 ciprofloxacin resistant, respectively) and 113 isolates from chicken and turkeys (47 susceptible and 66 ciprofloxacin resistant, respectively). Genetic relatedness among 40 human and avian *E. coli* strains belonging to the traT-iucD-iutA virulence profile was assessed by PFGE.
Results: Irrespective of ciprofloxacin susceptibility, human isolates showed a significantly lower prevalence of cvaC, iroN, iss and tsh genes and a significantly higher prevalence of cnf compared to avian strains. Stratifying by ciprofloxacin susceptibility, susceptible human and avian isolates differed significantly for distribution of cnf, cvaC, iroN, iss, iucD, iutA and tsh genes, being all, except cnf, more frequent in avian isolates. Resistant human isolates differed from resistant avian isolates for distribution of 5 VF genes: iroN, iss, tsh (predominant in avian strains), iucD and iutA (predominant in human strains). Both human and avian FQr isolates harboured fewer VF genes than susceptible isolates. The two major VF profiles of the human isolates were traT-iucD-iutA and iucD-iutA, (65.6% of the resistant and 13.1% of the susceptible isolates). These two profiles were detected in a few resistant avian strains (traT-iucD-iutA, 9.1% and iucD-iutA, 3%). Conversely the two major profiles of avian strains (traT-cvaC-iucD-iroN-iss-tsh-iutA and traT-iroN-iss) did not occur among human isolates. By PFGE, an extensive genetic diversity was observed between the human and avian isolates belonging to the same traT-iucD-iutA profile.
Conclusion: Our results confirm previous data indicating strong differences in virulence genotype between ciprofloxacin susceptible and resistant human ExPEC strains. However, the resistant human isolates were distinct from both susceptible and resistant avian isolates and the results therefore do not support their avian origin.

P1232 Phylogenetic background of *Escherichia coli* resistant to quinolone and fluoroquinolone

A. Bas, E. Moreno-Pujol, M.N. Larrosa, A. Andreu, G. Prats on behalf of the Spanish Network for the Research in Infectious Diseases REIPI

Objective: To assess how resistance to quinolone (Q) and fluoroquinolone (FQ), and production of extended-spectrum β-lactamases (ESBLs) relates to the phylogenetic background of clinical *Escherichia coli* isolates.
Methods: A total of 337 *E. coli* strains, isolated from clinical samples were selected. The first 222 strains were collected consecutively after the susceptibility test, which allow selecting 120 strains Q and FQ susceptible (SS), 36 Q resistant and FQ susceptible (RS) and 66 Q and FQ resistant (RR). Further strains RS and RR were selected consecutively, till completed a total of 105 and 112 respectively. Resistance to nalidixic acid and ciprofloxacin was tested by disc diffusion method according to CLSI and presence of ESBLs by synergy test between clavulanic acid and third generation cephalosporins. Phylogenetic group was performed by a triplex PCR.
Results: The prevalence of Q resistance was 45.9% (102/222), FQ 29.7% (66/222), and 4.6% (11/222) produced ESBLs. Among the total of 337 isolates, the most prevalent phylogenetic group was B2 with 177 strains, followed by group D with 68, group A with 49 and B1 with 43. *E. coli* SS and RS showed a similar distribution among phylogenetic groups (66.7% and 60.9% in group B2, 15% and 20% in D, 11.7% and 8.6% in A and 6.7% and 10.5% in B1). However RR strains exhibited a shift to non-B2 groups: 23.2% derived from group A, 21.4% from B1, 25.9% from D and 29.5% from B2, (RR vs. RS $P<0.01$ in groups A, B1, B2; RR vs. SS $P<0.01$ in groups B1, B2, D). Of the 337 *E. coli* studied, 20 produced ESBLs: 1 strain SS, 6 RS and 13 RR ($P<0.05$ in SS vs. RS and SS vs. RR). ESBLs producers exhibited a similar distribution among phylogroups A, B1 and D (8.2, 11.6 and 10.2%); whereas were quite less prevalent in pathogenic group B2 (2.3%; $P<0.05$).
Conclusion: *E. coli* resistant to Q mainly derived from phylogenetic group B2, whereas isolates resistant to both Q and FQ exhibited shifts towards groups A, B1 and/or D. This fact led us to suspect that these two subgroups represent distinct populations, RS isolates could have derived predominantly from susceptible *E. coli* group B2 (possibly within a human host), whereas RR isolates from susceptible *E. coli* group A isolates (possibly within an animal host), both in the context of drug exposure. The depletion for phylogenetic group B2 among ESBLs producers suggest a similar phenomenon.

P1233 **Genetic relatedness between ciprofloxacin-resistant *Salmonella* Kentucky isolated from humans and poultry meat**

B. Bouchrif, M. Timinouni, K. Zerouali, N. Cohen, M. Ennaji, J.D. Perrier-Gros-Claude, F.X. Weill (Casablanca, Mohammedia, MA; Paris, FR)

Objectives: To compare *Salmonella enterica* serotype Kentucky strains (*Salmonella* Kentucky) resistant to ciprofloxacin isolated in France from travellers returning from Morocco with those from raw poultry meat produced in Morocco.

Methods: *Salmonella* Kentucky strains from poultry meat (n = 3) have been identified between December 2006 and June 2007 during a food safety survey conducted since 2004 in Pasteur Institute from Morocco. Strains from human origin (n = 3) have been isolated from travelers returning from Morocco (2006: n = 3; 2007, n = 3), and from a patient hospitalised in the Ibn Rochd Hospital (Casablanca) in 2006. Nalidix acid and ciprofloxacin MICs were performed by E-Test. To identify the mechanisms of resistance to ciprofloxacin, the quinolone-resistance determining regions of gyrA and parC were sequenced and the presence of plasmid-mediated quinolone resistance genes (qnrA-B-S, aac(6′)-Ib-cr) were tested for all isolates. All isolates were genotyped by pulsed-field gel electrophoresis (PFGE) with XbaI restriction following PulseNet's running conditions.

Results: Among the 13 strains, 9 (poultry meat, n = 3; patients, n = 3) were resistant to nalidixic acid and to ciprofloxacin (MIC > 16 mg/l, >1 mg/l respectively) and have the same amino-acid substitutions within gyrA and parC (gyrA: Ser83-Phe, Asp87-Asn; parC: Ser80-Ile). Within parC, an additional substitution (Thr57-Ser) was observed. This substitution, however, did not appear to be associated with quinolone resistance because it was also identified in nalidixic acid-susceptible isolates. All strains were negative for plasmid mediated quinolone resistance genes. Among quinolone-resistant isolates, 2 PFGE patterns were displayed: the first one (P1) was observed in all poultry isolates and 4 human isolates; the second one (1 traveler isolate) shared 80% identity with P1. For quinolone-susceptible strains, 3 PFGE patterns were displayed and shared less than 50% identity with previous PFGE profiles.

Conclusions: this study showed clearly the close genetic relatedness among ciprofloxacin-resistant *Salmonella* Kentucky isolates and identified poultry meat as a probable source for human contamination. Moreover, it can be assumed that an unique ciprofloxacin-resistant *Salmonella* Kentucky has spread all over different poultry flocks in the Casablanca's region.

P1234 **Epidemiology of elevated fluoroquinolone MICs of *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* from the GLOBAL Study (1999–2005)**

N. Brown, D. Draghi, D. Sahm, C. Pillar (Herndon, US)

Objective: Isolates (ISO) were collected during 1999, 2002, 2003, and 2005 as part of the GLOBAL study, during which 360 *S. pneumoniae* (SP) showed levofloxacin (LFX) MICs ⩾2 mg/L by broth microdilution. Serotyping profiles of these SP were determined in this study. Previous experience has shown that in studies where LFX resistance rates were in excess of 1% that it was often the result of an outbreak of clonal ISO. To address the relatedness of SP ISO from 2005 with elevated LFX MICs, pulsed-field gel electrophoresis (PFGE) was performed and related to QRDR profile and serotype (ST). In addition, 8 ISO of H. influenza (HI) and *M. catarrhalis* (MC) with elevated LFX MICs (⩾0.05 mg/L) were subjected to PFGE analysis to determine relatedness, if any.

Methods: ISO were centrally tested by broth microdilution (CLSI; M7-A7) and interpreted according to CLSI M100-S16 and M45-P (MC). 84 SP with MICs ⩾2 mg/L were STed using standard methodology. ISO of SP, HI, and MC from 2005 with elevated LFX MICs underwent PFGE. ISO with ⩾90% similarity in PFGE pattern were considered related. SP were further characterised by sequencing the quinolone resistance determining regions (QRDRs) of gyrA, gyrB, parC, and parE.

Results: Among the 360 SP with elevated LFX MICs from 1999–2005, 44 STs were identified and STs 23F, 14, and 19F were the most common (>10% each). Among the 2005 SP ISO (N=86), STs 8, 19F, and 23F were detected at >10%. Of these, there were 5 genetically related groups detected by PFGE (1 centre in Spain (ES) [n = 3], 2 separate centres in ES [n = 34], 1 centre in Hong Kong (HK) [n = 3], a separate centre in HK [n = 3], and 1 centre in Germany (DE) [n = 3]). Similar STs and QRDR profiles were observed within each group. The remaining SP ISO showed little genetic similarity with a wide distribution of STs. Little genetic relatedness was observed among ISO of HI and MC with elevated LFX MICs.

Conclusion: Among the SP from 2005 with elevated MICs to LFX, 5 clusters of genetically related ISO were detected suggesting outbreaks of certain lineages of this phenotype within centres in ES, DE, and HK. The remaining SP ISO were of variable ST, PFGE patterns and QRDR profiles. Few HI and MC ISO with elevated LFX MICs were detected in 2005, and no genetic relatedness was apparent among these ISO. These results illustrate the importance of utilising both surveillance and molecular epidemiological studies for monitoring the emergence and spread of resistance.

P1235 **Molecular analysis of fluoroquinolone resistance in *Streptococcus pneumoniae* in Turkey**

O. Koseoglu Eser, K.P. Klugman, L. McGee and the Turkish Pneumococcal Study Group

Objectives: Fluoroquinolones(FQs) are recommended drugs for the treatment of *Streptococcus pneumoniae* infection which increase the risk for the development of resistance. FQ resistance occurs primarily by mutations in quinolone resistance determining regions(QRDRs) of parC, gyrA, parE and/or gyrB genes. The aim of this study was to evaluate fluoroquinolone-resistant *S. pneumoniae* in multicentre isolates from Turkey to investigate the mechanisms of resistance.

Methods: A total of 288 out of 297 study isolates with MIC⩾1g/L for Levofloxacin(LEV) were amplified by PCR for the QRDRs of gyrA, parC and parE. Restriction fragment length polymorphism (RFLP) by HinfI, MboII, LweI digestions of PCR products was carried out to identify mutations known to confer FQ resistance. Isolates with mutations by PCR-RFLP analyses were confirmed by DNA sequence analysis. MICs were also determined for penicillin(PEN), ceftriaxone(CRO), erythromycin(EM) and clindamycin(CD) by broth microdilution using CLSI methods. Serotyping was performed using sequential multiplex-PCR and quellung reaction with capsular antisera for *S. pneumoniae*.

Results: Twenty-four(8.1%)*S. pneumoniae* strains were levofloxacin nonsusceptible(MIC ⩾4g/L) and antimicrobial susceptibilities of these isolates are presented in Table 1. Fifteen different serotypes were recognised. Eleven strains had mutations in QRDR of parC (K137N(n = 3) and S79Y, D83N(n = 3)). Eighteen isolates had parE mutations (I460V(n = 38) and D435N(n = 3)). All isolates with MICs of 4g/L contained no mutations in gyrA, parC or parE that are known to confer resistance to FQs. Although there were eight isolates with MIC ⩾8 g/L, only three of levofloxacin-resistant isolates analysed possessed a gyrA mutation (S81F). Two of these strains had additional mutations in parC(S79Y,D83N) and one strain had the D435N mutation in parE known to confer resistance. They all had different serotypes belonging to 34, 23F and 6B.

Table 1. Antimicrobial susceptibilities of 24 FQ-resistant isolates

	MIC_{50}	MIC_{90}	Range	I (%)	R (%)
LEV	4	>8	4–>8	16 (66.7)	8 (33.3)
PEN	⩽0.06	>2	⩽0.06–>2	6 (25.0)	5 (20.8)
CRO	⩽0.25	2	⩽0.25–2	5 (20.8)	–
EM	⩽0.25	>8	⩽0.25–>8	–	7 (29.2)
CD	⩽0.25	>8	⩽0.25–>8	–	6 (25.0)

Conclusion: FQ nonsusceptibility was observed in 8.1% of isolates in this study. Mutations known to confer resistance to FQs were not observed in strains with MICs of 4g/L. Three of eight strains showing higher levels of resistance contained mutations in the QRDRs of gyrA, parC and parE, however 5 strains were either wild-type or contained mutations which do not confer resistance. This data suggests that perhaps other mechanisms of resistance to the FQs are present in these strains such as efflux or mutations outside the QRDR region.

P1236 Interactions between serotype and mutations in quinolone-resistance determining regions of *Streptococcus pneumoniae*

R. Melano, A. McGeer, S. Drews, S. Pong-Porter, J. Gubbay, C. Seah, R. Higgins, G. Tyrrell, K. Green, D.E. Low on behalf of the Canadian Bacterial Surveillance Network

Background: Mutations in QRDR regions are the primary cause of fluoroquinolone resistance (FQR) in *S. pneumoniae* (SPN). It is not known whether the distribution of mutations and/or the association of QRDR with increasing MIC is similar in different SPN serotypes (STs).
Methods: The Canadian Bacterial Surveillance Network (CBSN) has been monitoring trends in antimicrobial resistance in SPN in Canada. From 1995–2006, 27,951 isolates from across Canada have been collected. Serotyping and sequencing of the gyrA and parC regions was performed for all FQR isolates FQ (N=451), and a sample of others (N=3438).
Results: The most common parC mutations were: K137N (N=870), S79F (293), S79Y (106), D83N (36), D83Y (17), D83G (9), S52G (6), N91D (6), R95C (5), Y129S (5), D78N (4), S79A (2), A115P (2). 14 other mutations were identified once. S79F, S79Y, D83N/Y/G, D78N/A, and A115P were associated with increased MICs to FQ; other mutations were not. K137N was present in <5% of isolates of SGs 3, 4, 10, 11, 15, 18, 20, 22, 33, 35, 38, >85% of isolates of SGs 12 and 9, and an intermediate percentage of other SGs. Among FQR, S79Y is significantly more common in isolates of ST 22F, 6A and 6B, and mutations at position 83 are more common in ST 9N and 9V ($P < 0.01$). Of isolates with parC mutations, those of ST 12F had significantly lower MICs to all FQ than those of other STs. 27% of FQS SPN with a parC mutation at position 79 were ST 12F, compared to 3% of FQR isolates. The most common gyrA mutations were S81F (N=179), S81Y (33), E85K (33), S114G (14), E85G (4). 12 other mutations were identified once. Only mutations at position 81 and 85 were associated with increased FQ MICs. The prevalence of gyrA mutations in the presence of parC mutations varied significantly with ST; eg. 10/12 (83%) 19A and 32/40 (80%) 19F strains with a parC mutation also had a gyrA mutation, compared to 9/24 (38%) ST 3 and 6/17 (35%) ST 12F ($P < 0.001$). When isolates were categorised by whether or not their serotypes were included in 7- or 23-valent pneumococcal vaccines, there were no significant differences in the prevalence of parC mutations. Isolates of STs in the 23-valent vaccine with a parC mutation were somewhat less likely to have a gyrA mutation than other isolates (66% vs 55%, $P = 0.07$).
Conclusion: Mutations in QRDR determining regions occur with differing frequencies in isolates of different ST. Changing ST distributions associated with pneumococcal vaccination programs may have an impact on FQR rates.

P1237 Identification of SmrA, a novel efflux pump involved in fluoroquinolone resistance in *Streptococcus suis*

J.A. Escudero, A. San Millán, L. Hidalgo, B. Gutierrez, S. Nieto, L. Domínguez, A.G. De la Campa, B. González-Zorn (Madrid, ES)

Objectives: *Streptococcus suis* is a world-wide distributed pathogen with increasing prevalence in humans. It has recently been reported as the cause of high mortality outbreaks in Southeast Asia among the population in close contact with infected pigs or contaminated food.
During the last years rising fluoroquinolone resistance among Spanish isolates collected in our laboratory has been observed. We have recently described the influence in this phenotype of mutations in gyrA and parC, the genes encoding the drug's targets (Escudero et al. AAC 2007 51:777–82). Interestingly, the MIC of some strains was reduced in presence of reserpine pointing to the coexistance of a drug efflux phenomenon.
Methods: Strains identification was PCR based. MICs were carried out following CLSI guidelines. PFGE was performed using ApaI endonuclease. Sequencing of PCR products was performed by Secugen S.L. 4Peaks, CLC workbench, DNA Strider and Phyre (www.sbg.bio.ic.ac.uk/phyre/) were used for sequence analysis and protein modeling.
Results: *S. suis* available genomes were scanned for the presence of putative efflux pumps. A gene encoding a 401 aminoacid protein sharing 58% homology with PmrA, an efflux pump related to fluoroquinolone resistance in *S. pneumoniae*, was identified and named SmrA (*suis* multidrug resistance). Protein modeling of SmrA, revealed 12 transmembrane segments and elicited to assign this putative pump to the Major Facilitator Superfamily (MFS). Complete nucleotide sequence of smrA including its promoter region was determined from five fluoroquinolone susceptible clinical isolates, three high level resistant and two intermediate level resistant strains. PFGE of all strains revealed no genetic link between all isolates. Sequencing of these regions revealed the presence of mutations leading to a critical aminoacid substitution in position 107 (V/T107A) in all five resistant clinical isolates. Furthermore the three high level resistant isolates bore mutations in the putative −10 box, indicating that, as for other MFS members, protein structure together with expression levels are involved in SmrA mediated fluoroquinolone resistance in *S. suis*.
Conclusion: SmrA is a novel member of the Major Facilitator Superfamily and plays a role in fluoroquinolone resistance in clinical *S. suis* isolates. Acquisition of this efflux phenotype seems to be a stepwise phenomenon involving mutations in the promoter region as well as in the structural gene of SmrA.

P1238 Epidemiological analysis of fluoroquinolone-resistant group B streptococci

A. Yoshida, Y. Okamoto, T. Tarukawa, S. Koike, H. Wakimoto, H. Yoshida, A. Hishinuma, K. Okuzumi (Mibu, Tochigi, Nagakute, Aichi, JP)

Objectives: We reported increasing number of fluoroquinolones (FQ)-resistant group B streptococci (*S. agalactiae*; GBS) in Japan since 2000. FQ-resistant GBS was isolated from neonates and their mothers and elderly patients with underlying urogenital diseases or hematological malignancies under long-term administration of FQ. Analysis of the mechanism of FQ-resistance in addition to epidemiological studies was performed to reveal whether FQ-resistant GBS was genetically related.
Methods: Clinical and epidemiological data were obtained from patients with GBS isolated in our 1300-bed tertiary hospital between October 2005 and January 2007. FQ-resistance was judged with MIC in case of $>8\,\mu g/ml$ for levofloxacin. Serotypes of GBS were determined by antisera (Denka Seiken, Tokyo). The nucleotide sequences of the quinolone resistance-determining region (QRDR) including of gyrA gene and parC gene were determined. Pulsed-field gel electrophoresis (PEGE) analysis was performed on GBS strains.
Results: From 84 patients, 91 GBS were isolated from 49 genitourinary, 35 respiratory, 4 tissue, 2 blood, one peritoneal specimens. FQ-resistant GBS were 21 from 17 (20%) patients. All FQ-resistant GBS except one (94%) was serotype Ib, whereas FQ-sensitive GBS belonged to various serotypes (VII, V, Ia, Ib, III, II, VIII, and NT). FQ-resistant GBS had the same triple point mutations within QRDR; In gyrA gene, Ser-81 was changed to Leu (TCA-TTA) in 11/11 strains, and in parC gene Ser-79 was changed to Phe (TCC-TTC) and Ile-81 had a silent mutation (ATC-ATT) in 10/10 strains. PFGE on 16 FQ-resistant GBS revealed 4 major groups with high relatedness, although FQ-sensitive GBS showed slightly related PFGE patterns.
Conclusion: Most of all FQ-resistant GBS was serotype Ib and shared identical mutations in the QRDR and high related PFGE patterns. These findings suggest that the closely related FQ-resistant GBS had been possibly emerged and disseminated in the community in recent years, as receiving the antibiotic pressures by quinolone administration.

P1239 **Molecular characterisation of quinolone-resistance in erythromycin-resistant *Streptococcus agalactiae* clinical isolates**

M.E. Llaneza, C. Seral, M. Pardos, E. Durán, F.J. Castillo, M.C. Rubio, R. Gómez-Lus (Zaragoza, ES)

Objectives: *Streptococcus agalactiae* (GBS) remains susceptible to penicillin; nevertheless, an increase in the resistance to other antimicrobial families, such as macrolides and more rarely fluoroquinolones, has been described. The purpose of the study was to surveillance the fluoroquinolone resistance in GBS isolated from blood cultures, in erythromycin-resistant GBS isolated from vaginal colonisation and characterise the molecular mechanisms of resistance implicated and their genetic similarity.
Methods: Antimicrobial susceptibility (according to CLSI guidelines) of 153 erythromycin-resistant GBS from vaginal colonisation (2002–2004) and 28 GBS from blood cultures (1994–2004) were recorded by our Clinical Laboratory (Hospital Lozano Blesa, Zaragoza, Spain). Levofloxacin and ciprofloxacin resistance in GBS was identified by disk diffusion and broth microdilution methodology in all the isolates. Therefore, we determined the nucleotide sequences and deduced amino acid sequences of gyrA and parC genes including QRDRs in 5 isolates with low-level susceptibility to levofloxacin. These sequences were compared with those of susceptible strains. Pulsed-field gel electrophoresis (PFGE) analysis was performed on the 5 GBS isolates following Sma1 digestion.
Results: Five low-level fluoroquinolone-resistant GBS strains were detected (MICs range were 0.5–2 mg/l) but no high-level fluoroquinolone-resistant GBS (MICs >8 mg/l) were found in the GBS isolates. Of these, in 3 isolates no mutations in the QRDR of parC were found, in a blood isolate collected from a patient previously treated with norfloxacin the sequence analysis of the parC gene showed a base pair chain TCT/CCT at position 238 that resulted in an aminoacid substitution Ser80Pro and in a vaginal isolate three parC silent mutations were found and their implications in quinolone resistance remains unclear. No mutations in the QRDRs of gyrA were detected. The PFGE pattern study did not suggest genetic relation of these five isolates.
Conclusion: Low-level fluoroquinolone-resistant GBS were recovered from 5 patients and we found that one contained an aminoacid substitution in the topoisomerase IV gene (Ser80Pro). This mutation was described previously only in *Streptococcus pyogenes*. It seems that parC is the primary target of the quinolones in *S. agalactiae*. These findings emphasise the importance of monitoring antibiotic susceptibility to quinolones antibiotics.

PK/PD: clinical studies

P1240 **Pharmacokinetics of azithromycin in plasma and sinus tissue after administration of extended release and immediate release formulations in chronic rhinosinusitis patients**

A.F. Fang, J.N. Palmer, A.G. Chiu, J.L. Blumer, P.H. Crownover, M.D. Campbell, B.D. Damle (New York, Philadelphia, Cleveland, US)

Objectives: High drug levels at an infection site are desirable for optimal activity. The aim of this study was to determine if a single dose of azithromycin (AZ)-extended release (ER) (2 g) achieves higher AZ levels in sinus tissue compared to AZ-immediate release (IR) (500 mg daily for maximum of 3 days).
Methods: This was a randomised open-label multi-centre study. Seventy-one chronic rhinosinusitis patients received either a single dose of 2-g AZ-ER or AZ-IR 500 mg once daily dose for 1–3 days. Sinus tissue and plasma samples were collected at the time of endoscopic surgery, which was 2, 4, 6, 8, 12, 24, 48, 72, 96, 120, 144 and 168 hr after the first AZ dose, 4 subjects per time point. AZ levels were analysed by LC/MS/MS method and averaged at each time point. The resultant composite profile was used for Pharmacokinetics (PK) analyses by a non-compartmental method.
Results: Sixty-eight patients completed the study. The patients aged 19–81, with majority being white (90%) and males (59%). 53 subjects were evaluable for PK analysis.
After the administration of both formulations, AZ was absorbed and distributed quickly in systemic circulation. Sinus tissue concentrations were measurable at 168 hr from both formulations. PK parameters are shown in the table.

Matrix	Parameter	AZ-ER (n = 24)	AZ-IR (n = 29)	ER/IR Ratio
Plasma	C_{max} (ng/mL)	364	112	3.3
	AUC_{24} (ng·h/mL)	4865	933	5.2
	AUC_{168} (ng·h/mL)	10994	N/A	
Sinus tissue	C_{max} (ng/mg)	12.2	1.44	8.5
	AUC_{24} (ng·h/mg)	137	19.7	7.0
	AUC_{168} (ng·h/mg)	684	N/A	

N/A = not applicable.

Comparison between formulations: Within the first 24 hr, AZ exposure from ER was 5.2 and 7.0 fold higher than IR in plasma and sinus tissue respectively. This is consistent with the dose from ER being 4 times higher than IR.
Comparison between matrices: For ER formulation, AUC_{24} and AUC_{168} in sinus tissue were 28.2 and 62.2-fold higher than in plasma, which indicates that once AZ enters the sinus tissue, it remains for a prolonged duration. For IR formulation, AUC_{24} in sinus tissue was 21.1-fold higher than AUC_{24} in plasma, which is similar to the ER penetration ratio.
Conclusions: AZ demonstrated good penetration into sinus tissue regardless of formulation. However, dosing with AZ-ER (2 g) resulted in an increased exposure compared to the first dose of 500 mg IR within the first 24 hr after start of therapy.

P1241 **Penetration of voriconazole into human tissue**

S. Weiler, R. Bellmann-Weiler, M. Joannidis, R. Bellmann (Innsbruck, AT)

Objectives: Voriconazole (VRC) is a second-generation triazole with a broad antimycotic spectrum. VRC exhibits a good penetration into body fluids, such as cerebrospinal fluid, epithelial lining fluid and pleural effusion. Data on VRC distribution into human tissue after administration of VRC have been sparse so far. VRC tissue levels were determined in tissue samples obtained during routine autopsy from patients who have died during treatment with VRC.
Methods: VRC levels were measured in various samples derived from different tissues (kidneys, liver, heart, spleen, lung, brain) of 2 patients, who had been on treatment with VRC. Patient 1 had received a single dose of 200 mg, patient 2 had obtained 200 mg/day for 10 days. The intervals between the last administration and death were 36 and 12 hours, respectively. Both patients had been on vasopressor therapy and mechanical ventilation. Antimycotic therapy had been initiated for suspected or proven invasive fungal infections. VRC tissue levels were assessed by extraction of homogenised tissue samples, purification by solid phase extraction and measurement of VRC by high performance liquid chromatography.
Results: In VRC treated patients, highest VRC concentrations (mean ± standard deviation) have been found in the kidneys (patient 1: 1.97±0.41 μg/mL, patient 2: 6.89±0.06 μg/mL) and liver (patient 1: 2.14±0.40 μg/mL, patient 2: 4.21±0.77 μg/mL). Tissue levels of VRC in patient 2 exceeded those achieved in patient 1 in all samples. In different areas of brain tissue VRC was below the limit of detection (<0.25 μg/mL) in patient 1 and achieved levels of 3.34±0.18 μg/mL in patient 2. The levels were comparable in cortex, hippocampus, nucleus caudatus, medulla oblongata and cerebellum. VRC concentrations amounted 1.31±0.03 μg/mL and 2.95±0.05 μg/mL in samples of the spleen of patient 1 and 2, respectively. In the heart samples of

patient 1 VRC was undetectable, but reached a mean concentration of 2.44±0.25 μg/mL in patient 2. In all lung samples VRC was measurable and reached mean levels of 1.30±0.63 μg/mL (patient 1: 0.74±0.02 μg/mL, patient 2: 1.87±0.27 μg/mL).
Conclusion: VRC appears to penetrate rapidly into human tissues. VRC accumulates in the liver and the kidneys. Its penetration into brain and heart is probably slower.

P1242 Pharmacodynamics of vancomycin against MRSA: implications of bacterial inoculum for the clinical breakpoint

A. MacGowan, K. Bowker, C. Tobin, A. Lovering, A. Thomson, A. Noel (Bristol, UK)

Background: Vancomycin (V) is gold standard therapy for MRSA infection, yet despite wide clinical usage the clinical breakpoint to define susceptible *S. aureus* remains controversial (CLSI $S \leqslant 2$ mg/L; EUCAST $S \leqslant 4$ mg/L). We used an in vitro pharmacokinetic (PK) model to define AUC/MIC targets for various V antibacterial effects (ABE) against MRSA and used these in Monte Carlo simulations using patient PK data to define various clinical target attainment rates (TAR).
Methods: An in vitro PK model was used to perform a dose ranging study with two representative UKEMRSA 15 or 16 strains at inoculum of 10^6 or 10^8 CFU/ml. The AUC/MIC range was 0–2500. Total V AUC/MIC for 24 h static, 1, 2, 3 or 4 log drop in bacterial count were established for each inoculum using a Sigmoid Emax model. Patient V AUC 24 (mg/L.h) was derived from a population PK model developed for V. Monte Carlo simulations were used to define TAR using patient AUC values and AUC/MIC targets from the PK model.
Results: At an inoculum of 10^6 CFU/mL the total drug AUC/MIC required at 24 h for a static effect was 34: 1 log drop 66; 2 log drop 254; 3 log drop 303 and 4 log drop >2500. At an inoculum of 10^8 CFU/ml the AUC/MIC for a 1 log drop at 24 h was 426, 2 log drop 588 and 3 log drop >2500. Patient AUC 24 (mg/L.h) was mean 472±221 (min 155, max 1306, n = 50 subjects). A total V AUC/MIC target associated with 0–1 log drop (initial inoculum 10^6 CFU/ml) resulted in a TAR of >90% at an MIC 4 mg/L. The AUC/MIC targets associated with a similar ABE at 10^8 CFU/mL resulted in a TAR of >80% at MICs of 0.5 mg/L.
Conclusion: MRSA inoculum has a significant effect on TAR for V. At an inoculum of 10^6 CFU/mL a clinical breakpoint for V of 4 mg/L is justified; at 10^8 CFU/ml inoculum a breakpoint of 0.5 mg/L is more appropriate.

P1243 Identification of mutations in HERG and KCNE2 genes associated with arrhythmia in patients treated with macrolides

M. Pannacci, A. Caronno, V. Lucini, S. Grosso, F. Scaglione (Milan, IT)

Several new antibiotics have been whitedrawn from the market because of rare or exceptional but life-threatening adverse effects. Macrolides and fluoroquinoles are widely prescribed for treatment of infections and are traditionally known to cause Q-T interval prolongation and are at risk to induce Torsade de Pointes (TdP) that represent one of the most dangerous effects with these drugs. Recently, erithromycin was found to induce TdP, with relative high frequency, even if administered by oral route. A recent trial conclude that short term clarithromycin in patients with stable coronary heart disease may significantly cause higher cardiovascular mortality. Genes who are involved in congenital long-QT (cLQT) syndromes may also be involved in acquired LQT (aLQT), induced by drugs. Studies of genetic risk factors have been performed in the United States and Western Europe, suggesting that genetic mutations in genes codifing for potassium channels and involved in cLQT may be common in patients with drug-induced arrhythmias. Some studies have shown prolongation of the QT interval and blockade of the potassium channel encoded by HERG gene. HERG forms voltage-gated K channels that are associated with Mink-related peptide 1 (MIRP1), encoded by KCNE2 gene. Mutations in HERG and KCNE2 genes may be correlated with susceptibility to drug-induced arrhythmia.
Methods: Venous blood samples from 25 unrelated patients and of 40 unrelated subjects, as control, were taken after informed consent. Genomic DNA was isolated using standard procedures and PCR was carried out using specific primers that cover the complete coding regions and intron-exon boundaries. Single-strand conformation polymorphism (SSCP) analysis was performed to identify mutations in the coding regions and anomalous PCR products were sequenced.
Results: Screening for mutations in HERG and KCNE2 genes with SSCP, identified an abnormal SSCP conformer in the KCNE2 gene from DNA of one patient during treatment with erythromycin and another in HERG gene from one patient treated with clarithromycin. Sequenced analysis revealed a mutation, leading to 1-bp deletion (delA, 360) and (C1039T) respectively.
Conclusion: Individual case reports have shown that patients with macrolides-induced arrhythmia may carry sporadic mutations in HERG and KCNE2 genes. These results should be validated by further studies in a large population in order to evaluate the statistical association with polymorphisms and drug-induced arrhythmia.

P1244 Pharmacokinetic characterisation of ertapenem following subcutaneous administration in acutely ill patients

D. Frasca, S. Marchand, O. Mimoz, W. Couet (Poitiers, FR)

Objective: To compare the pharmacokinetic and pharmacodynamic parameters of sequential intravenous and subcutaneous ertapenem in the plasma of surgical intensive care unit patients.
Methods: Six patients, all males, between 19 and 82 years old, with suspected hospital-acquired infection due to an ertapenem-susceptible bacteria gave their informed consent to participate. Patients with abnormal renal function (estimated creatinine clearance <30 ml/min/1.73 m^2), cardiac failure, receiving vasopressor agents or having a body mass index >30 kg/m^2 were excluded. Ertapenem 1g was administered first as a 30min intravenous infusion once a day. At steady-state, between the fourth and the seventh day after the antibiotic administration started, the pharmacokinetic study for the intravenous route was performed (13 blood samples). The day thereafter, the pharmacokinetic study for the subcutaneous route was performed after administration of ertapenem 1g as a 30 min subcutaneous infusion (12 blood samples). Blood samples were centrifuged for 10min at 4°C to separate the plasma, and ertapenem concentrations were measured using a validated LC-MS/MS assay. A 2 open-compartmental model with zero order administration was used for pharmacokinetic calculations and derived parameters were used for simulations.

Table Ia: Mean±SD pharmacokinetic parameters

	AUC (μg/mL×h)	Cmax (μg/mL)	Tmax (h)	MAT (h) au choix	$t\frac{1}{2}$ (h)
IV infusion	317±158	115±28	0.5	0.25	3.9±1.2
Sub-cut infusion	313±184	43±29*	2.7±1.1*	3.4±2.7	5.4±1.4

*$p < 0.01$.

Table Ib: Simulated plasma concentrations time over MIC in percentage according to various MIC values

	MIC = 1 μg/mL	MIC = 2 μg/mL	MIC = 4 μg/mL	MIC = 8 μg/mL
IV infusion	87±17%	74±19%	58±19%	40±16%
Sub-cut infusion	96±8%	91±13%	71±14%	47±14%

Results: All treatments were well tolerated. Mean±SD pharmacokinetic parameters are listed in Table Ia. The major observation was that ertapenem concentrations versus time profiles were shifted to the right after subcutaneous administration and time to peak (Tmax) was considerably delayed with peak concentrations (Cmax) reduced to about 1/3. However area under the curves (AUC) were similar for both administration route with a ratio of AUCsubcut/ AUCIV = 0.99±18)

and simulations indicate that time over MIC had a tendency to be longer after subcutaneous administration independently on the selected MIC value (Table Ib).
Conclusion: Subcutaneous administration seems to be an interesting alternative to intravenous infusion in acutely ill patients.

P1245 Variability in cefazolin concentrations in amniotic fluid: the relevance of gestational age

K. Allegaert, T. van Mieghem, R. Verbesselt, J. de Hoon, G. Naulaers, J. Deprest, R. Devlieger (Leuven, BE)

Objectives: Cefazolin is frequently administered for prophylaxis during foetal surgical interventions, but data on amniotic drug disposition and the determinants of its variability during pregnancy are still limited. We therefore wanted to document cefazolin disposition in the amniotic fluid and the determinants of its variability.
Methods: A first dose of cefazolin (2 g iv) was administered (time interval 30 min) one or two hours before foetal surgical intervention. Amniotic fluid sampling was performed when puncture of the amniotic cavity and subsequent sampling of amniotic fluid was part of the routine clinical care without addition burden for either mother or foetus. Time of sampling (min) was registered and gestational age (GA, weeks) at surgery was recorded. Cefazolin concentrations were determined based on High Performance Liquid Chromatography methodology (1). Data were reported by median and range, spearman rank correlation and multiple regression were used to assess the impact of time of sampling and GA at surgery on the variaibility in cefazolin concentrations observed in the amniotic fluid.
Results: 57 amniotic fluid samples were collected during foetal surgical interventions. The median cefazolin amniotic concentration was 0.82 (range 0.06–3.73) mg/L. Median GA was 26 (range 17–34) weeks, median time at collection was 100 (range 20–370) minutes. There is a significant increase in cefazolin concentration with time (r = 0.41, 95% CI 0.17–0.6) and with GA (r = 0.58, 95% CI 0.37–0.73). In a multiple regression model, both variables remained independent determinants of the amniotic cefazolin concentration (r adj = 0.35)
Conclusions: There is important variability in cefazolin concentrations in amniotic fluid during pregnancy. In addition to time of sampling after intravenous maternal administration, gestational age also contributes to this variability, suggesting the impact of maturational aspects (protein binding, placental transfer, foetal renal elimination) on cefazolin disposition during pregnancy.

P1246 Cerebrospinal fluid compartmental pharmacokinetics of amikacin in neonates

K. Allegaert, I. Scheers, E. Adams, G. Brajanoski, V. Cossey, B.J. Anderson (Leuven, Louvain, BE; Auckland, NZ)

Objectives: To describe and investigate covariate effects (leukocytosis, glycorrhachia, protein concentration) on cerebrospinal fluid (CSF) pharmacokinetics of amikacin in neonates.
Methods: CSF samples were prospectively collected from neonates in whom amikacin had been initiated before a diagnostic lumbar puncture was performed. CSF analysis (amikacin concentration, white blood count, glucose content, protein concentration) and amikacin therapeutic drug monitoring results (peak and trough concentrations) in plasma were recorded. A two compartment (central and CSF) linear disposition model was used to estimate population pharmacokinetics. The half-time (Teq) for equilibration between plasma and CSF compartments was used as a measure of blood brain barrier permeability.
Results: Based on 44 CSF amikacin concentrations and 83 plasma samples available from 43 neonates, data analysis revealed two distinct groups of neonates: those with a very short Teq (0.155 SD 0.024 h) and those with a long Teq (67.9 SD 22.5 h). A white cell count above 21 cells per mm3 in the CSF was associated with a low Teq while no relationship between Teq and CSF glucose or protein could be established.
Conclusions: There is important between individual variability in Teq following amikacin administration in neonates that is associated with CSF WBC. The impact of CSF WBC on amikacin Teq is of potential relevance for both effectiveness and ototoxicity of this drug in neonates.

P1247 Contributors to between-individual variability of amikacin clearance in neonates

K. Allegaert, K. De smet, I. Scheers, E. Adams, V. Cossey, B.J. Anderson (Leuven, Louvain, BE; Auckland, NZ)

Objectives: We recently documented that size (49%), renal function (14%) and postmenstrual age (PMA 18%) are the major contributors to vancomycin clearance variability in neonates, leaving only 18% of variability unexplained. A variable slope sigmoidal model fitted best to describe the relationship between vancomycin clearance and PMA (1). A similar exercise in a large dataset of amikacin concentrations in neonates was undertaken to test applicability of the current model to others drugs, like amikacin, cleared by renal elimination.
Methods: Population pharmacokinetics were estimated (NONMEM) in a cohort of 715 neonates (PMA 24–43 weeks; weight 0.385–4.780 kg) and were based on 1 862 amikacin time-concentration points. Covariate analysis included weight, PMA, postnatal age (PNA), creatinaemia, use of inotropes or ibuprofen, positive blood culture and respiratory support. A one-compartment linear disposition model with zero order input and first order elimination was used.
Results: The population estimate for volume of distribution (V) was 32.1 L/70kg and 1.21 L/h/70kg for clearance (CL). CL increased from 0.84 L/h/70kg at 28 weeks PMA to 1.23 and 1.56 L/h/70kg by 34 and 40 weeks PMA. Overall 92% of the variability of CL was predictable. Size explained 66%, PMA 17% and renal function 9%. The use of a variable slope sigmoidal model to describe the relationship between clearance and PMA predicted an adult amikacin clearance of 3.87 L/h/70kg.
Conclusions: The explained variability of clearance and the relative contribution of the different contributors (size, PMA and renal function) is a similar magnitude with the earlier reported observations on vancomycin clearance and a variable slope sigmoidal model fitted best to predict adult amikacin clearance. These findings strongly suggest that the current model likely describes the underlying maturation of renal drug clearance. The development and subsequent validation of such models should further improve the predictability of drug clearance for drugs cleared by a similar route.

P1248 Cerebrospinal fluid penetration and pharmacodynamic exposure of meropenem prophylactically administered to neurosurgical patients

K. Ikawa, R. Tsumura, N. Morikawa, K. Ikeda, M. Shibukawa, K. Iida, K. Kurisu (Hiroshima, JP)

Objectives: Meropenem is frequently used for the treatment and prophylaxis of bacterial meningitis. However, the drug's distribution within the site of action is poorly understood. This study examined the penetration and pharmacodynamic exposure of meropenem into cerebrospinal fluid (CSF).
Methods: Meropenem (0.5 g every 8 h) was prophylactically administered to six patients who underwent neurosurgery and external lumbar drainage for the management of cerebrovascular diseases. Lumbar CSF and venous blood samples were obtained at the end of the infusion (0.5 h) and 1, 1.5, 2.5, 4.5, and 8 h thereafter. Pharmacokinetic data in CSF and plasma were estimated noncompartmentally, analysed using a 3-compartment pharmacokinetic model, and used for a Monte Carlo simulation with MIC data of clinical isolates in Japan.
Results: Noncompartmental pharmacokinetic analysis demonstrated that the observed maximum concentration was 0.66 ±0.17 (mean ± SD) mg/L at 3.00±1.22 h in CSF and 29.50±6.54 mg/L at 0.5 h in plasma,

and the CSF/plasma ratio was 0.024±0.011. The area under the drug concentration-time curve (AUC 0–8 h) was 3.76±0.75 mg·h/L in CSF and 35.76±6.15 mg·h/L in plasma, and the CSF/plasma ratio was 0.109±0.035. The Monte Carlo simulation combined with compartmental pharmacokinetic modeling showed that the probabilities of achieving the bacteriostatic exposure target in CSF (30% of the time above the MIC) for 0.5 g every 8 h (0.5-h infusion) were 99.8% against a *Streptococcus pneumoniae* population (MIC50 = 0.06 mg/L; MIC90 = 0.5 mg/L) and 99.6% against a *Haemophilus influenzae* population (MIC50 = 0.12 mg/L; MIC90 = 0.5 mg/L), respectively. The prophylactic regimen of 0.5 g every 8 h was considered to provide sufficient bacteriostatic exposure in CSF for the two major meningitis pathogens.

Conclusion: These results expand our knowledge of the rate and extent of meropenem penetration into the cerebrospinal fluid and space, and provide a pharmacokinetic-pharmacodynamic rationale for design of a meropenem regimen to prevent bacterial meningitis.

P1249 Altered pharmacokinetics of linezolid in patients with severe burn injuries

C. Vinsonneau, A.M. Lovering, J. Stephanazi, L. Hovsepian, H. Carsin, G. Birraux, P. Bret, R. Le Floch (Paris, FR; Bristol, UK; Clamart, Nantes, FR)

Background: Significant physiological changes occur in patients with major thermal burn injuries and result in alterations to the pharmacokinetics (PK) of many agents. These changes usually result in increased drug clearance and therefore it is necessary to increase the dosage of many antiobiotics. Today there is no data available describing the pharmacokinetics of linezolid (LZD) in burn patients and thereby whether doses need to be adjusted in these patients.

Methods: LZD PK were studied in 8 patients with severe burn injuries compared to 8 healthy volunteers matched for gender and weight. Mean (SD) demographic factors for the patients and volunteers were, age 37.0 (11.1) y vs. 37.6 (9.0) y; weight 64.0 (10.7) kg vs. 68.5 (9.4) kg and burnt area 41.0 (20.7) % vs. 0 (0) %. 600 mg LZD was administered as a 1 h infusion and both blood and urine samples were taken up to 72 h post dose and assayed by a validated HPLC method. PK parameters were determined by non-compartmental analysis.

Results: The mean (SD) PK parameters determined for LZD in the patients and healthy volunteers were: AUC0–∞ 42.5 (24.0) mg.h/L vs. 98.1 (29.2) mg.h/L, half life 2.1(1.0)h vs. 4.8(2.0)h and Vss 50.8 (16.8) L vs. 39.6 (5.7) L, respectively. The differences for AUC and T1/2 were statistically significant (P = 0.016; Wilcoxon signed rank sum test), but not the difference for Vss (P = 0.383). Mean concentrations of LZD dropped below the susceptibility breakpoint (EUCAST ⩽4 mg/L) for staphylococci after 4 h in the patients and 10 h in the volunteers.

Conclusion: The PK of LZD were significantly altered in patients with major burn injuries as compared to healthy volunteers. The drug exposure, as assessed by AUC, was reduced by approximately 50% in burn patients suggesting that a different dosage schema might be required. Today it is not clear how this possible difference should be addressed, but for a drug that has time-dependent efficacy, it may be more appropriate to increase the frequency of administration rather than the dose administered.

P1250 Bioequivalence of marketed voriconazole oral suspension and tablet formulations: results of a three-period, crossover, multiple-dose study

N. Wood, B. Damle (Sandwich, UK; New York, US)

Objectives: Voriconazole (VORI) is an extended-spectrum antifungal drug widely used in the treatment of opportunistic fungal infections, including invasive aspergillosis and candidaemia. An oral suspension of VORI has been developed for use in adult patients who are unable to swallow marketed tablets, and in paediatric patients. This study assessed the bioequivalence of two batches of VORI oral suspension (batches differing only in drug particle size of the in-going drug substance) relative to VORI tablet. The safety and tolerability of the two formulations were also compared.

Methods: This was a randomised, three-period, crossover, multiple-dose study, carried out in fasted healthy male subjects aged 18–45 years. In each study period, subjects received VORI tablet or suspension (batch 1 or 2) 400 mg twice daily on Day 1 followed by 200 mg twice daily for 5.5 days; study periods were separated by a wash-out period of at least 7 days. Blood samples were taken on Day 7 to assay VORI plasma concentrations at specified times up to 12 hours post-dose. The safety analysis included assessment of adverse events, clinical laboratory tests and physiological parameters.

Results: Pharmacokinetic data were obtained for 48 subjects randomised to receive VORI: suspension batch 1, n = 43; suspension batch 2, n = 44; tablet, n = 45. Statistical analysis of these data (Table) demonstrated that both VORI suspension batches were bioequivalent to the tablet formulation, as 90% CIs for suspension batch 1/tablet and suspension batch 2/tablet ratios both fell within the standard AUC_{tau} and C_{max} equivalence ranges of 80–125%. The incidence and types of adverse events were consistent with the known VORI safety profile, with similar safety profiles across the three drug formulations.

Conclusion: Both batches of VORI oral suspension were bioequivalent and similar in safety to VORI tablet. The availability of VORI oral suspension can provide further flexibility in patient care, an important component in the successful management of invasive fungal infections.

Table: Statistical analysis of pharmacokinetic parameters of voriconazole suspension and tablets on Day 7.

Parameter	Adjusted means*		Ratio or Difference†	90% CI
	Suspension batch	Tablet		
Suspension batch 1 vs tablet				
AUC_τ (ng·h/ml)	11718	11478	Ratio: 102%	(99, 106)
C_{max} (ng/ml)	2253	2166	Ratio: 104%	(98, 111)
T_{max} (h)	0.95	1.39	Difference: 0.44 h	(–0.66, –0.23)
Suspension batch 2 vs tablet				
AUC_τ (ng·h/ml)	12067	11478	Ratio: 105%	(102, 109)
C_{max} (ng/ml)	2488	2166	Ratio: 115%	(108, 122)
T_{max} (h)	0.82	1.39	Difference: 0.57 h	(–0.78, –0.36)

AUC_τ = area under the plasma concentration time curve over dosing interval τ; C_{max} = maximum observed plasma concentration; T_{max} = time to first occurrence of C_{max}.
*Adjusted means are geometric for AUC_τ and C_{max}, and arithmetic for T_{max}.
†Ratio = suspension/tablet. Difference = suspension minus tablet.

P1251 Effect of voriconazole on the pharmacokinetics of reduced doses of sirolimus

B. Damle, A. Fang, R. LaBadie, F. Jen, R. Swanson, P. Glue, J.H. Antin (New York, Boston, US)

Objectives: Sirolimus (SIR) is metabolised by CYP3A4/5, while voriconazole (VORI) inhibits CYP3A4-mediated drug clearance. Systemic exposure of SIR (with standard 2 mg dose) is significantly increased by VORI coadministration. Hence, concomitant use of VORI and SIR is contraindicated. Our aim was to determine SIR dose adjustments, when coadministered with VORI, which result in exposures similar to monotherapy.

Methods: This was an open-label, nonrandomised, parallel-group, multiple-dose, fixed-sequence, 2-period study in 30 healthy males. The effect of steady state oral VORI on the multiple-dose pharmacokinetics (PK) of 3 reduced doses of SIR (oral solution; 0.25, 0.15 and 0.10 mg/d; n = 30/group) was investigated relative to the standard dose alone in the same subjects. Serial blood samples were collected at predose and over a 24-h interval on the final day of each study period; SIR and VORI concentrations were determined by LC/MS/MS. PK were determined by noncompartmental methods. A modelling approach was used to estimate the effect of staggered VORI dosing on steady state SIR levels.

Results: The changes in PK parameters when reduced doses of SIR were coadministered with VORI are shown in the table.

Treatment		AUC_{24} (ng·h/mL)	C_{max} (ng/mL)	C_{min} (ng/mL)	$t\frac{1}{2}$ (h)
Group 1	Day 4	93.6	10.1	2.5	17.9
	Day 9	125.6	8.3	4.3	30.5
Group 2	Day 4	82.0	9.3	2.0	18.9
	Day 9	100.4	5.6	3.4	32.6
Group 3	Day 4	106.6	11.3	2.6	20.6
	Day 9	86.6	4.6	3.2	36.4

Mean PK parameters of SIR. SIR was given at standard dose on Days 1–4 and at reduced dose on Days 6–9: 0.25 mg/d (group 1), 0.15 mg/d (group 2) and 0.10 mg/d (group 3). Standard-dose VORI was given on Days 6–9.

A decrease in SIR AUC24 of 16% (90% CI: 8%-24%), relative to standard-dose SIR was observed for 0.10 mg SIR with concomitant VORI, resulting in suboptimal exposure to SIR. Conversely, AUC24 was increased by 23% (90% CI: 11%-36%) and 36% (90% CI: 21%-54%) with SIR doses of 0.15 and 0.25 mg, respectively, resulting in slightly higher exposure to SIR than with standard-dose monotherapy. Across all 3 study groups, SIR C_{max} values were lower by 19%-59%, Cmin values were higher by 9%-64% and $t\frac{1}{2}$ values were higher by 70%-77% compared with standard-dose monotherapy. SIR had no effects on VORI PK. Modelling indicated that staggering dosing of VORI and SIR is likely to decrease the magnitude of interaction.
Conclusion: It is possible to coadminister reduced doses of SIR with VORI to achieve systemic exposures similar to standard-dose SIR monotherapy. While not specifically tested in this study, our results suggest that a 90% reduction in SIR dose would maintain SIR therapeutic levels when coadministered with VORI. Our results are applicable only when both drugs are administered simultaneously orally. Further studies assessing the PK, safety and efficacy of coadministration of reduced SIR doses and VORI in transplant patients are necessary.

P1252 Population pharmacokinetic analysis of moxifloxacin in patients undergoing cardiac surgery

M. Blunck, H. Stass, L. Rupprecht, B. Flörchinger, M. Hilker, F. Kees, F.X. Schmid (Wuppertal, Regensburg, Krefeld, DE)

Objective: A population pharmacokinetic (PPK) model for moxifloxacin (MXF) in the serum, heart tissue (right atrium and ventricle) and aortic root of patients undergoing scheduled aortic valve surgery (AVS, Ross procedure) was to be developed including an estimate of the influence of the cardiopulmonary bypass and patient characteristics on the PPK of MFX.
Methods: The PPK model was based on data from 20 patients who had undergone AVS. Patients underwent surgery at 3, 7, 10, 13 or 20 h after start of a 1 hour 400 mg MFX infusion. Data collected included MFX/serum concentration profiles and tissue samples. Demographic, renal parameters, and the AVS procedure were tested as covariates using the NONMEM software.
Results: The PPK of MFX was described by a three-compartment model (population mean [% relative standard error] volume of central compartment Vc=57 L [18%], elimination rate ke=0.17 1/h [14%], clearance CL =9.8 L/h) with a moderate inter-individual coefficient of variance of 20% for Vc and 26% for ke, about half of which was attributable to an effect of weight and sex on Vc and the effect of renal function (serum creatinine) on ke. The model implied that the MFX serum concentrations were transiently reduced by about 20% during application of the priming fluid of the cardiopulmonary bypass. The tissues behaved as small compartments directly linked to the central compartment, resulting in swift attainment of high levels of MFX in tissue. Equilibrium with serum was reached rapidly in the right atrium and right ventricle, indeed within 1 hour of the end of infusion. The aortic root tissue reached equilibrium within 2–5 hours. The latter is in line with differences in perfusion and comparable with other fast equilibrating tissues.
Conclusion: Despite the sparse sampling, a consistent model was achieved that describes the fast penetration of MFX into cardiac tissue. The PPK results support the possible use of MXF in infectious endocarditis.

P1253 Faropenem pharmacokinetics in AOM children following oral administration of faropenem medoxomil

A. Arguedas, R. Dagan, G. Rincon, E. Wang, R. Tosiello, R. Echols, J. Li, A. Beaudry, S. Gill (San Jose, CR; Beer Sheva, IL; Louisville, US)

Objectives: Faropenem medoxomil (FM) is a novel oral prodrug antibiotic with in-vitro activity against common repiratory tract pathogens including activity against penicillin and MDR resistant *S. pneumoniae*. The objective of this dose-ranging study was to evaluate faropenem (FAR) pharmacokinetics in paediatric AOM.
Methods: In this phase II study, children with AOM (0.5–7yrs) received FM BID for 10 days. Blood was collected from 179 children at 0.5, 1, 2 and 4 hours post dose 1. In addition, a single blood sample was obtained at study Visit 2 (study Days 4–6) in 314 children over a range of time following dose administration on that day. Doses evaluated were 7.5, 15, 30 and 40 mg/kg. FAR plasma concentrations were determined using a validated LC-MS/MS assay with a lower limit of quantitation of 2.5 ng/mL. Individual subject FAR pharmacokinetic parameters on Day 1 were calculated using non-compartmental analysis.
Results: FAR plasma pharmacokinetics following oral administration of FM on Day 1 demonstrated increasing exposure with increasing dose. Median FAR Cmax values were 16.5, 26.0, 54.3, and 57.9 mg/L at doses of 7.5, 15, 30, and 40 mg/kg, respectively. Corresponding median AUC0–4 values were 20.4, 42.3, 93.0 and 112 mg*h/L, respectively. FAR plasma concentrations at Visit 2 were similar to those observed on Day 1.
Conclusions: FAR pharmacokinetic data in paediatric subjects confirmed dose-linearity of AUC, while C_{max} values, although approximately linear, trended toward less than expected increases with increasing dose. Comparison of paediatric values with those observed in adults showed an increase of 1.8-fold in CL/F. As expected with a drug that is renally eliminated, a correlation was observed between increasing AUC with decreasing CrCl. No gender or age (0.5 to 7 years) related effects were observed with FAR pharmacokinetics. Similar FAR plasma concentrations were observed following repeat dosing indicating no substantial changes in FAR pharmacokinetics over time.

P1254 The pharmacokinetics of posaconazole administered orally versus via a nasogastric tube in healthy subjects

J. Varkey, G. Krishna, D. Vickery, L. Ma, X. Yu, D. Malavade, M. Goodwin, J. Perfect, E. Dodds Ashley, E. Power (Durham, Kenilworth, US)

Objectives: The pharmacokinetics (PK) of single-dose posaconazole (POS) given either orally (PO) or via nasogastric (NG) tube were evaluated in healthy subjects.
Methods: This was an open-label, comparative, cross-over study in healthy subjects. In random sequence, subjects received POS 400 mg PO or NG (Day 1) followed by a 7-day washout and then a second dose of POS 400 mg via the alternate route on Day 8. POS was administered 5–10 minutes after completion of 8 fluid oz of Boost Plus® administered via the same route as POS in each dosing period. Blood samples for POS plasma concentration determination by LC/MS-MS method were obtained at prespecified time points over a 12-h period following POS administration. The log-transformed PK parameters from a noncompartmental analysis were statistically analysed using an ANOVA model.
Results: Fifteen subjects (male and female) completed both treatment periods. Cmax and AUC values for NG tube administration were 81%

and 76% of those observed following PO administration. The median Tmax values were the same for both routes, indicating that rates of absorption of POS is unaffected by PO and NG tube routes of administration. The mean apparent clearance (CL/F) was 12% higher for NG tube than that for the oral route of administration. It is likely that this difference is to due to differences in the amount of POS absorbed from the different administration routes. The elimination as indicated by terminal phase half-life (t1/2) of POS would be expected to be similar regardless of the route of administration. Consistent with this, the t1/2 values were similar between PO administration and NG Tube administration. PO and NG tube administration of POS 400 mg was found to be safe and well tolerated when administered to healthy adult subjects.

Table 1: Mean and % CV of POS PK parameters in healthy subjects following administration of a 400 mg dose (suspension) orally (PO) or via a NG Tube 5–10 minutes after receiving a nutritional supplement (Boost Plus®)

Parameter	NG Tube		PO	
	Mean	% CV	Mean	% CV
Cmax, ng/mL	266	45.2	324	49.7
Tmax, h	4.0[a]	2.0–6.0[b]	4.0[a]	3.0–12.0[b]
AUC(I), ng·h/mL	8402	44.8	10866	53.4
t1/2, h	23.7	30.7	21.6	38.9
CL/F, mL/h	594109	52.3	49345	54.2

[a]Median; [b]Range.

Conclusion: In healthy subjects, NG tube administration of a single dose of 400 mg of POS (suspension) appears to lead to Cmax and AUC values that are about 80% of those observed following PO administration when both were administered 5–10 minutes after 8 fluid oz of Boost Plus®.

P1255 Pivmecillinam: estimation of adequate dosage for susceptible and ESBL-producing *E. coli* by Monte Carlo PK/PD simulation

K.S. Jensen, A.S. Henriksen, N. Frimodt-Moeller (Copenhagen, Ballerup, DK)

Objectives: Pivmecillinam (PM) is widely used in the Scandinavian countries for treatment of urinary tract infections (UTI). It is highly active against non β-lactamase producing *E. coli* with MIC values around 0.125–0.5 mg/l, but also retains activity against β-lactamase producing, even many ESBL-producing, *E. coli*, where the MIC has increased to a level of 1–2 mg/l. We therefore wanted to estimate the probability of target attainment in serum for a number of dosage regimens for the two different MIC levels.

Methods: Pharmacokinetic data for mecillinam concentrations after per oral dosing of 400 mg PM (equivalent to 273 mg mecillinam) were on file at LEO Pharma. 11 measurements of serum concentration within 8 hours from intake were recorded in 17 individuals (age 26.6±7.3 years, weight 73.0 ±13.9 kg). The NPAG program was used to fit a linear compartment model (seven state variables, six PK parameters) to the data whereby mean values as well as the covariance matrix for the PK parameters were obtained. Monte Carlo simulations were then made with the compartment model assuming lognormal as well as nonparametric (empirical) frequency distributions for the PK parameters. Results were obtained on the probability of target attainment with respect to a Time>MIC of 40% as usual for most β-lactam antibiotics. Since the drug concentrations in serum are most important for treatment of renal infection, these were used as surrogate markers in this PK/PD analysis.

Results: After the parameter estimation process, the compartment model was able to reproduce the measured serum concentrations with satisfactory precision. With a MIC of 0.25 mg/l, a Time>MIC of 40% (for an unbound fraction eq. to 90% of total dose) could be reached for 95% of the simulated population on a 400 mg PM dose TID. The same population coverage (95%) required 800 mg QID if the MIC was around 1 mg/l.

Conclusion: The lower dose fits the dosage regimen presently recommended for treatment of upper UTI. The high dose is still manageable since PM has low toxicity; a total dose of 60 mg/kg is tolerated in mature humans. Based on the simulation results, a standard PM dose of 400 mg TID is recommended for upper UTI. For ESBL-producing *E. coli*, if clinical data allow, the dose should be increased to 800 mg QID.

P1256 Three-times weekly teicoplanin in the outpatient treatment of chronic infections

C. Tascini, E. Tagliaferri, A. Di Paolo, L. Ciofi, M. Del Tacca, P. Lambelet, F. Menichetti (Pisa, IT)

Background: Several types of infections deserve prolonged treatment for months. In the setting of infections caused by multidrug resistant Gram-positive cocci, outpatient treatment is difficult to perform especially in the case of exclusive parenteral options.

Method: We enrolled in this study with teicoplanin three-time weekly patients who need to be treated with teicoplanin for prolonged time. After a loading dose of 7 mg/Kg everyday for 15 days, patients received 12 mg/Kg on Monday, Wednesday and Friday in an outpatient setting. Trough and peak concentrations were determined by fluorescence polarisation immunoassay (Seradyn, USA). Serum concentrations of teicoplanin were also determined in a control group of inpatients receiving teicoplanin (7 mg/Kg) everyday.

Results: Thirty-three patients were enrolled: 14 with vertebral osteomyelitis, 11 with infected orthopaedic implants, 5 with osteomyelitis, 3 with arterial prosthetic infections. Teicoplanin was administered empirically in 10 patients, for MRSA infections in 12 patients, for MR-CNS infections in 9 patients, for MSSA infection in 1 patient and for *Propionibacterium* spp. infection in 1 patient. The duration of treatment ranged from 60 to 360 days (median 150±84 days). Cure was obtained in 21 (63%) and improvement in 12 (37%) cases. Trough and peak serum concentrations in three-time weekly patients were 16.2±7.2 and 58.7±14.4, respectively. In the control group trough and peak serum concentrations were 18.9±13.6 and 52.2±27. Adverse effects occurred in 6 patients and caused discontinuation of treatment only in 1 patient.

Discussion: Three-time weekly teicoplanin was effective in the treatment of chronic infections. This way of administration yields the same serum levels of teicoplanin when the drug is administered everyday at standard doses, while adverse effects are rare and mild.

P1257 Value of pharmacokinetic/pharmacodynamic in dose management of ceftazidime and imipeneme in ICUs

M. Coudrot, A. Carricajo, S. Guyomarc'h, J. Morel, C. Auboyer, F. Zeni, G. Aubert (Saint-Etienne, FR)

Objectives: the purpose of our study was to assess the value of serum assay of ceftazidime (CAZ) and imipeneme (IMI) in patients in the intensive care unit (ICU) of the Saint-Etienne University Teaching Hospital and in other ICUs in the region with regard to optimisation of treatment management.

Methods: Between 01/11/05 and 31/10/07, in patients hospitalised in ICUs, not on dialysis and undergoing treatment with CAZ given in a continuous infusion or with IMI (non-continuous), serum assay of the respective antibiotics was performed 36 hours after the start treatment using a single serum sample for CAZ and determination of trough and peak concentrations for IMI. Assays were performed using the microbiology technique with results 18 hours after sample collection. CAZ 2 g was given systematically in a bolus at the start of treatment.

Results: assay was performed in 81 and 95 patients respectively for CAZ and IMI. Mean patient age was 66 years (19 to 89 years) and mean weight was 73 kg (33 to 122 kg). The dosage was between 1 g and 6 g/24 h for CAZ and between 500 mg and 6 g/24 h for IMI. The mean serum CAZ concentration was 47.6 mg/L (7.4 to 162.3 mg/L).

Serum CAZ concentrations were as follows: 35 to 65 mg/L in 37% of patients, <35 mg/L in 43.2% and >65 mg/L in 19.8%. Infection was established in 61 patients, with 52 strains of *P. aeruginosa* detected. The serum concentration/MIC ratio was $\geqslant$5 for 84.4% of patients and >10 for 65.6% of patients. Trough concentrations of IMI were <0.5 mg/L for 14.7% of patients, between 0.5 and 2 mg/L for 43.2%, and >2 mg/L for 42.1%. The mean peak concentration of IMI was 19.9 mg/L (3 to 78 mg/L). Infection was recorded in 52 patients, including 22 *Enterobacter* spp. and 12 *P. aeruginosa*. Antibiotic dosage was adjusted respectively for CAZ and IMI in 19.8% and 28.4% of patients based on the initial assay results.
Conclusion: Our study shows that assays are needed in ICUs to confirm the efficacy of time-dependent antibiotics, to avoid treatment toxicity, to achieve efficacy as rapidly as possible and to avoid selection of resistant mutants, particularly in strains having limited susceptibility to antibiotics.

P1258 Moxifloxacin does not require dosage adjustment in patients with severe hepatic insufficiency

J. Barth, D. Jaeger, R. Mundkowski, B. Drewelow, T. Welte, O. Burkhardt (Halle/Saale, Rostock, Hannover, DE)

Objectives: Severe bacterial infections such as spontaneous bacterial peritonitis (SBP), pneumonia, or sepsis are well-described life-limiting complications in patients with advanced liver cirrhosis. Pharmacological and microbiological characteristics make moxifloxacin an attractive option in the treatment of such infections. On the other hand, since moxifloxacin is predominantly metabolised by the liver, a drug accumulation theoretically can not be excluded in patients with advanced liver insufficiency. Due to a lack of pharmacokinetic data the therapeutical use of moxifloxacin is currently not recommended in this patient population.
Patients and Methods: In a single-centre, prospective, open-label study, 9 adult cirrhosis patients with severe liver insufficiency (Child–Pugh class C) and an infection (pneumonia or SBP) were treated with 400 mg moxifloxacin infusion once a day. On days 1 and 3 drug concentrations in serum and ascites were determined before and at different time points up to 24 h after medication with a validated HPLC method.
Results: On day 1, serum concentrations of moxifloxacin decreased from a geometric mean of 3.60 mg/L at 1 h to 0.62 mg/L at 24 h. On day 3, serum peak and trough levels showed only a moderate accumulation. The AUC values were slightly, but not statistically significant, increased on day 3. Calculations of t1/2, MRT, CLtot, and Vss also revealed no significant differences between days 1 and 3. Mean concentrations of moxifloxacin in ascitic fluid were 1.47 mg/L at 3.0 h and 1.39 mg/L at 6.0 h on day 1, and 2.07 mg/L at 3.0 h and 1.88 mg/L at 6.0 h on day 3. There were no differences in mean ascites/serum ratios between days 1 and 3.
Conclusions: PK parameters of intravenous moxifloxacin in patients with advanced liver cirrhosis differed only marginally from those from healthy control groups given in the literature. After multiple dosing only a moderate drug accumulation was seen. Therefore, we conclude that a dose adjustment is not necessary in this patient group. In addition to this, ascitic fluid reached bactericidal levels of moxifloxacin for common bacteria found in spontaneous bacterial peritonitis.

P1259 Penetration of moxifloxacin into the tissue of heart and aortic root of patients

L. Rupprecht, B. Flörchinger, M. Hilker, F. Kees, F.X. Schmid (Regensburg, DE)

Objective: Moxifloxacin is clinically used in respiratory tract and skin and soft tissue infections. The aim of the present study was to provide pharmacokinetic data for the possible use of moxifloxacin in infectious endocarditis.
Methods: 20 patients (12m/8f) with age (median, range) of 53, 23–64 years, weight 84, 61–106 kg, height 175, 156–195 cm, BMI 27.1, 20.7–48.8 kg/m2) undergoing scheduled aortic valve surgery (Ross procedure) were enrolled into the study. During surgery, tissue specimens were sampled in 4 patients each 3, 7, 10, 13 and 20 hours after start of a 1hour infusion of moxifloxacin 400 mg. Blood was sampled in order to compare tissue and concomitant serum concentrations. Moxifloxacin was determined by HPLC and fluorimetric detection in serum and tissue homogenate.
Results: The serum concentrations (median) of moxifloxacin were 1.9 mg/L after 3 hours and 0.54 mg/L after 20 hours. Moxifloxacin penetrated fast into different structural compartments of the heart. The peak concentrations in atrium and ventricle were measured already 3 hours after the start of the 1hour infusion, the penetration into the aortic root was somewhat slower. The global tissue concentration/serum ratio was 3.4–6.8 in ventricle, 2.6–4.8 in atrium and 2.2–2.8 in aortic root (see Table).

Tissue concentrations (median, range), concomitant serum concentrations and median tissue to serum ratio (a/s right atrium/serum, v/s right ventricle/serum, ar/s aortic root/serum) in patients (n = 4/group) following a 1 hour infusion of moxifloxacin 400 mg

t (h)	serum (mg/L)	atrium (μg/g)	ventricle (μg/g)	aortic root (μg/g)	a/s	v/s	ar/s
3	1.90, 1.41–2.39	8.93, 3.25–15.5	12.8, 5.53–36.5	4.66, 2.41–6.93	4.8	6.8	2.5
7	1.05, 1.03–1.44	3.14, 2.91–4.59	5.90, 5.46–6.62	2.50, 2.41–5.13	3.0	5.4	2.4
10	1.48, 0.99–1.60	2.77, 2.08–3.47	5.00, 3.50–6.69	2.37, 2.09–3.52	3.0	5.4	2.8
13	0.88, 0.53–1.44	2.07, 1.33–4.30	3.43, 1.60–5.03	1.96, 0.97–3.02	2.7	3.4	2.2
20	0.54, 0.48–0.71	1.39, 1.12–2.00	2.34, 2.14–2.63	1.42, 0.96–1.85	2.6	4.2	2.3

Conclusion: From the pharmacokinetic point of view, moxifloxacin seems to be adequate for the treatment of infectious endocarditis, caused by susceptible pathogens.

P1260 Comparison of the activity of ciprofloxacin vs. levofloxacin against *Pseudomonas aeruginosa* by the continous antibiotic gradient method: a pharmacodynamic approach in respiratory infection

H. Drugeon, E. Bigeard, M.E. Juvin (Nantes, Angers, FR)

Objectives: The continous antibiotic gradient method allows to assess the risk of resistant mutant selection. In this study, the activity of levofloxacin (LVX) was compared to that of ciprofloxacin (CIP) against 50 clinical isolates of *Pseudomonas aeruginosa*. A pharmacodynamic approach was performed in order to evaluate this risk in the respiratory tract.
Methods: The antibiotic gradients were prepared in Mueller Hinton agar plates by applying filter paper strips containing different concentrations of antibiotic at regular intervals at the surface of the plate. Six different inocula, from 10–5 to 10–11 CFU/ml, were tested for each strain. Two parameters, the length of homogenous growth and the length to the most resistant colonies were measured and converted into antibiotic concentrations: boundary concentration (BC) and no growth concentration (NGC) respectively. The pharmacodynamic approach was perfomed by dividing the antibiotic concentrations observed in the epithelial lining fluid (ELF) by the NGC50. The following concentrations in ELF observed at 4 hours were used: 22 mg/L with levofloxacin 750 mg once daily or 500 mg bid and 1.9 mg/L with ciprofloxacin 500 mg bid respectively.
Results: The evolution of mutant selection was parallel between CIP and LVX: NGC50 increased by 3–5 fold from a weak to an heavy inoculum. This value refered to the observed in situ antibiotic concentrations showed a clear superiority of levofloxacin vs. ciprofloxacin, confirmed by the individual analysis of each strain.

	Inoculum				
Dilution factor	10^{-4}	10^{-3}	10^{-2}	10^{-1}	Pure
NGC50 CIP	0.84	1.03	1.76	2.02	2.31
NGC50 LVX	1.5	2.9	5.1	6.8	9
CP/NGC50 CIP	2.3	1.8	1.1	0.9	0.8
CP/NGC50 LVX	14.7	7.7	4.3	3.2	2.4

Conclusion: the in vitro selection of *P. aeruginosa* resistant mutants is similar between levofloxacin and ciprofloxacin. The emergence of resistant mutants was observed with the same frequency and the MIC increase is close. Taking into account the lung concentrations, levofloxacin shows a clear superiority over the ciprofloxacin.

P1261 Analyses supporting phase 2 clinical trial dose selection for zabofloxacin in community-acquired pneumonia

P. Ambrose, S. Bhavnani, R. Jones, M. Wikler (Albany, North Liberty, San Diego, US)

Objective: To conduct analyses in support of dose selection for zabofloxacin in Phase 2 community acquired pneumonia (CAP) studies. Phase 2 clinical trials will be initiated for zabofloxacin, a new antimicrobial agent belonging to the fluoroquinolone class. Zabofloxacin has high in vitro activity against pathogens associated with CAP/respiratory tract infections, including penicillin- and levofloxacin-non susceptible strains of *Streptococcus pneumoniae*.
Methods: Monte Carlo simulation (5,000 iterations) using Phase 1 pharmacokinetic (PK), protein binding, and non-clinical PK-PD data were utilised to determine the probability of attaining free-drug AUC:MIC target thresholds for daily doses of zabofloxacin ranging from 50 to 800 mg. PK data were derived from a randomised, placebo-controlled, ascending multiple-dose (dose range 200–800 mg daily orally for 7 days) study in 24 healthy volunteers. Zabofloxacin clearance (CL/F) was linear over the dose range studied, with a mean (SD) of 36.3 (12.8) L/hour. A point estimate of zabofloxacin binding to serum proteins of 77%, as estimated by ultra-filtration methodology, was used in the simulations. Free-drug AUC:MIC was calculated as the product of f, where f is the fraction unbound, and dose/CL/F. A log normal distribution for CL/F was assumed. Resultant free-drug AUC values were divided by fixed clinically relevant MIC values for zabofloxacin against pneumococci ranging from 0.008 to 0.25 mg/L (MIC50/90/99 for zabofloxacin against *S. pneumoniae*: 0.015/0.03/0.06 mg/L). The free-drug AUC:MIC target threshold evaluated in these analyses was 30, which was associated with complete eradication of *S. pneumoniae* from the lungs of immuno-competent mice (inoculated with 106 CFU) after treatment with zabofloxacin.
Results: The probabilities of PK-PD target attainment are presented in the Table.

	MIC Range (mg/L)					
Daily dose (mg)	0.008	0.015	0.03	0.06	0.125	0.25
50	0.884	0.201	0	0	0	0
100	0.999	0.876	0.195	0	0	0
200	1.0	0.998	0.880	0.190	0	0
300	1.0	1.0	0.991	0.626	0.045	0
600	1.0	1.0	1.0	1.0	0.579	0.034
800	1.0	1.0	1.0	1.0	0.852	0.167

Note that for daily doses of 300 mg or greater, the probability of PK-PD target attainment approaches 1.0 for MIC values as high as 0.03 mg/L, the MIC90 for zabofloxacin against *S. pneumoniae*.
Conclusion: These analyses support a 300 mg (or greater) once-daily dose-regimen for zabofloxacin for the treatment of CAP associated with *S. pneumoniae*.

P1262 Treatment optimisation using vancomycin on the critical patient

J.P. Baptista, P. Casanova, P. Martins, J. Pimentel (Coimbra, PT)

Introduction: It is more difficult to optimise antibiotic serum levels in critical patients (P). The aim of this study was to assess the therapeutic levels (20–30 μg/ml) of vancomycin (V′) on septic critical P on continuous intravenous infusion.
Materials and Methods: The study was carried out on 175 consecutive treatments in P with severe sepsis or septic shock, in a multipurpose ICU (20 beds) over 30 months. P were divided in to different categories according to degree of renal failure (RF) based on the RIFLE classification (glomeular filtration rate <60 ml/m); correlation of demographic characteristics and renal function with serum levels; evaluation of the population with and without sufficient levels of V′. Statistics: t-student test, Mann-Whitney and Pearson coefficient trending to $p < 0.05$.
Results: Average age 55.4 yrs, 137 men (78%), average APACHE II and SAPS II of 17 and 41.9 respectively. The average doses of vancomycin were 15.2 mg/kg for initial loading dose and 29.2 mg/kg on day 1 infusion. Average V′ levels for day 1, 2 and 3 were 19.2, 22.1 and 23.9 μg/ml with higher levels in women, independent of renal clearance, total body surface area and the dose of vancomycin measured in the first 24 hours: $p = 0.02$ for the 1st and 2nd day (14/18.3; 16.4/22.4). Over the total treatment period (1274 days) the V′ levels were above 20 μg/ml for 66% of the period and above 25 μg/ml for 40%. RF occurred in 31 P (17%) of which 12 (39%) had normal creatinine serum levels. In 71 P with V′1 > 20 (37%), RF occurred in 25 P (35%). The V′1, 2 and 3 were higher in the group with RF ($p < 0.05$) compared to the rest (17/27, 21/29, 23/30). The correlations between V′1, clearance and age were moderate ($r = -0.6$, $p < 0.01$, $r = 0.44$, $p < 0.01$), in the group without RF. Supratherapeutic levels (V > 30) occurred in 14 P (8.3%) of which 12 (86%) had RF and 36% (6 P) had normal renal function.
Conclusions: Critical Septic P without RF showed sub-optimum levels of V′1 and V′2 (<20) in a high percentage of cases (67% and 49% respectively). Women showed higher levels of V′, and V′varied proportionally with age. Toxic levels occurred mainly in P with RF. For P without RF, doses of 15 mg /kg (loading) and 30 mg /kg/day (maintenance) seem to be insufficient on day 1. In critical patients, RF is underdiagnosed, as serum creatinine shows low sensitivity for diagnosis, and so daily clearance should be used to adjust the initial dose of antibiotics with preferential renal excretion

P1263 Administartion of probiotics decrease the risk of sepsis by bloodstream infections in patients with multiple injuries

K. Kotzampasi, E.J. Giamarellos-Bourboulis, K. Kanellakopoulou (Thessaloniki, Athens, GR)

Background: A recent randomised clinical trial of our group (Kotzampassi et al. World J Surg 2006) has disclosed considerable reduction of the infective sequelae after oral administration of Symbiotic FORTE, the latter being a preparation of Pediococcus pentoseceus 5–33:3, *Leuconostoc mesenteroides* 32–77:1, *Leuconostoc paracasei* ssp 19, and *Leuconostoc plantarum*. The effect of treatment on microbiology of the study population has not been published and it is presented herein
Methods: Patients were remaining intubated and they were administered either placebo or probiotics for 15 days after admission. Upon presentation of signs of sepsis, a complete diagnostic work-out was done comprising cultures of blood, urine and tracheobroncial secretions (TBS).
Results: Thirteen patients of the placebo group developed bloodstream infection (36.1%) compared to seven patients of patients treated with SynbioticFORTE (19.4%, LR: 16.96, p: 0.009). From the 13 placebo-treated patients with bloodstream infection all developed signs of sepsis as opposed to the remaining 23 patients without bloodstream infection where only 11 developed sepsis (OR: 2.182, p: 0.002). From the seven SynbioticFORTE-treated patients with bloodstream infection five developed signs of sepsis as opposed to the remaining 29 patients without bloodstream infection where 12 developed sepsis (OR: 1.268, p: 0.219). The time to progression to primary bacteraemia was longer among patients treated with SynbioticFORTE compared to placebo (p: 0.0237 between groups). Twelve (33.3%) and five (13.9%) placebo-treated and probiotic-treated patients respectively developed ventilator-associated pneumonia with *Acinetobacter baumannii* as a bacterial cause (p: 0.047 between groups).

Conclusions: Probiotics contained in the oral formula SynbioticFORTE decrease significantly the risk for sepsis by bloodstream infections and the occurrence of VAP by *A. baumannii*. An effect on bacterial translocation may be proposed as a probable mechanism of action.

P1264 Effect of gastric pH, dosing regimen and prandial state, food and meal timing relative to dose, and gastro-intestinal motility on absorption and pharmacokinetics of the antifungal posaconazole

G. Krishna, A. Moton, L. Ma, D. Malavade, M. Medlock, J. McLeod (Kenilworth, NJ, Austin, TX, US)

Objectives: Absorption of posaconazole (POS) can be enhanced if POS suspension is taken with food or a high-fat meal; in some patients, this may not be feasible. Factors with a potential to affect POS absorption were analysed in a four-part, open-label, randomised, crossover study in healthy subjects.

Methods: Part 1 (gastric pH, n = 32): treatments were POS 400 mg single dose (SD) vs POS 400 mg SD + 12 oz ginger ale (acidic beverage) vs esomeprazole (proton pump inhibitor [PPI]) 40 mg QD, 3 days + POS 400 mg SD (Day 3) vs PPI 40 mg QD, 3 days + POS 400 mg SD + 12 oz ginger ale (Day 3). Part 2 (dosing + prandial state, n = 32): treatments (7 days each) were POS 400 mg BID + Boost (nutritional supplement) vs POS 400 mg BID while fasting vs POS 200 mg QID + Boost vs POS 200 mg QID while fasting. Part 3 (food/meal timing, n = 32): treatments were POS 400 mg SD while fasting vs before vs during vs after high-fat meal. Part 4 (gastric motility, n = 33): treatments were POS 400 mg SD + Boost vs metoclopramide (prokinetic) 10 mg TID, 2 days + POS 400 mg SD + Boost (Day 2) vs POS 400 mg SD + Boost + loperamide (anti-kinetic) 4 mg SD. Blood collection for analysis was up to 168 h post-POS dose. Log-transformed data were analysed with ANOVA.

Table: Mean (%CV) POS PK Parameters

Treatment Comparison	Cmax, ng/mL	AUC, h·ng/mL[a]
Part 1: Effect of Gastric pH (n = 12)		
POS 400 mg SD	151 (58)	5930 (50)
POS 400 mg SD + Ginger Ale	286 (55)	9890 (48)
POS 400 mg SD + PPI	76.7 (37)	4000 (39)
POS 400 mg SD + PPI + Ginger Ale	93.3 (34)	4510 (30)
Part 2: Effect of Dosing Regimen [BID/QID] and Prandial State (n = 12)		
POS 400 mg BID Alone (7 days)[b]	982 (62)	52300 (89)
POS 400 mg BID + Boost (7 days)[b]	1590 (61)	80600 (73)[c]
POS 200 mg QID Alone (7 days)	2300 (44)	132000 (54)
POS 200 mg QID + Boost (7 days)[b]	2160 (44)	112000 (49)
Part 3: Effect of Food and Meal Timing (n = 12)		
400 mg SD Fasted	181 (106)	4540 (42)
400 mg SD Before Meal	274 (70)	10300 (66)
400 mg SD During Meal	555 (44)	21300 (48)
400 mg SD After Meal	544 (50)	21300 (48)
Part 4: Effect of Gastric Motility		
POS 400 mg SD Alone (n = 12)	303 (40)	9070 (37)[d]
POS 400 mg SD + Metoclopramide (n = 13)	232 (32)	7960 (45)[e]
POS 400 mg SD + Loperamide (n = 12)	294 (42)	11100 (52)[f]

[a]AUC to infinity for parts 1, 3, and 4; AUC to final measurable sampling time for part 2.
[b]n = 11; no concentration data for 1 subject.
[c]n = 10; no concentration data for 1 subject; missing pre-dose concentration for 1 subject.
[d]n = 9; PK parameters for 3 subjects were excluded due to extrapolated area >25% of total AUC.
[e]n = 12; PK parameters for 1 subject were excluded due to extrapolated area >25% of total AUC.
[f]n = 11; PK parameters for 1 subject were excluded due to extrapolated area >25% of total AUC.

Results: Part 1: vs POS 400 mg SD (fasting), ginger ale increased POS Cmax and AUC by 92% and 70%; higher gastric pH (via PPI) decreased POS Cmax and AUC by 46% and 32% (Table). Part 2: vs POS 400 mg BID for 7 days (fasting), POS 400 mg BID + Boost increased POS Cmax and AUC by 65% and 66%; POS 200 mg QID plus and minus Boost increased Cmax and AUC by 137% and 157% and by 136% and 161%, respectively. Part 3: vs POS 400 mg SD (fasting), POS 400 mg administered before a high-fat meal increased Cmax and AUC by 96% and 111%; administration during and after a high-fat meal increased Cmax and AUC by 339% and 382% and by 333% and 387%. Part 4: vs POS 400 mg SD + Boost, increased gastric motility (via metoclopramide) decreased Cmax and AUC by 21% and 19%, and reduced gastric motility (via loperamide) decreased Cmax by 3% and increased AUC by 11%.

Conclusion: Posaconazole absorption is substantially affected by gastric pH, prandial state, and dose administration timing. A hierarchy of strategies, including administration with/after high-fat meal, in divided doses up to QID, with a nutritional supplement, with acidic beverages, or without PPIs can maximise POS exposure if patients are likely to have decreased absorption.

P1265 The safety, tolerability, and pharmacokinetics of the antifungal posaconazole in hepatic impairment

A. Moton, L. Ma, G. Krishna, D. Malavade, R. Preston, J. McLeod (Kenilworth, Miami, US)

Objectives: To compare the pharmacokinetics (PK) of posaconazole (POS) in subjects with different degrees of hepatic impairment and in healthy subjects and to determine the safety and tolerability of a single POS dose in subjects with different degrees of hepatic impairment.

Methods: This was an open-label, parallel-group study. Thirty-six subjects were to be enrolled: up to 18 subjects with various degrees of chronic liver disease (up to 6 subjects in these categories: mild, moderate, and severe hepatic impairment) and up to 18 healthy volunteers with normal hepatic function matched with hepatically impaired subjects for race, age, height, weight, and gender. Each subject received a 400-mg single dose of POS in the morning, after a standardised high-fat breakfast. Blood samples to determine POS plasma concentrations were collected pre-dose and up to 144 h post-dose. Additional samples were to be drawn at the outpatient visits on Day 10 (approximately 216 h), Day 14 (approximately 312 h), Day 21 (approximately 480 h), and Day 28 (approximately 648 h). Samples were analysed by an LC/MS-MS method. Log-transformed PK data were analysed with an ANOVA model.

Table: Mean (%CV) POS PK Parameters

Group	Tmax[a] (h)	Cmax (ng/mL)	AUC(tf) (h·ng/mL)	AUC(I) (h·ng/mL)	Vd/F (L)	CL/F (L/h)	t1/2 (h)
Normal vs. Mild							
Normal (n = 6)	5.00 (5–6)	689 (30)	22900 (17)	23400[b] (20)	671[b] (14)	17.7[b] (20)	26.9[b] (19)
Mild (n = 6)	6.5 (5–12)	694 (41)	32800 (37)	31700[b] (40)	754[b] (33)	14.4[b] (40)	38.5[b] (28)
Normal vs. Moderate							
Normal (n = 6)	5.50 (4–8)	517 (80)	19600 (66)	22300[b] (59)	866[b] (45)	25.1[b] (67)	26.5[b] (22)
Moderate (n = 6)	5.00 (4–6)	724 (15)	24900 (23)	25700[b] (24)	621[b] (23)	16.1[b] (19)	27.3[b] (24)
Normal vs. Severe							
Normal (n = 6)	5.00 (5–6)	608 (35)	19600 (38)	18700[b] (40)	1040[b] (60)	26.0[b] (58)	27.6[b] (20)
Severe (n = 6)	9 (6–24)	403 (31)	23700 (38)	24400 (37)	1058 (39)	18.6 (41)	43.1 (43)
Normal (pooled)							
(n = 18)	5.00 (4–8)	605 (47)	20700 (41)	21500[c] (41)	857[c] (49)	22.9[c] (56)	27.0[c] (19)
Mild, Moderate, and Severe (pooled)							
(n = 18)	6.00 (4–24)	607 (38)	27100 (36)	27100[d] (35)	827[d] (41)	16.5[d] (35)	36.7[d] (39)

Note: PK Parameters of AUC(I), CL/F, Vd/F and t1/2 for 4 subjects (1 matched to moderate hepatically impaired subject, 1 matched to a severely impaired subject, and 2 matched to moderately impaired subjects) were excluded because t1/2 could not be determined.
[a]Median (range). [b]n = 5. [c]n = 15, [d]n = 16.

Results: Mean POS Cmax was greater in subjects with moderate hepatic impairment than in healthy subjects (724 vs 517 ng/mL;

Table) but was decreased in subjects with severe hepatic impairment. Mean POS exposure, or AUC(tf), was higher in subjects with hepatic impairment (32,800 h.ng/mL [mild], 24,900 h.ng/mL [moderate], 23,700 h.ng/mL [severe]) than in healthy subjects (20,700 h.ng/mL, pooled). Median Tmax observed in subjects with normal hepatic function was approximately 5 h and was delayed to 6.5 and 9 h for subjects with mild and severe hepatic impairment, respectively. Similarly, the elimination half-life (t1/2) was prolonged to approximately 39 h and approximately 43 h in subjects with mild and severe hepatic impairment, respectively. The increase in t1/2 did not significantly affect AUC compared with that in healthy subjects, especially for subjects with severe hepatic impairment. The single 400-mg POS dose was safe and well tolerated when administered to hepatically impaired and healthy subjects. No deaths or serious adverse events occurred.
Conclusion: POS exposure in patients with hepatic impairment, regardless of degree of impairment, shows considerable overlap with that in healthy subjects. Thus, these data suggest that dose adjustment of POS in patients with hepatic impairment is not necessary.

P1266 Monte Carlo simulation of ceftaroline for pharmacokinetic/pharmacodynamic target attainment and dose selection

Y. Ge, S. Liao, G. Talbot (Alameda, Somerset, US)

Objectives: Ceftaroline (CPT) is a novel, parenteral, broad-spectrum cephalosporin. CPT exhibits excellent bactericidal activity against Gram-positive organisms, including MRSA and MDRSP, as well as common Gram-negative pathogens. The objective of this study was to determine the PK/PD probability of target attainment (PTA) by Monte Carlo (MC) simulation to guide appropriate dose selection for Phase 3 studies.
Methods: MC simulation of CPT concentrations was conducted using the S-Plus program in an advanced population PK model derived from Phase 1 (a single-/multiple-dose study in healthy subjects and a study in subjects with renal impairment) and Phase 2 data (a study in patients with complicated skin and skin structure infections [cSSSI]). CPT concentrations were simulated for 4000 subjects with normal renal function (creatinine clearance >80 mL/min) at a dose of 600 mg CPT q12 h IV administered over 1 h. Simulations were also performed for a 3-h infusion (same dose) to provide sustained plasma concentrations to achieve a high PTA. Accounting for variations anticipated in an actual patient population, the analysis assumed a 21% coefficient of variation (between-subject variability of clearance) derived from a population PK model that includes patients with cSSSI. The percentage of time (%T) of the dosing interval during which serum free drug concentration exceeded the minimum inhibitory concentration (MIC) was estimated for MIC values of 0.25, 0.5, 1, 2, 4, and 8 μg/mL. The %T>MIC was determined based on a free drug concentration of 80%.
Results: MC simulations of 600 mg CPT q12 h administered over 1 h demonstrated a mean %T>MIC of 51% (MIC=2 μg/mL). The simulated mean %T>MICs with the 3-h infusion were 59% (MIC=2 μg/mL) and 41% (MIC=4 μg/mL), respectively, as shown below.

Target MIC (μg/mL)	% T>MIC			
	1-h infusion		3-h infusion	
	Mean	LL 90% CI	Mean	LL 90% CI
0.25	98	86	99	95
0.5	89	67	94	77
1	71	51	78	60
2	51	38	59	46
4	34	25	41	31
8	18	11	20	7

CI = confidence interval; LL = lower limit.

Conclusions: Based on MC simulations in subjects with normal renal function, 600 mg CPT q12 h administered as either a 1-h or 3-h infusion will achieve a high PTA to be able to eradicate target pathogens at an MIC of 2 μg/mL. A 3-h infusion provides a modest increase in the %T>MIC and allows good coverage for the target of 4 μg/mL. Given relevant pathogen susceptibility profiles, epidemiological data, and animal PK/PD model data, both of these proposed dosing regimens will achieve a high PTA for target pathogens associated with relevant indications.

Antibiotic usage and abusage: the problems

P1267 Determinants of antibiotic use in surgical wards and in intensive care units in southwestern France

C. Dumartin, A.M. Rogues, B. Amadeo, A. Fourrier-Reglat, J.P. Gachie, P. Parneix (Bordeaux, FR)

Objective: To study factors associated with antibiotic (AB) consumption in surgical wards and in intensive care units (ICU) and their relevance for benchmarking, in the context of recent French guidelines promoting reporting of AB use to health authorities.
Method: Data were retrospectively recorded for the whole years 2002 and 2005 from a convenience sample (51 and 55 surgical wards with 1,105,232 and 991,506 PD, 35 and 31 ICU with 139,102 and 139,976 PD): consumption of AB for systemic use (defined daily doses per 1,000 patient-days: DDD/1,000 PD and per 100 admissions: DDD/100 AD), number of central-line per 1,000 PD (2005) and hospital characteristics (administrative type, length of stay (LOS), number of beds: total and for ICU and surgical wards). Additional data were obtained from nosocomial infection surveys for 13 ICU and 23 surgical wards. AB were classified according WHO recommendations (ATC-DDD system, 2005). Multiple linear regression was performed in a backward stepwise approach.
Results: Median AB consumption, expressed in DDD/1,000 PD and DDD/100 AD was 1186 and 621 in 2002 and 1416 and 932 in 2005 in ICU; 477 and 268 in 2002 and 505 and 237 in 2005 in surgical units. Administrative type of hospital was associated with total AB use in both areas with highest consumption in public hospitals. Pattern of AB use was associated with LOS in ICU: use of penicillins with betalactamase inhibitors (J01CR) was lower in ICU with higher LOS, use of glycopeptides (J01XA) was higher. Total AB use in ICU was linked with number of central-line per 1,000 PD in 2005. Surgical units in public and private hospitals had different patterns of consumption, with more first and second generation cephalosporins in private and more J01CR in public hospitals in 2005. No relationship was found between patient characteristics and AB use for the 23 surgical units providing data on patient case-mix.
Conclusion: Specific data on risk factors in ICU or surgery were difficult to collect and did not seem to be more linked with AB use than readily available characteristics such as type of hospital, LOS, number of beds and of admissions for each area, number of central-line. Therefore, these factors seem relevant as surrogate to reflect patients case-mix, and should be used for stratification when comparing AB consumption from various hospitals.

P1268 Predictors of piperacillin-resistant *Pseudomonas aeruginosa* among patients with respiratory tract infections: the predictive value of varying exposure definitions and the risk of multiple prior antibiotic exposures

N. Patel, T.P. Lodise (Albany, US)

Objectives: The primary objective was to determine if different prior antibiotic exposure (PAX) thresholds affected the likelihood of piperacillin-resistance (PR) among patients with *Pseudomonas aeruginosa* (PA) respiratory tract infections. The secondary objective was to examine the relationship between number of PAXs and PR-PA within the different PAX thresholds.
Methods: Retrospective cross-sectional study of patients with respiratory *P. aeruginosa* clinical cultures between 2001 and 2005. Demographics, co-morbid conditions, microbiology, and PAX data

were collected. Each of the following represents a unique PAX: piperacillin-tazobactam, cefepime, carbapenem, fluoroquinolone, and aminoglycoside. Two analyses were performed. In the first, the following PAX thresholds were examined: >24, >48 and >72 hours. Classification and Regression Tree (CART) analysis was also used to identify the PAX threshold for each drug class associated with an increased risk of PR-PA. Within each PAX threshold, log-binomial regression model was used to identify independent predictors of PR-PA. In the second analysis, patients were categorised by number of PAX (0, 1, 2 or >3) within each PAX threshold. Similar to the first analysis, log-binomial regression model was used to identify predictors of PR-PA within each PAX threshold.
Results: In the first analysis, prior piperacillin exposure was associated with PR-PA for each PAX threshold evaluated. The association between PR-PA and the other unique PAX varied according to the PAX threshold examined; more unique PAX were associated with PR-PA as the duration of PAX threshold increased in duration. In CART, carbapenems had the shortest duration of PAX associated with PR-PA (3 days), followed by fluoroquinolones (4 days), aminoglycosides (5 days), cefepime (9 days) and piperacillin/tazobactam (11 days). For the CART-derived PAX threshold log-binomial analysis, all classes were found to be associated with PR-PA, with the exception of carbapenem. In the second model, when the unique PAX were replaced by number of PAX, the number of PAX was independently associated with an increased risk of PR-PA at each threshold examined (table 1).

Log-binomial regression analysis of multiple prior antibiotic exposures associated with PR-PA

Covariate	Prevalence Ratio	95% CI	P-value
⩾24 hours			
Number of prior exposures	1.62	(1.31–2.00)	<0.001
⩾48 hours			
Number of prior exposures	1.56	(1.27–1.93)	<0.001
⩾72 hours			
Number of prior exposures	1.77	(1.42–2.20)	<0.001
CART breakpoints			
Number of prior exposures	2.17	(1.67–2.82)	<0.001

Conclusion: The results indicate that the antibiotic classes that predict PR-PA differ depending on the threshold of PAX utilised. The results also demonstrated that number of PAX, irrespective of class, was a more consistent and better predictor of PR-PA than unique PAXs.

P1269 Are we still using too many antibiotics for acute bronchitis?

F. Marra, M. Chong, D. Patrick (Vancouver, CA)

Background: Acute bronchitis is a lower respiratory tract infection that causes reversible bronchial inflammation. In up to 95 percent of cases, the cause is viral. While antibiotics are often prescribed for patients with acute bronchitis, little evidence shows that these agents provide significant symptomatic relief or shorten the course of the illness and may in fact lead to the emergence of resistant organisms. We undertook a study to evaluate the consumption of antibiotics for acute bronchitis in British Columbia (BC), Canada.
Methods: We obtained data from the BC PharmaNet database on all outpatient oral antibiotic prescriptions from 1996 to 2005. Prescriptions were expressed as their defined daily dose (DDD) per 1,000 inhabitants according to the 2006 World Health Organisation Anatomical Therapeutic Chemical system. This data was linked to the physician billing system to determine the reason for the antibiotic prescription. Overall and class-specific rates of consumption were described by year for treatment of acute bronchitis.
Results: In 1996, the BC consumption rate for all antibiotics used for acute bronchitis was 0.98 DDD per 1000 inhabitant-days. This decreased to a low of 0.63 DDD per 1000 inhabitant-days in 2002 but since then has increased such that in 2005, the rate was 0.81 DDD per 1000 inhabitant-days. Increases in fluoroquinolone use, specifically moxifloxacin (37-fold from year 2000 to year 2005), clarithromycin (3-fold) and azithromycin (7-fold) were seen while use of tetracyclines and B lactams declined by approximately 50%.
Conclusions: Physicians continue to prescribe antibiotics for acute bronchitis and we need to implement a multi-pronged approach within the province to change prescribing.

P1270 Antibiotic usage in Queensland public hospitals

L. Davis, D. Paterson, D. Olesen (Brisbane, AU)

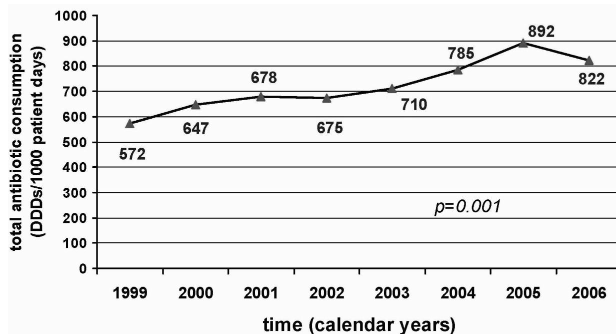
Objectives: In Queensland Australia, all the public hospital pharmacies use a common database for drug transactions. The aim was to regularly extract data from this database in order to obtain information about antibiotic consumption across Queensland Health facilities over time. This information will then be distributed back to pharmacists, infectious diseases physicians and microbiologists in order to inform formulary restrictions and influence clinical practice change in relation to antibiotic usage at the local hospital level.
Methods: Data of all antimicrobials transactions in the pharmacy database were extracted into a custom built application. Antibacterial agents were categorised using the Anatomical Therapeutic Chemical (ATC) classification index with 2007 defined daily doses (DDD). Antibiotic use was measured using DDD per 1,000 patient days (DDD/1000 PD). Data was stratified into intensive care (ICU) based on classification as a level 2 or 3 unit, and non ICU. Outpatient use was excluded as was data from the large tertiary paediatric facility and where it was possible to identify paediatric usage in the other facilities this data was also excluded.
Results: Total antibiotic consumption for Queensland public hospitals in 2006 was 946 DDD/1000 PD and in ICUs it was 657 DDD/PD. The β-lactam antibacterials, penicillin (ATC class J01C) accounted for just over half the total usage (481 DDD/1000PD) but only a third of the ICU usage (221 DDD/1000PD). The other β-lactam antibacterials (ATC class J01D) constituted 24% percent of the usage in ICU (156 DDD/1000PD) and 18% of the overall consumption (173 DDD/1000PD). Macrolides, lincosomides and streptogramins (ATC class J01F) accounted for 16% of the ICU antibiotic usage (107 DDD/1000PD) but only 9% of the total usage (89 DDD/1000PD).
Conclusion: Antibiotic usage in Queensland public hospitals is comparable with that reported nationally and in other Australian states. This consumption however, is higher than that reported in countries such as Denmark, Netherlands & Sweden. Regular and timely feedback of these antibiotic usage rates to those who have influence and control over prescribing and formulary restrictions within the public hospital system should assist to improve prescribing practices.

P1271 Trends in antibiotic consumption over an 8-year period in a general hospital of Athens, Greece

C. Loupa, I. Tzannou, V. Tsolaki, A. Dimizas, G. Psatheris, M. Panagou, M. Divani, M. Lelekis (Athens, GR)

Objective: The aim of the present study was to record the trends in antibiotic consumption in our 300-bed general hospital over an 8 year period.
Methods: Antibiotic consumption for the period 1999 to 2006 was studied retrospectively using data from the pharmacy computer. Antibiotic use was calculated in DDDs per 1000 patient days (ABC Calc 3.0). We used linear regression for statistical analysis (SPSS 11.5).
Results: Antibiotic consumption was 572, 647, 678, 675, 710, 785, 892 and 822 DDDs/1000 patient days (years 1999, 2000, 2001, 2002, 2003, 2004, 2005 and 2006 respectively) and the trend was significant ($p=0.001$). Concerning consumption of major classes of antibiotics, only penicillins had a decrease (from 83.4 to 55.6 DDDs per 1000 patient days). The consumption of other classes of antibiotics had

the following trend over time: cephalosporins/aztreonam from 152.6 to 217 (p=NS), penicillins+inhibitors from 133.9 to 210.9 ($p = 0.028$), carbapenems from 3.8 to 18 ($p = 0.005$), aminoglycosides from 45.4 to 35.2 (p=NS), macrolides from 35.9 to 68.2 (p=NS), quinolones from 28.6 to 109.6 ($p < 0.001$) and glycopeptides from 1.3 to 22.7 DDDs per 1000 patient days ($p = 0.002$). It is worth noting that carbapenems, quinolones and glycopeptides are included in the restricted antibiotics list for all Hellenic hospitals since late ’80s, together with 3rd-4th generation cephalosporins/monobactams.



Conclusions: During the study period, total consumption increased significantly and this was the case for almost all major classes of antibiotics as well, including ones under restriction. Future studies will reveal if the decrease of total consumption recorded in 2006 compared to 2005 is incidental or is the beginning of a downwards move of the consumption. Meanwhile, due to the incremental trend of total and restricted antibiotics consumption, it is quite obvious that our restriction policy is unsuccessful and should be revised.

P1272 Demographic factors associated with increase in antibiotic consumption in Danish primary healthcare

U.S. Jensen, S.S. Olsen, A.M. Hammerum, N. Frimodt-Møller (Copenhagen, DK)

Objectives: From 1997 to 2006 an increase of 24% in total antibiotic consumption in Danish pri-mary healthcare has been observed. The aim was to compare and possibly associate various demo-graphic factors with the increase in antibiotic consumption.
Methods: Data were obtained from the DANMAP 2006 report, the Danish Medicines Agency, the National Board of Health and the Statistics Denmark.
Results: The antibiotic consumption varied between the 15 Danish counties; however the increase was parallel in all counties throughout the study period. From 2000–2006 the increase in number treated/1000 inhab./days was 6% for both women and men. A significantly higher proportion of women received antibiotics (358/1000 inhab.) compared to the proportion of men (261/1000 in-hab.). People of both gender aged >70 years received 1.6 times more antibiotics than people <70 years of age.
The distribution by sex in the population did not change throughout the study period.
From 1997 to 2006 the population has increased by 145,000 inhabitants to a total of 5.4 million. The major part of this increase was in the age group; 60–69 years of age (~125,000). An estimated extra antibiotic consumption of these additional 125,000 people would only increase the total use of antibiotics in 2006 by 4%. From 1997 to 2006 the overall number of contacts with primary healthcare – which can be used as a general measure of the activity in primary healthcare – increased 38% for women and 32% for men.
During the period the major relative increase in consumption of individual antibiotic groups was in β-lactamase resistant penicillins (209%) and β-lactam-inhibitor combinations (500%), but these groups only constituted 6.9 and 0.8% of the total use, respectively. The consumption of the largest group, β-lactamase sensitive penicillins representing 35% of the total consumption in primary healthcare throughout the entire study period, increased 18%.
Conclusion: The 24% increase in total antibiotic use from 1997 to 2006 in Denmark was parallel in all counties and parallel for women and men at all age groups. While the total population increased only slightly, a 32–38% increase in contacts with primary healthcare was observed during the pe-riod. The overall increase encompassed most antimicrobial groups. Apparently, the recent increase in antibiotic consumption in Denmark is due to general socio-health factors with no easy single tar-gets for intervention.

P1273 The intravenous route in hospital patients – Is this being misused?

A. George, M. George, S. McKain, K. Shute, K. Swarnkar, I. Grant, D. Defriend, P. Turner (Newport, Plymouth, Torquay, UK)

Aims: It is assumed that almost every patient who is admitted to hospital will have a peripheral cannula inserted. It is observed that patients receive intravenous therapy long after resuming a normal gut function. The aim of this study was to assess if intravenous therapy could be terminated sooner thereby avoiding the associated costs and increased patient morbidity
Methods: 200 randomly selected medical and surgical hospital in-patients across three NHS Trusts in Southern England who had a peripheral venous cannulae inserted for intravenous therapy were monitored daily for 8 days or until removal of the cannula – whichever came first. A non-interventional study was undertaken by gathering information on all aspects of intravenous therapy including intravenous fluids and antibiotics that the patient received. The ability of the patient to take a normal diet was also checked – this signifying that the patient had a normally functioning gut, which could absorb oral fluids and medicines, whereby, use of the intravenous route could have been avoided.
Results: 74% of cannulae continued to be used in patients to give intravenous fluids and antibiotics inspite of the patient being on a normal diet. 40% of the cannulae were left in for more than 48 hours after their use had stopped with a minority being left in for more than 120 hours. The tendency for healthcare personnel to continue patients on intravenous fluids and medication in spite of the patient on a normal diet was largely attributed to the lack of awareness among the healthcare personnel
Discussion: This study highlights an urgent need to increase the awareness among the healthcare personnel. The ability of a patient to fully absorb oral medications while on a normal diet is being stressed along with the need to increase oral fluid intake of the patient instead of continuing on intravenous fluids. Though peripheral cannulae are essential in patients, their use should be regulated and carefully monitored.
Peripheral intravenous cannulation is an innocuous procedure but has a potential for significant morbidity and increased healthcare costs. The use beyond necessity remains singularly unrecognised. Attention to detail and continuing education of the healthcare personnel is all important.

P1274 Factors affecting achievement of antimicrobial prescribing targets in general practice

M. Heginbothom (Cardiff, UK)

Objectives: During the last decade, the emergence and spread of antimicrobial resistance has become a major global healthcare concern. There is a plethora of evidence showing that antimicrobial consumption is the major factor driving resistance and a number of intervention programmes have been initiated internationally. Of central importance to these programmes are measures to reduce inappropriate antimicrobial use. Following government recommendations to facilitate reduced prescribing, in 2001, the health authorities in Wales introduced antimicrobial prescribing indicator targets as part of a general practitioner (GP) prescribing incentive scheme. The aim of this study is

to investigate factors affecting achievement of antimicrobial prescribing targets by GPs in Wales.

Methods: 480 general practices comprising 1785 GPs based in Wales were included in this cross-sectional study. Antimicrobial prescribing analysis and cost (PACT) data for 2001 was scored against the prescribing indicator targets for the year (see table). A score of zero was interpreted as 'failing to achieve' the target. Logistic regression modelling was used to explore the relationship between outcome and possible explanatory variables including age or gender of GP, contracted hours, place of qualification, number of GPs in practice, list size (patients per GP), deprivation index (Townsend score), dispensing practice, morbidity data, and practice training status.

Results: Overall, the percentages of practices failing to meet Target 1 (winter), Target 1 (summer), Target 2, and Target 3 were 14.6, 8.5, 11.9, and 45.8 respectively. Practices that failed to achieve Target 1 (winter) were situated in areas of high-deprivation where practitioners were single-handed, not-qualified in the UK and near retirement ($p < 0.001$). However, for the summer quarters failure was associated with training practices in areas of low-deprivation ($p < 0.05$). Failure in both Targets 2 & 3 was most strongly associated with dispensing practices ($p < 0.05$).

Conclusions: The factors associated with failing to achieve the targets are complex with different practice profiles for those failing summer and winter targets. This may relate to the nature of the targets which suggests that great care should be taken in target design. The financial incentives associated with being a dispensing practice appear to skew the prescribing practices of GPs to increased use of fluoroquinolones and less use of narrow spectrum agents.

P1275 Trends in antibiotic prescription among children attending daycare centres in France: 1999–2006

C. Van Dijken, P. Bruno, P. Touboul, H. Carsenti-Dellamonica, M. Roussel-Delvallez, M. Lelieur-Piérard, B. Dunais, C. Pradier, P. Dellamonica (Nice, Lille, FR)

Objectives: to assess trends in antibiotic prescription among children attending day-care centres (DCC) following promotion of prudent antibiotic use (PAU) in uncomplicated paediatric respiratory tract infections (RTI).

Methods: antibiotic prescriptions were recorded from health booklets over a 3-month period preceding each of 4 pneumococcal nasopharyngeal carriage surveys among a random sample of children from January-March 1999, 2002, 2004, 2006 in DCCs in the Nord (ND) and Alpes Maritimes (AM) areas. A local intervention promoting PAU in paediatric RTI was conducted in AM in 2000 and 2003, via academic detailing visits to all general practitioners and paediatricians, and a national media campaign began in 2002. Number of treated episodes and distribution of diagnoses were studied for each survey in both areas.

Table 1: Trends in proportion of treated children

Year	N	% treated	OR	95% CI	p
Alpes Maritimes					
1999	221	59.30%	1		
2002	209	48.80%	0.65	0.44, 0.98	0.03
2004	258	48.80%	0.66	0.45, 0.96	0.02
2006	283	25.40%	0.23	0.16, 0.35	$<10^{-3}$
Nord					
1999	226	74.80%	1		
2002	177	65.50%	0.64	0.41, 1.01	0.04
2004	171	55.00%	0.41	0.26, 0.64	$<10^{-3}$
2006	227	50.20%	0.34	0.022, 0.52	$<10^{-3}$

Results: The proportion of treated children fell significantly over the study period (Table 1), as did the average number of treated infections/child, from 1.00±0.07 to 0.33±0.65 in 2006 in AM and from 1.57±1.26 to 0.84±1.09 in ND between 1999 and 2006, respectively ($p < 10^{-5}$ for each area). Among documented diagnoses, the proportion of prescriptions for rhinopharyngitis decreased from 15.1% to 6.5% in AM ($p = 0.08$) and from 24.4% to 13.7% in ND ($p = 0.06$), while that for acute otitis media increased from 34.2% (N=193) to 45.7% (N=81) in AM ($p = 0.07$) and from 31.6% (N=291) to 53.6% (N=168) in ND ($p < 10^{-5}$) between 1999 and 2006, respectively.

Distribution of antibiotic classes between 1999 and 2006 shifted towards 3rd generation cephalosporins from 25.8% of prescriptions (N=217) to. 37.5%(N=104) in AM ($p = 0.03$) and from 19.0%(N=358) to. 40.8%(N=191) in ND($p < 10^{-5}$), respectively, at the expense of 1st generation cephalosporins and macrolides.

Conclusion: Interventions advising PAU proved effective in RTI management among children attending DCCs. Fewer children were treated and rhinopharyngitis accounted for a lower proportion of prescriptions after the interventions. However, increasing use of wide spectrum antibiotics may hamper efforts to curb bacterial resistance.

P1276 Role of different classes of antimicrobials on the risk of acquisition of resistant micro-organisms in critically ill medical patients

J.A. Martínez, J. Vila, E. Delgado, M.R. Monte, A. Alquezar, P. Castro, A. Trilla, C. Codina, P. Vaselka, J.M. Nicolás (Barcelona, ES)

Objective: To assess the role of different classes of antibiotics on the risk of acquisition of resistant micro-organisms in critically ill medical patients.

Methods: From March 2006 to May 2007, all patients admitted to an 8-bed medical intensive care unit (MICU) were subjected to swabbing of nares, pharynx and rectum, and culture of respiratory secretions on admission and thrice weekly thereafter. Acquisition of a resistant microorganism was defined as the isolation, after 48 hours of MICU stay, of a strain of meticillin-resistant *Staphylococcus aureus*, vancomycin-resistant enterococci, enteric Gram-negative bacilli resistant to third-generation cephalosporins, *Pseudomonas aeruginosa* resistant to at least one class of antipseudomonals or any other non-fermenter from patients whose admission cultures were either negative or positive for a susceptible isolate of the same species. The first acquired resistant microorganism defined the outcome. Recorded clinical variables included demographics, severity scores, underlying conditions and exposure to any procedure or drugs during MICU stay. Analysis was restricted to patients with a length of stay greater than 2 days and performed by using a logistic regression procedure.

Results: Out of 293 patients evaluated, 72 (25%) acquired a resistant microorganism, including a Gram-positive in 8 (3%), *P. aeruginosa* in 19 (6%), other non-fermenters in 12 (4%), *Escherichia coli* in 16 (5%), *Klebsiella* spp. in 6 (2%), and an enteric ampC-bearing organism in 11 (4%). The primary site of colonisation involved the rectum in 57 cases (79%). Of 270 (92%) patients exposed to antimicrobials, 204 (76%) received an antipseudomonal regimen, including ceftazidime in 33 (12%), piperacillin-tazobactam in 62 (23%), meropenem in 93 (34%) and a quinolone in 106 (39%, ciprofloxacin in 33 and levofloxacin in 73). Multivariate analysis selected age (OR 1.02, 95% CI 1–1.04), use of ceftazidime for >3 d (OR 3.8, 95% CI 1.3–11), mechanical ventilation for >3 d (OR 7.9, 95% CI 2–31) and exposure to a nasogastric tube (OR 15, 95% CI 2.8–79) as the best predictors for the acquisition of resistant organisms, whereas location in two particular rooms was protective (OR 0.3, 95% CI 0.1–0.8).

Conclusions: Currently, in critical care settings characterised by an almost universal exposure to antimicrobials, ceftazidime use may represent the antimicrobial exposure associated with the highest risk for the acquisition of resistant bacteria.

P1277 Pharmaceutical quality and supply route of antibiotics obtained with or without prescription (over the counter) in Indonesia

U. Hadi, P.J. van den Broek, M. Keuter, E. Kolopaking, W. Gardjito, I.C. Gyssens (Surabaya, ID; Leiden, Nijmegen, NL)

Background: Our survey of 2996 individuals visiting public healthcare facilities in Indonesia showed that 17% of antibiotic users obtained the antibiotics over the counter (OTC) from different suppliers. Use of amoxicillin, ampicillin, chloramphenicol, ciprofloxacin, cotrimoxazole and tetracycline was most frequently reported.

Objective: To determine the supply route and the pharmaceutical quality (PQ) of frequently used oral antibiotics outside hospitals.

Methods: Four simulated clients requested antibiotics in 3 areas surrounding a government hospital and 2 healthcare centres in Surabaya. Clients went in 4 directions to visit each supplier on their journey in order to purchase 20 samples of 5 antibiotics. Sampling was equally divided over the different areas and suppliers. Samples were photographed, including package. PQ of tablets and capsules was analysed by a certified independent Dutch laboratory using HPLC.

Results: 75 pharmacies, 10 drugstores and 40 roadside stalls (kiosks) were visited. 104 samples were obtained, 76% without prescription and 81% generic. All but one out of 14 manufacturers were Indonesian. Never was oral information provided. Written information was limited to a copy of the dosing regimen from the prescription. Although “by doctor’s prescription only” was printed on all blisters, none of the OTC requests were refused nor questioned. Only one drugstore sold antibiotics (tetracycline); 29 kiosks sold either amoxicillin, chloramphenicol, ciprofloxacin or tetracycline. The PQ of 23 chloramphenicol and 19 ciprofloxacin samples were within British Pharmacopeia (BP) limits. The content of 5/20 amoxicillin and 5/22 tetracycline samples were <5% below BP limits, but in 10/20 of cotrimoxazole tablets, trimethoprim was 20% below BP limits, 8/9 of which from the same manufacturer. There was no difference of PQ between suppliers, between generic and branded samples, or between blister-packed and unpackaged (plastic bag) samples. Prices of antibiotics from the same manufacturers were invariably higher in kiosks than in pharmacies; prices per tablet/capsule varied up to 6 fold for cotrimoxazole to 20 fold for ciprofloxacin.

Conclusion: Substandard quality is probably a manufacturing problem. Although in Indonesia OTC sales of antibiotics are prohibited by law, antibiotics were sold OTC in pharmacies and some were retailed at higher prices in kiosks. Enforcement of legislation is urgently needed.

P1278 The effect of antimicrobial use on resistance in *Escherichia coli* in Finland

M. Bergman, S. Nyberg, P. Huovinen, A.J. Hakanen and the Finnish Study Group for Antimicrobial Resistance (FiRe Network)

Objectives: The connection between regional antimicrobial resistance rates in *Escherichia coli* and regional outpatient antimicrobial use in Finland was investigated.

Methods: During a 9-year study period of 1997–2005, more than 700 000 *E. coli* isolates, mainly from urine samples, were tested for antimicrobial resistance in 26 microbiological laboratories, representing 18 of the 20 central hospital districts in Finland. The following antimicrobials were included in the study: amoxicillin, amoxicillin-clavulanate, first-generation cephalosporins (mainly cephalexin), fluoroquinolones (of which levofloxacin, norfloxacin, and ciprofloxacin were studied separately), trimethoprim, sulfatrimethoprim, pivmecillinam, and nitrofurantoin (Table). There were two study approaches: (1) the level of antimicrobial use of one year was compared with the level of resistance of the next year, and (2) the change in antimicrobial use was compared with the change in resistance within the study period.

Results: The following significant associations were found between the level of use and the level of resistance (approach No. 1): nitrofurantoin use vs. nitrofurantoin resistance, cephalosporin use vs. nitrofurantoin resistance, amoxicillin use vs. fluoroquinolone resistance, fluoroquinolone use vs. ampicillin resistance. The following significant associations were found between the change in use and change in resistance (approach No. 2): amoxicillin or amoxicillin-clavulanate use vs. ampicillin resistance, combined use of trimethoprim and sulfatrimethoprim vs. trimethoprim and sulfatrimethoprim resistance, and trimethoprim use vs. sulfatrimethoprim resistance. No other positive connections were found (Table).

Level of resistance and consumption			Change in resistance and consumption		
Resistance		Consumption	Resistance		Consumption
Ampicillin	vs.	Amoxicillin	Ampicillin	vs.	**Amoxicillin**
		Amoxicillin + Clavulanate			**Amoxicillin + Clavulanate**
		Fluoroquinolones			Fluoroquinolones
Cephalothin	vs.	Cephalosporins	Cephalothin	vs.	Cephalosporins
		Fluoroquinolones			Fluoroquinolones
		Trimethoprim			Trimethoprim
		Sulfatimethoprim			Sulfatimethoprim
		Trimethoprim + Sulfatrimethoprim			Trimethoprim + Sulfatrimethoprim
		Nitrofurantoin			Nitrofurantoin
Fluoroquinolones	vs.	**Amoxicillin**	Fluoroquinolones	vs.	Amoxicillin
		Amoxicillin + Clavulanate			Amoxicillin + Clavulanate
		Cephalosporins			Cephalosporins
		All fluoroquinolones			All fluoroquinolones
		Levofloxacin			Levofloxacin
		Norfloxacin			Norfloxacin
		Ciprofloxacin			Ciprofloxacin
Trimethoprim	vs.	Trimethoprim	Trimethoprim	vs.	Trimethoprim
		Sulfatrimethoprim			Sulfatrimethoprim
		Trimethoprim + Sulfatrimethoprim			**Trimethoprim + Sulfatrimethoprim**
Sulfatrimethoprim	vs.	Trimethoprim	Sulfatrimethoprim	vs.	**Trimethoprim**
		Sulfatrimethoprim			Sulfatrimethoprim
		Trimethoprim + Sulfatrimethoprim			**Trimethoprim + Sulfatrimethoprim**
Mecillinam	vs.	Pivmecillinam	Mecillinam	vs.	Pivmecillinam
Nitrofurantoin	vs.	**Cephalosporins**	Nitrofurantoin	vs.	Cephalosporins
		Nitrofurantoin			Nitrofurantoin

Conclusion: Because of the link between nitrofurantoin consumption and resistance, more attention should be paid to the prescription of nitrofurantoin for outpatient *E. coli* infections. An interesting cross-connection seems to exist between amoxicillin use vs. fluoroquinolone resistance and fluoroquinolone use vs. ampicillin resistance. Interestingly, a connection was not found between fluoroquinolone use and fluoroquinolone resistance.

P1279 Relationship between antimicrobial use and antimicrobial resistance in *E. coli* and *Klebsiella pneumoniae* blood isolates at 5 tertiary hospitals in Korea

H-H. Chang, S-I. Jung, S-W. Kim, Y.S. Kim, H.K. Ki, J.S. Yeom, K.S. Ko, D.R. Chung, K.R. Peck, J-H. Song on behalf of the KONSID (Korean Network of Studies on Infectious Diseases)

Objectives: Increases in the prevalence of antibiotic-resistant Gram-negative bacilli (GNB) in hospitals are frequently related to the high selective pressure of antibiotics. This study was performed to evaluate the association between antimicrobial resistance in *E. coli* & *Klebsiella pneumoniae* that caused bacteraemia in hospitalised patients and anti-GNB antimicrobial use in 5 tertiary teaching hospitals in Korea.

Methods: Data on annual patient-days and consumption (defined daily dose (DDD) per 100 patient-days) of antibiotics from January 2005 to December 2005 in 5 tertiary hospitals in various regions of Korea were analysed. A total 302 nonduplicate *E. coli* & *K. pneumoniae* isolates that caused nosocomial bacteraemia was collected from July 2006 to November 2006. To determine the antimicrobial resistance, broth microdilution test and double disk synergy were performed according to the CLSI performance standards. Spearman’s correlation coeffient was used to determine the relationship between antibiotic consumption and resistance.

Results: The prescription of anti-GNB antibiotics in 5 tertiary hospitals markedly varied (median value 93.04 DDD/ 100 patients-days, range 34.81–117.78 DDD/ 100 patients-days). Ceftazidime-resistant *E. coli*

& *K. pneumoniae* was significantly correlated with the higher use of aminopenicillins (r=0.900, $P<0.05$), total aminoglycosides (r=0.900, $P<0.05$), and carbapenems (r=0.900, $P<0.05$). Cefotaxime resistance showed positive correlation with the higher use of aminopenicillins and ceftazidime, but had no statistical significance (r=0.718, $P>0.05$ and r=0.600, $P>0.05$, respectively). Imipenem resistance showed week positive correlation with the higher use of carbapenems, but had no statistical significance (r=0.671, $P>0.05$).
Conclusion: The higher consumption of some antibiotics was significantly correlated with the higher rate of antibiotic-resistant *E. coli* & *K. pneumoniae*. Continuous surveillance of antibiotic use is needed to encourage appropriate prescribing of antibiotics and to reduce antibiotic resistance.

P1280 Junior doctors' perceptions of the problem of bacterial resistance in hospitals

C. Pulcini, F. Williams, P. Davey, D. Nathwani (Nice, FR; Dundee, UK)

Objectives: The aim of this study was to assess how the problem of bacterial resistance was perceived by the junior doctors.
Methods: We surveyed 63 junior doctors in their first year of postgraduate training at one university teaching hospital in Dundee (Scotland, UK) to assess their attitudes about the importance of antibiotic resistance, knowledge of its prevalence, beliefs about its causes and attitudes about interventions designed to address the problem.
Results: The response rate was 70% (63 of 90 doctors). Thirty-five (56%) junior doctors were training in a medical speciality and 24 (38%) in a surgical one. Sixty-two (98%) of them had prescribed an antibiotic within the past 6 months. Antibiotic resistance was perceived as a national problem by 92% of the respondents, but only 52% rated the problem as important in their own daily practice. Only 22% of the junior doctors had a correct idea of the prevalence of MRSA in UK hospitals. Nearly all doctors (94%) believed that widespread and inappropriate antibiotic use, or prescription of broad spectrum antibiotics were important causes of resistance. Excessive durations of antibiotic treatments were rated as an important cause of resistance by 80% of the doctors, but only 51% recognised too low antibiotic doses as a potential cause of bacterial resistance. Finally, only 45% of the doctors identified poor hand hygiene practices as an important driver for resistance. More than 90% of the junior doctors rated the following measures as helpful to improve antibiotic prescribing: educational sessions, availability of guidelines and readily accessible advice from a microbiologist/an Infectious Diseases specialist/a pharmacist/or a colleague. Regular audit and feedback of the antibiotic prescribing practices on the ward was found helpful by 82% of the doctors and availability of resistance data was rated useful by 77% of them. Restrictive measures were not as popular, with 66% of the junior doctors rating restriction of some antibiotics useful, and 13% finding the restriction of all antibiotics potentially helpful.
Conclusion: Although most junior doctors view antibiotic resistance as a serious national problem, perceptions about its local importance, its causes, and possible solutions vary more widely and are not always evidence-based. These perceptions must be taken into account to maximise adherence of the junior doctors to the measures aiming at curbing bacterial resistance.

P1281 Outpatient utilisation of antibiotics in Zagreb, 2006

D. Štimac, J. Culig, D. Jonjic, Z. Šostar, M. Bucalic (Zagreb, HR)

Objectives: Antibiotics accounted for 4% of total prescription drug utilisation in 2006, expressed as DDD/TID, and for 10% of financial drug utilisation. The aim of the study was to assess antibiotic utilisation in 2006 in the City of Zagreb.
Methods: Data on the number of packages for each individual drug were collected from all Zagreb Pharmacy units. Based on these data, the number of defined daily doses(DDD)and DDD/1000inhabitants/day(DDD/TID)for 2006 were calculated for all 14 drug groups of the Anatomical-Therapeutic-Chemical (ATC) drug classification system at all levels of ATC system for each individual drug.
Results: Total outpatient utilisation of antibiotics in Zagreb was 37.38DDD/TID, with penicillins accounting for 50%.The subgroup of penicillin combinations yielded a 54% share in the utilisation of antibiotics, and referred completely to amoxicillin + clavulanic acid combination, for years the most frequently prescribed antibiotic in Zagreb. The subgroup of penicillins sensitive to β-lactamases, accounted for 23% of penicillin utilisation. The subgroup of broad-spectrum penicillins, accounted for 21.50% of penicillin utilisation. The majority of this subgroup utilisation referred to amoxicillin with 3.96 DDD/TID. The subgroup of β-lactamase resistant penicillins showed lowest share in the overall antibiotic utilisation. Cephalosporins accounted for 20.5% of total antibiotic utilisation. Cefuroximeaxetil accounted for the most part of utilisation with 5.5DDD/TID, followed by cephalexin with 1.44DDD/TID. In the J01E subgroup, sulfamethoxazole+trimethoprim accounted for the entire utilisation with1.39DDD/TID.The utilisation of macrolides was 4.04 DDD/TID.Aminoglycosides showed a utilisation of 0.15DDD/TID.Tetracyclines accounted for 7%, and quinolones, for 6% of antibiotic utilisation in Zagreb. Norfloxacin accounted for 70% of utilisation in this group. In the group of other antimicrobials, nitrofurantoin accounted for almost entire outpatient utilisation with 0.90 DDD/TID.
Conclusion: Almost one-third of outpatient antibiotic utilisation in the City of Zagreb in 2006 referred to amoxicillin+clavulanic acid, whereas current guidelines suggest that narrow-spectrum antibiotics should be preferred. Therefore, the utilisation of antibiotics in the City of Zagreb could not be considered appropriate.

Antibiotic usage and abusage: the solutions

P1282 Results after the introduction of a pharmacist-managed surgical antibiotic use policy

M. Szabo, S. Abraham, R. Benko, M. Matuz, E. Hajdu, G. Lazar (Szeged, HU)

Objectives: Our study aims at comparing the use of surgical antibiotics before and after the introduction of local surgical antibiotic use policy.
Methods: The research was performed at an 82-bed General Surgery Department. The local surgical antibiotic use policy was launched by the pharmacy service in December 2005. We analysed the surgery-related antibiotic use in the February months the preceding (2004–2005: Period I) and in the subsequent two years (2006–2007: Period II). In order to determine individual antibiotic usage, data were collected retrospectively from flow-charts and anaesthetic records. Surgical procedures were classified according to wound class categories. The following parameters were compared: the frequency of antibiotic use in different wound class categories, the timing of antibiotic administration, the duration and the average price of antibiotic use.
Results: 822 operations were performed (438 in period I; 384 in period II). In terms of wound class, antibiotics were administered in the following proportions: 30.3% vs. 44.8% clean, 54.2% vs. 50.0% clean-contaminated, 41.3% vs. 60.3% contaminated, and 86.2% vs. 83.3% infected surgeries. The most frequently used antibiotics was cefuroxime (or cefuroxime-metronidazole combination) in both periods. Concerning proper timing, Period I saw antibiotics administered in the morning, disregarding whether the patient was operated immediately afterwards or only later during the day. In period II antibiotics were administered in the operating theatre in all instances, concurrently with the induction of anaesthesia. The average duration of the surgery-related antibiotic use was 3.3±2.0 days in period I, vs. 2.4±2.0 days in period II. Calculating with prices valid in 2007, the average price of surgery-related antibiotic use has decreased from 18.3±5 to 9.0±2 Euro.
Conclusion: The introduction of the local surgery-related antibiotic use policy was successful in several aspects, since proper timing, shorter duration of prophylactic antibiotic use and cost savings were achieved. However, patient-level analysis highlighted fields of inappropriateness:

despite the fact that prophylactic or therapeutic antibiotic use would be in several cases the surgeons did not indicate antibiotic use. Therefore, we demonstrated that the initiations of the pharmacy service and the continuous evaluation of its effectiveness are both essential in order to improve surgery-related antibiotic use.

P1283 Implementation of an intravenous to oral switch policy for antimicrobials in a secondary care setting

K. Dunn, A. O'Reilly, V. Treacy, T. Rogers, C. Bergin (Dublin, IE)

Objectives: Sequential therapy is defined as the timely transition from parenteral to oral antimicrobial therapy. It is promoted as intravenous therapy is more expensive, has significant adverse effects, is time consuming for staff and is not always more efficacious.
To develop and issue guidelines to clinical pharmacists on enacting an intravenous to oral switch policy in a large Irish teaching hospital.
To implement an intravenous to oral switch policy, and to examine the effect of this policy.
To find out if an earlier switch to an oral antimicrobial resulted in a shorter hospital stay.
To record where empiric treatment was prescribed, if the initial antimicrobial chosen complied with the hospital empiric guidelines.
To calculate cost savings generated from the implementation of the stategy.
Methodology: This was a prospective, controlled before and after study. A control and study group were included. The intervention consisted of the application to the drug chart of stickers promoting an oral switch along with a guide on the criteria for switch. Duration of intravenous treatment, the number of days after the criteria were met before antimicrobials were switched to oral, length of stay and cost savings were measured. Compliance with the hospital empiric antimicrobial guidelines was assessed.
Results: The study included 236 patients prescribed 289 intravenous antimicrobial courses. The duration of intravenous treatment reduced significantly between the pre- and post-intervention periods, when comparing the study group to the control group ($p = 0.02$). The number of days after the criteria for switching was met before the patient was switched to oral antimicrobials reduced significantly post-intervention in the study group compared to the control group ($p = 0.017$). The median length of stay did not reduce. The intervention was cost effective, and resulted in some cost savings, (€6.41 per patient in the post-intervention study group). 88.8% of prescriptions were concordant with the empiric antimicrobial prescribing guidelines.
Conclusions: Implementation of the strategy resulted in a reduced duration of intravenous antimicrobial treatment, with resulting cost savings. There was no reduction in the median length of stay, likely due to social reasons and other co-morbidities lengthening stay. This strategy is to be rolled out to all general medical and surgical wards in the hospital.

P1284 The Going Home project: implementing a frontline pharmacist-led team approach towards appropriate IV to oral antibiotic switch for patients with antibiotic resistant infections and subsequent discharge to outpatient management

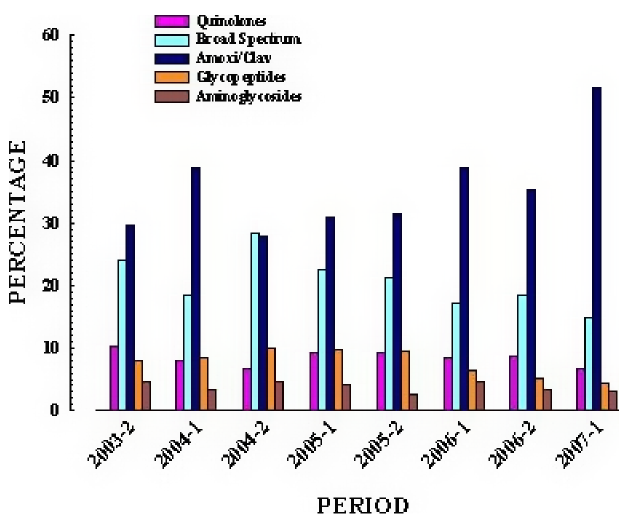
K. Bamford, M. Desai, W. Lawson, A. Jacklin, F. Sanderson, A. Holmes, M. Brown, B. Dean Franklin (London, UK)

Objectives: A previous study showed that 29% of patient on IV glycopeptides, predominantly used to treat proven or suspected MRSA, fulfilled clinical criteria for switch to oral antibiotics and discharge to completer treatment as an outpatient with a median reduction in stay of 5 days. Prior to this study there was no IV-oral switch program for glycopeptide use with patients usually remaining in hospital until the end of treatment. The objectives of this work were to assess whether the predicted benefit of earlier appropriate discharge to home treatment could be implemented by targeting this group of patients, and if so, whether this was an effective management strategy.
Methods used: We implemented a study using the same approach. All patients on IV glycopeptides were screened against pre-determined IV-oral switch and discharge on oral antibiotics criteria. The study team identified patients suitable for IV-oral switch and discharge. Advice was provided to prescribers on the most appropriate oral antibiotic for switch and treatment at home. Follow up was arranged as appropriate to clinical need.
Switch from IV glycopeptides to oral suitable antibiotics, reduction in length of stay, IV line use, and estimated cost savings were measured. In addition pharmacist time and interventions profile was assessed.
Results: 81 (52%) of patients on IV glycopeptides were switched to an oral antibiotic. 64 (41%) were discharged home early on oral antibiotics. 22 different combinations of oral antibiotic that were either consistent with trust policy or specifically approved by senior microbiology/infectious diseases specialists were used. Overall this intervention resulted in a reduction of 1215 bed days and a further 511 in-patient IV line days. The study ran in parallel and was complimentary to the introduction of an OPAT service.
Conclusion: A targeted approach by a dedicated team results in a significant reduction in hospital length of stay for patients being treated for resistant Gram-positive infections with IV glycopeptides. This intervention improves the quality of infection management and resource utilisation. This has resulted in a successful business case for an enhanced antibiotic pharmacist team.

P1285 Unexpected impact of infectious diseases division interventions on antibiotic use in two intensive care units

S. Cherifi, J. Massaut, G. Mascart, S. Jamart, R. Karmali (Brussels, BE)

Objectives: The purpose of the present study was to estimate the impact of infectious diseases division interventions on the antibiotic use in two intensive care units (ICU) (12 beds of medical intensive care (MIC) and 12 beds of surgical intensive care (SIC) in a Belgium University hospital between 2003 and 2007.
Methods: One infectious diseases specialist with one microbiologist specialist constituted the infectious disease division and their main goals were twofold: 1) a reduction in the amount of broad spectrum antibiotics (including 3rd generation cephalosporins, cefepim, meropenem, aztreonam and piperacillin/tazobactam), fluoroquinolones, glycopeptides and aminoglycosides administered; 2) a cutback on the length of empirical treatment. The interventions started in 2005 with quality rounds (twice a week).
Antibiotic consumption data were obtained from the pharmacy and expressed as the number of DDDs (Daily Dose Defined) per 100 bed days.



Results: The interventions of the infectious diseases division resulted in an increase of total antibiotic consumption in SIC from 224 DDDs/100

bed days in 2005 to 281 in 2007 whereas a decrease from 492 to 334 DDDs was observed in MIC during the same period. In both intensive care units, the use of amoxicillin/clavulanic acid increased, particularly in SIC from 65 to 139 DDDs, while the proportion of broad spectrum antibiotics given decreased significantly. Aminoglycosides remained stable in both ICU whereas glycopeptides and fluroquinolones decreased in MIC.

Conclusions: The overall antibiotic consumption in SIC increased dramatically due to a progressive evolution towards a polyvalent intensive care with a mixture of surgical and medical pathologies. The pressure exerted by the intervention division on the ICU physicians led to a decrease use in broad spectrum antibiotics but at the expense of a spectacular increase in the consumption of amoxicillin/clavulanic acid. These preliminary data encouraged us to continue the collaboration with intensive care physicians and should prompt us to think on the real need of antibiotic therapy even in the ICU setting.

P1286 Checklist for an optimal early switch to oral antibiotics in hospitalised patients

D. Mertz, M. Koller, P. Haller, M.L. Lampert, H. Plagge, G. Koch, M. Battegay, U. Fluckiger, S. Bassetti (Basel, CH)

Background: Several studies have evaluated early switch criteria from intravenous (IV) to oral antibiotic therapy in restricted patient populations, e.g. with community-acquired pneumonia. Only few reliable data are available about using switch criteria in general medicine wards.

Objectives: To evaluate the effect of a checklist for early switch from IV to oral antibiotics in general medicine wards on duration of IV antibiotic therapy, safety and costs.

Methods: The study was performed in general medicine wards with 2500 admissions annually in a university hospital. All patients on IV antibiotics were enrolled. A checklist with 10 switch criteria such as defined diagnoses, clinical improvement with defined defervescence and oral suitability of antibiotics was placed in the charts. We analysed the checklists of the entire study-year (8/06 to 7/07) providing information about reasons against oral switch and safety aspects (n = 398). In a pre-post analysis we compared the outcome parameters in the inventorial phase (April-July 2006, n = 376) to the implementation phase (April-July 2007, n = 350).

Results: A significant reduction of 1d IV therapy was achieved (6 to 5d in median, p = 0.005) without any increase of relapses, readmissions or death. The crude relative reduction of days of IV antibiotic treatment was 16% (95% CI 4–26%, p = 0.01) and 19% (9%-29%, p = 0.001) after adjustment for age, gender, Charlson index, presence of malignancy and consultation by infectious disease specialist. The main reasons not to switch on day 3 of IV therapy were persisting fever (41% of non-switched patients) and absence of clinical improvement (41%). Two of 698 patients experienced a relapse after early switch; both responded to continued IV antibiotic treatment. A total of 20,000€ of acquisition costs for antibiotics were saved in the year of the intervention in contrast to a 12.5% (+30,000 €) increase of acquisition costs the year before (2005 to 2006). The workload for IV applications was reduced by about 350 hours. There was no similar decrease in antibiotic cost on control wards during the study period.

Conclusions: The implementation of a checklist with clearly defined switch criteria leads to a significant reduction of IV therapy and costs in a university hospital. The proposed bedside checklist can be used safely regarding relapses, readmissions and fatality rate in a mixed population on medical wards.

P1287 Antimicrobial stewardship programme may help reduce antimicrobial resistance in the intensive care unit

L. Pagani, R. Aschbacher, M. Falciani, B. Moser, C. Vedovelli, C. Larcher, P. Mian (Bolzano, IT)

Objectives: Resistance (R) to antimicrobials (AB) is one of the most challenging issues in the management of ICU patients (pts); inappropriate use of AB plays a major role in increasing R.

Methods: from Jan 2002 to Dec 2006, a prospective survey of R patterns among the most important nosocomial pathogens was performed in pts admitted in ICU >48–72 hrs. From 2003, an antimicrobial stewardship program (ASP) has been implemented with the following interventions: I) elimination of 3rd-generation cephalosporin prophylaxis in critical pts at the time of admission to ICU; II) administration of empirical AB therapy of suspected ICU-acquired infections based both on local epidemiology of R and pharmacokinetic/pharmacodynamic (PK/PD) parameters; III) regular (three times a week, or on-call basis) re-evaluation of AB therapy, aiming at stepping-down and shortening duration.

Results: from 2002 (as historical reference) to 2006, the following important decreases in antimicrobial consumption, evaluated in defined daily doses (DDD), have been recorded through the ESGAP ABC Calc 3.1b program: AMK –93.1%; SAM –57.7%; CIP –45%; GEN –88.4%; IPM –60.5%; TEC –95%; VAN –73.3%; CAZ –78.6%. In the same period, MEM and LZD consumption strongly increased (+1620%, and +487%, respectively). Contemporarily, an increase in susceptibility of *S. aureus* to OXA and CIP (from 65.5 to 84.2%, and from 65.7 to 84.3%, respectively), and of *P. aeruginosa* to TZP (from 88.8 to 93.5%), CAZ (from 82.7 to 90.3%), FEP (from 87.5 to 93.5%), AMK (from 93 to 100%) have been observed. However, susceptibility of *P. aeruginosa* to IPM decreased from 75.3 to 45.2%, and production of ESBL increased in *E. coli* and *K. pneumoniae* (from 3.6 to 11.3 and 5.6%, respectively). AB costs did not increase from 2002 to 2006 (109,627.07 and 115,492.63 Euros, respectively) despite a similar number of pts undergoing AB therapy and increased consumption of very expensive AB, such as LZD (49,268 Euros only in 2006).

Conclusion: The ASP yielded to progressive reduction in R patterns of *S. aureus*, and of *P. aeruginosa* to the most important AB. Despite an increased consumption of newer AB, due to an innovative PD-driven approach, the ASP also led to overall expenditure containment.

P1288 Influence of rapid antigen detection test use to antibiotic prescribing for tonsillopharyngitis

A. Berzanskyte, R. Valinteliene, A. Palekauskaite (Vilnius, LT)

Objectives: The aim of the study was to evaluate influence of diagnostic tests to antibiotic prescribing and economical benefit.

Methods: Intervention study was carried out in two randomly selected outpatient (GP) clinics. Intervention consisted of 1) modern knowledge of diagnostics and appropriate antibiotic use for treatment of upper respiratory tract infections, particularly of tonsillopharyngitis, and 2) free rapid antigen detection test (RADT) for Group A hemolytic streptococcus (GABHS), recommendations for its use and interpretation of results. All cases (463) of tonsillopahryngitis from randomly selected patients, who visited GP in 2004, were included in control group. All cases (318) of tonsillopharyngitis from the patients, who visited GP in 2006, till the needed sample size was reached were included in reference group.

Results: After implementation of RADT increase in use of other diagnostic tests was noted. General blood test was performed 1.3 times (p = 0.03), erythrocyte sedimentation rate – 5.9 times (p = 0.00) more often, C-reactive protein test (CRP; not used before intervention at all) was started. The structure of prescribed antibiotics has changed. Penicillin was prescribed 5 times, clarythromycin and cephadroxyl 2 times more often, while broad spectrum penicillins as amoxicillin and amoxicillin with clavulanic acid decreased (respectively 2 and 5 times). Antibiotic prescription rate in general hasn't changed statistically significantly, as discrepancies of prescription rates in both clinics were found – it decreased 1.4 times (p = 0.02) in one clinic, but increased 1.2 times (p = 0.27) in another clinic. Positive RADT result necessitated 23 times more frequent antibiotic prescription than its negative result. However even getting negative RADT result, GPs prescribed antibiotics to 40.4% cases. Proportions of complications and recurrences decreased (respectively 2.1 and 3.7 times). However economical benefit in treatment of tonsillopharyngitis using RADT was gained just in one clinic. Characteristics of used in study RADT were determined: sensitivity

72.3%, specificity 92.3%, positive prognostic value 86.1%, negative prognostic value 83.5%.

Conclusions: After implementation of RADT, other diagnostic tests were used more often, importance of CRP was found in differential diagnosis of tonsillopharyngitis. Prescribed antibiotic structure has changed with the substantial increase of narrow spectrum penicillin.

P1289 A controlled intervention study to improve antibiotic use in a Russian paediatric hospital

D. Berild, T.G. Abrahamsen, S. Andresen, E. Bjørløw, O. Haug, I.M. Kossenko, O.I. Kubar, M. Lelek, S.I. Mintchenko, M.F. Pyasetskaya, S.H. Ringertz, G.S. Sysenko (Oslo, NO; St. Petersburg, RU)

Objective: In a paediatric hospital in Russia a controlled intervention study was performed to improve antibiotic use and to see if improvements persisted. During October, November, and December in 2002 clinical and microbiological data, antibiotic use, costs, and outcome were recorded at two wards for gastrointestinal infections (GII) and two wards for respiratory tract infections (RTI).

Methods: Guidelines of diagnosis and treatment of infections were developed and implemented at one ward for GII and one ward for RTI in 2003. The other two wards served as controls. The same data were recorded during the same 3 months periods in 2003 and 2004.

Results: At the intervention wards the percentage of patients with GII who received antibiotics decreased from 94% in 2002 to 41% in 2003, but increased to 73% in 2004. In RTI these percentages were 90% in 2002, 53% in 2003 and 83% in 2004. The proportions of patients who received antibiotics in 2004 were still lower than in 2002, risk difference (RD) 0.217, $p=0.001$ in GII, and RD 0.073, $p=0.013$ in RTI. From 2002 to 2004 there was a decrease in cephalosporin use ($p=0.021$) and an increase in penicillin use ($p=0.032$) in pneumonia. There was no difference in mortality, duration of fever or duration of hospital stay between the intervention and control wards.

Conclusion: Antibiotic use could be halved without compromising quality of patient care, but one year after the intervention the use of antibiotics approached pre-intervention levels. Strategies to sustain the effect of interventions are needed.

P1290 Impact of a positive Binax NOW *Streptococcus pneumoniae* urinary antigen test on antibiotics policy

M. Matta, A. Buu Hoï, E. Varon, L. Gutmann, J.L. Mainardi (Paris, FR)

Objectives: To evaluate the impact of a positive Binax NOW *Streptococcus pneumoniae* urinary antigen test (UAT) on the use of a targeted anti-pneumococcal therapy for the treatment of community-acquired pneumonia.

Methods: From April 2004 to December 2005, we retrospectively analysed 96 consecutive patients admitted to the emergency room for a presumptive diagnosis of pneumonia with a positive UAT. Patients with associated meningitis were excluded. We reviewed the antimicrobial therapy used before and after the positive result of the UAT, and particularly the proportion of patients under amoxicillin.

Results: Among the 96 patients, 92 were available for the study. Mean age was 64 years (median age 61 y, range 18–99 y) and 49 patients (51%) were male. Eighty nine patients (97%) had a blood or a respiratory tract sample which, in 23 patients (25%), was positive for *S. pneumoniae*. Prior to the UAT result, 22 patients (24%) had no antibiotics, 11 (12%) received amoxicillin, 25 (27%) amoxicillin-clavulanic acid (AMC) or a third-generation cephalosporin (C3G), and 29 (32%) received an association of β-lactam with a macrolide or a fluoroquinolone. Once the physician was informed of a positive UAT, among the 22 patients not treated initially, 7 received amoxicillin secondarily, 7 had AMC or C3G, and 4 had an association. Overall, the number of patients treated with amoxicillin rose to 38 (41%), those receiving AMC or C3G rose to 30 (33%) whereas patients under an association of antibiotics decreased to 12 (13%). Among the 23 patients who had a positive sample for *S. pneumoniae*, 12 had an antimicrobial therapy with a broader spectrum than amoxicillin even once the susceptibility to β-lactams was known.

Conclusions: In case of community-acquired pneumonia at the emergency room, physicians often prefer to prescribe a first line antimicrobial therapy with a broader spectrum than amoxicillin. Although a positive UAT resulted in an increased number of patients treated by amoxicillin alone from 12 to 41 percent, it is noteworthy that in almost 60 percent of the cases antibiotic spectrum was not narrowed.

P1291 The effect of restriction of cephalosporin usage on the incidence of ESBL-producing *Klebsiella pneumoniae* in a tertiary hospital in Cape Town, South Africa

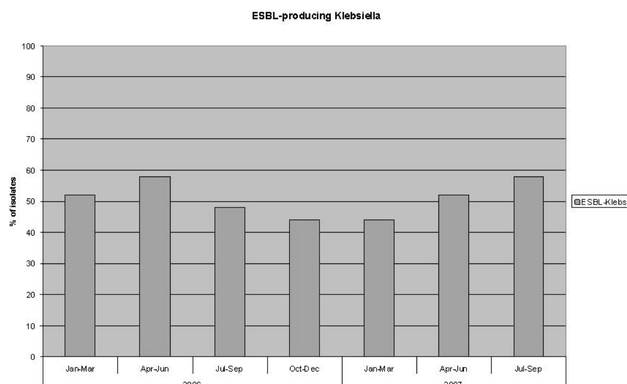
S.P. Oliver (Cape Town, ZA)

Objectives: Several studies have demonstrated a dramatic reduction in the incidence of ESBL-producing organisms when cephalosporin usage has been curtailed. This study seeks to reproduce this effect in a large teaching hospital experiencing an upsurge in ESBL-producing *Klebsiella pneumoniae*. ESBL-producing klebsiellas accounted for around 1% of laboratory isolates in 1994 and had risen to over 60% by 2005.

Methods: Antibiotic usage is controlled in this hospital by the pharmacy requiring release from a microbiologist for certain restricted agents. In May 2006 all cephalosporin usage was restricted except for the use of ceftriaxone for acute bacterial meningitis and cefazolin for surgical prophylaxis. Co-amoxiclav or piperacillin/tazobactam was made available for clinical situations where cephalosporins had previously been used.

Results: Cephalosporin usage dropped by 65%. At the same time co-amoxiclav usage increased by 468% and piperacillin/tazobactam usage increased by 252%.

ESBL-producing klebsiellas appeared to be decreasing during the second half of 2006 but have increased again during 2007. No clustered outbreak of *Klebsiella* isolates was noted at any time.



ESBL-producing *Klebsiella*

Conclusion: The decrease in the incidence of ESBL-producing *Klebsiella* in response to decreased cephalosporin usage appears not to be a sustainable phenomenon in practice.

P1292 Administration of antibiotics via the respiratory tract as monotherapy for pneumonia

M. Falagas, M. Agrafiotis, Z. Athanassa, I. Siempos (Athens, GR)

Objective: Recent studies have shown that antibiotics administered via the respiratory tract may have a role in the prevention of respiratory tract infections. However, the role of aerosolised antimicrobials administered as monotherapy for patients with pneumonia is unclear.

Methods: We endeavoured to accumulate and evaluate the published relevant evidence through searches of PubMed, Scopus, and relevant bibliographies.

Results: Seven relevant studies (1 randomised controlled trial, 4 case series and 2 case reports), including 63 patients, were identified; 37% (23/63) and 63% (40/63) of those patients suffered from community-acquired and nosocomial (including ventilator-associated) pneumonia, respectively. *Acinetobacter baumannii* (41%), Gram-positive cocci (37%), and *Pseudomonas aeruginosa* (16%) were the pathogens more frequently isolated. Colistin (49%), penicillin (37%), and aminoglycosides (17%) were the antimicrobials administered via the respiratory tract. Concurrent systemic antimicrobials (without activity against the isolated pathogens) were given to 33% (21/63) of patients. Clinical cure and bacteriological eradication were observed in 86% (54/63) and 85% (33/39) of patients, respectively. All-cause mortality was 36% (11/31).
Conclusions: The very limited published data preclude any strong conclusions. However, the available data seem to suggest that aerosolised antimicrobial monotherapy for pneumonia should not be a priori excluded in patients without intravenous access, those denying systemic treatment, and in patients with severe toxicity of systemic antimicrobial therapy. Clinicians are encouraged to publish any relevant experience in order for a considerable body of literature to be accumulated.

Bacterial pathogenesis

P1293 Virulence traits of *Escherichia coli* clinical isolates neonatal sepsis. Comparison between strains causing early and late neonatal sepsis

S. Soto, J. Bosch, M.T. Jimenez de Anta, J. Vila (Barcelona, ES)

Objective: Neonatal risk factors for invasive bacterial disease and its diagnosis and therapy remain an important problem for obstetricians and paediatricians. Neonatal meningitis and septicaemia caused by *E. coli* and *Streptococcus agalactiae* are still major health problems in industrialised countries. The objective of the present work was to study the pathogenicity of *E. coli* strains causing neonatal sepsis and to compare those involved in early infection and late infections.
Methods: A total of 54 *E. coli* strains causing septicaemia were collected from neonates between 0 to 28 days-old. Twenty-two and 32 strains have been caused of early or late infection, respectively. Phylogenetic group and the presence of virulence factors were determined by PCR. The type 1 fimbriae expression was tested by agglutination with a *Streptococcus cerevisiae* strain. Proportion and means were compared by using the Chi-square test and t-test.
Results: Twenty-seven (50%), 18 (33%), 6 (11%) and 3 (6%) strains belonged to phylogenetic groups B2, D, A and B1, respectively. The factors more frequently showed by the *E. coli* strains were: fimA (91%), ibe10 (61%), iucC (59%), papEF (56%) and and papC (46%); the virulence factors presented in lesser percentage were: cnf1 and sat1 (6% and 4%, respectively). The ibe10 (ibeA) gene was more prevalent in the strains involved in early infection than in those involved in late infection (86% versus 44%, respectively; p = 0.001).
Conclusion: *E. coli* strains causing early neonatal septicaemia present higher number of virulence factors than those causing late infection. The ibeA gene is more prevalent in the *E. coli* strains causing early neonatal sepsis and it could be involved in the pass of the infection to the amniotic fluid.

P1294 Phylogenetic background and virulence profile of *Escherichia coli* causing neonatal disease

A. Andreu, E. Moreno-Pujol, M. Tenedor, A.M. Planes, S. Molinos, E. Ruiz de Gopegui, J. Bosch and REIPI, the Spanish Network for the Research in Infectious Diseases

Objective: To determine the phylogenetic background and the virulence profile among *E. coli* strains causing neonatal disease, and compared with *E. coli* causing urinary bacteraemia.
Methods: Thirty-five *E. coli* strains, isolated in 4 hospitals within 1996 and 2007, 34 from blood and 1 from blood and CSF, of newborns within the first week of life. We compared them with 50 *E. coli* strains isolated from blood of patients with urinary bacteraemia (Moreno et al. 2005. Diag Microbiol Infect Dis: 53; 93). To these 85 epidemiologically unrelated strains, phylogenetic group and 15 virulence factors were determined by PCR
Results: Among the 35 *E. coli* causing neonatal disease, the highly pathogenic phylogenetic group B2 was the most frequent, 28 isolates (80%), followed by group D with 4 (11%) and group A with 3 (9%). These strains showed a high prevalence of proven virulent traits associated to extraintestinal infections, specially kpsMII (89%), malX (77%), fyuA (91%), and iutA (66%) and a relatively low prevalence of factors associated to P fimbriae: papA 43% and papG alelle II 34%. Factors associated to meningitis were ibeA 21%, and sfa/focDE 46%, but both were present in the strain isolated from CSF. In consequence, these strains showed a high aggregate virulence score with a mean of 6.8, and a range between 2 and 10 virulent factors/strain.
E. coli causing neonatal disease showed a similar distribution among phylogenetic groups than *E. coli* causing urinary bacteraemia (phylogenetic group B2 70%, group D 16%, group A 10%, and group B1 4%), a similar prevalence of virulent traits associated to extra-intestinal infections, kpsMII (76%), malX (70%), iutA (78%), and fyuA (88%), and a similar virulence score 7.2 (range, 1 to 10). However, papA and papG alelle II were statically associated to *E. coli* producing urinary bacteraemia (78% and 66%) in relation to *E. coli* producing neonatal septicaemia (P = 0.001 and P = 0.004; respectively).
Conclusions: *E. coli* producing neonatal disease derived mainly from the pathogenic phylogroup B2 and exhibited a great concentration virulent traits which inferred a virulent potential as high as *E. coli* causing urinary bacteraemia. However, P fimbriae, which enable bacteria to reach the kidney, was significant more prevalent in urinary bacteraemia.
The similarities between *E. coli* causing neonatal septicaemia, urinary bacteraemia and others, strongly suggest that all these *E. coli* should be classified as “Extraintestinal Pathogenic *E. coli* (ExPEC)”

P1295 Detection of pathogenic genes pap, hlyA and cnf1 IN *E. coli* strains isolated from adult patients with urinary tract infection

E. Alepopoulou, M. Panopoulou, T. Konstantinidis, E. Konstantinidou, S. Compelitou, E. Petinaki, S. Kartali (Alexandrupolis, Larissa, GR)

Objective: Urinary tract infection (UTI) is one of the most commonly acquired bacterial infections in ambulatory and hospitalised populations. Most UTIs are caused by *E. coli* strains that exhibit certain virulent factors. Urovirulence factors as pap (pilus associated with pyelonephritis), hlyA (alfa haemolysin) and CNF (cytotoxic necrotising factor) play important role in the pathogenesis of *E. coli* causing of UTI. The present study was comparable in University hospital of Alexandroupolis in northern Greece. The aim was to determine the occurrence of virulence genes expressing pap, hlyA and cnf1 in adult patients with UTI.
Methods: A total 131 strains *E. coli* isolated from urines of 131 adult patients as follow: 103 subjects were women and 29 men. Fifty six strains were isolated from ambulatory and 75 from hospitalised patients. The laboratory criterion for acute *E. coli* UTI was the presence of positive culture on MC agar with of least 105 CFU/ml. The biochemical identification of the strains was performed by automated system VITEK2 (BioMerieux). Specific primers were used to amplify sequences of the pap, hlyA and cnf1 genes. Amplification products 336bp, 1177bp and 498 bp respectively were electophoresed in 2% agarose gel and visualised by ethidium bromide staining.
Results: Overall, of the 131 isolates strains *E. coli* 67(51%) carried pathogenic genes. From 67 strains 28(42%) were isolated from ambulance patients and 54 (80%) from women. The genes pap, hlyA and cnf occurred in several combinations. The combinations of pathogenic genes were as follow: 22 (33%) strains yielded pap gene, 2 (3%) hlyA, 9(13%) cnf1, 9 (13%) pap+cnf1, 8(12%) pap+hlyA, 3 (4%) cnf1+hlyA and 14 (20%) pap+cnf1+hlyA. From 22 strains pap+ and

14 strains (pap+cnf1+hlyA)+ 86% and 90% respectively were isolated from women.
Conclusion: Sixty seven (51%) *E. coli* isolates were found to carry at least one pathogenic gene. The most prevalent pathogenic gene was pap and combination pap+cnf1+hlyA. The frequency of pathogenic genes was higher in women, specifically in regard of strains with genes pap and pap+cnf1+hlyA.
The presence of pathogenic genes in *E. coli* contributes to colonisation, invasion, promote biofilm formation and persistence of strains in the urinary tract. Therefore knowledge of pathogenic genes of the microorganisms causing the UTI it would anticipate the evolution of infection in the host

P1296 Distribution of virulence factors in *E. coli* strains isolated from women with urinary tract infection by PCR

E. Alepopoulou, M. Panopoulou, E. Konstantinidou, T. Konstantinidis, D. Kalpini, S. Kartali (Alexandrupolis, GR)

Objective: *E. coli* is the most common cause of urinary tract infections (UTI). A variety of urovirulence factors are overrepresent in uropathogenic *E. coli*, including fimpriae and adhesins, cytotoxins such as a-haemolysin and cytotoxic necrotising factor 1, aerobacin-mediated iron uptake system and others. The dominance of strains expressing multiple urovirulence factors may further increase the risk for development of UTI specifically in women. In the present study, that was comparables in University hospital of Alexandroupolis in northern Greece, we analysed the distribution of genes pap, hlyA, cnf1, aer, sfa and afa in *E. coli* strains isolated from women with UTI.
Methods: A total of 103 strains *E. coli* were isolated from 103 women 18 to 83 years old with UTI. The laboratory criterion for acute *E. coli* UTI was the presence of positive culture on MC agar response with at least 105 CFU/ml. Multiplex PCR was performed to detect urovirulence genes pap, hlyA, cnf1, aer, sfa, afa in *E. coli* strains. Amplification products 336bp, 1177 bp, 498 bp, 602 bp, 410 bp and 750 bp respectively were electophoresed in 2% agarose gel and visualised by ethidium bromide staining.
Result: Seventy seven (75%) of the 103 strains *E. coli* were found to carry at least one urovirulence gene. Frequencies of genes pap, hlyA, CNF, aer sfa, afa in total 103 isolates were estimated as 45%, 20%, 25%, 47%, 27% and 6% respectively. The data indicated that 2%, 8%, 14%, 17%, 27% and 6% isolated carried six, five, four, three, two and one virulence factor respectively. However no virulence factors were found in 26 (25%) isolates.
Conclusion: The *E. coli* strains expressing multiple virulence factors comprise frequent cause developing UTI. The results showed that 75% of *E. coli* isolates carried at least one virulence factor. The occurrence of pap and aer was higher compared with the rest of others genes. In contrast, afa gene was carried in only 6 strains. Also in the present study was demonstrated that the multiplex PCR is an efficient tool for rapid detection and identification of UTI virulence factors in *E. coli* isolates.

P1297 Identification and genotyping of uropathogenic *Escherichia coli* strains isolated from patients with urinary tract infection based on papC and papG genes using PCR

B. Zamanzad (Shahrekord, IR)

Introduction: *Escherichia coli* (*E. coli*) is the most common aetiologic agent of Urinary tract infections (UTIs). The most important virulence factor in Uropathogenic *E. coli* (UPEC) strains is P fimbriae. P fimbriae is coded by pap(pyelonephritis associated pili) operon. PapG is the most common adhesin in this fimbriae and papC is an important gene in this operon. Fimbriated uropathogenic strains of *E. coli* have an important role in causing UTI especially upper tract infections. In this study prevalence of pap operon (papC and papG genes) in *E. coli* strains isolated from nosocomial UTIs were evaluated.
Methods: A total of 182 *E. coli* isolates cultured from patients with different clinical forms of UTI referred to Shahre-kord teaching hospital were included. DNA of bacterial isolates was extracted by boiling method. PCR method was performed for presence of papC (pap operon) and papG genes. Also, genotyping of papG (pap operon) positive isolates were performed using multiplex PCR method.
Results: The prevalence of pap operon in isolates was 36.2%. Genotyping of P fimbriated isolates for papG gene by multiplex PCR method showed the prevalence of class 2 and class3 of papG gene, 23.1% and 6.6% respectively. None of the isolates had class 1 genotype. Furthermore, papG class 2 was predominant in patients with pyelonephritis and papG class 3 was predominant in ones with cystitis. In this study, no relationship between the presence of P fimbriae and sex of the patients was detected.
Conclusion: PapC (and papG)) genes have important roles in pathogenesis of fimbriated uropathogenic strains of *E. coli*. We recommend detection and genotyping of these genes in complicated UTIs in hospitalised patients enabling specific diagnosis and treatment of nosocomial infections with urinary tract origin.

P1298 Clonality and presence of fimbrial adhesin genes of *Escherichia coli* isolated in recurrent cystitis from a 48-year-old female

V. Rodrigues, S. Simões, M. Morgado, D. Morgado, T. Hanscheid, J. Melo-Cristino, A. Duarte (Setubal, Lisbon, PT)

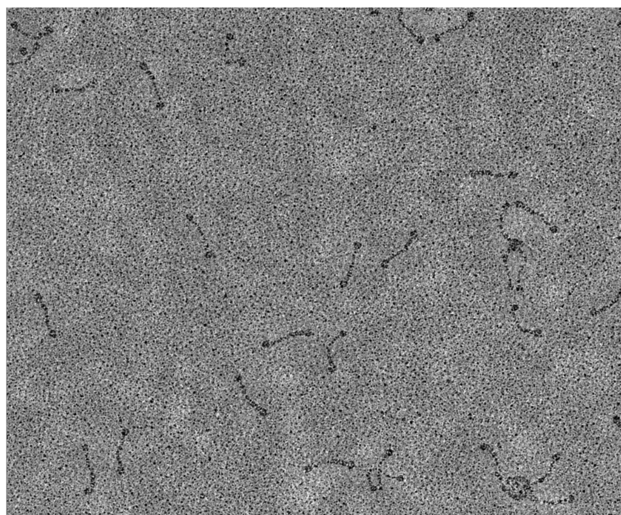
Objectives: Urinary tract infections (UTI) are a common healthcare problem. Recurrent UTI in healthy, nonpregnant women is defined as three or more episodes of UTI during a 12-month period. It affects an estimated 20% of women at some time during their lifetimes. The uropathogenic *E. coli* (UPEC) possess adherence factors called pili or fimbriae (type 1 and P), which allow them to successfully initiate UTI infections. This adhesins are involved in the colonisation of mucosal cells, proliferation and cell damage, thus increasing the time of survival in the host. The aim of this study was to determine the occurrence of virulence genes and verify the clonal relation of *E. coli* isolates from recurrent cystitis.
Methods: A total of five *E. coli* isolates were recovered from a 48 year old female with recurrent urinary tract infection. Three strains were isolated from urine during six months and two strains were isolated from perineum and rectal swabs, respectively. Identification and antimicrobial susceptibility testing was determinate by VITEK 2 system. The presence of fimbrial adhesins was performed by PCR, using two pairs of primers: PAP1/PAP2 and fimH_F/fimH_R that amplify type P and type 1 fimbrial adhesins, respectively. Clonal relationship was assessed by M13 fingerprinting.
Results: The strains showed the same resistance profile and were resistant to trimethoprim/sulfamethoxazole, ciprofloxacin, norfloxacin, and showed susceptibility to cephalosporins (2nd and 3th generation), nitrofurantoin and fosfomycin. All strains exhibited the type 1 fimbrial adhesin and the same M13 fingerprint profile, including the strains identified from perineum and rectal swab. These results suggest that recurrent infections are due to the patient's inability to eliminate the microorganism (relapse), and not by reinfection, since all strains isolated in the period of 6 months belong to the same clone.
Conclusions: One of the main factors for the occurrence of urinary tract infections is the presence of adhesins, allowing the adherence of bacteria to uroepithelium hindering its removal, even after therapy.

P1299 Collagen-like proteins from the enterohaemorrhagic *E. coli* strain O157:H7

N. Ghosh, I. Roberts, J. Bella (Manchester, UK)

Many phage and bacterial genomes contain collagen-like sequences. The *Escherichia coli* strain O157:H7, a serious enterohaemorrhagic pathogen, has eight putative collagen-like genes that are missing in harmless *E. coli* strains. To help establish if collagen-like proteins contribute to O157:H7 virulence we have cloned one of these genes, EclA, into a laboratory strain and analysed it biophysically. Analytical ultracentrifugtion and

dynamic light-scattering showed that EclA is trimeric in solution, with a molecular weight of 132 kDa. EclA forms characteristic dumbbell-shaped structures visible in electron microscopy images. The "stalk" region adopts a collagen triple-helical conformation with a maximum ellipticity at 220 nm demonstrated by CD spectroscopy, while the CD of full-length EclA is dominated by alpha-helical structure localised to its N-terminal region. The thermal denaturation of the stalk showed a single transition at 42ºC, much higher than that of mammalian collagens, that was consistent with the loss of triple helical structure. On the other hand, full-length EclA showed two transitions: the first transition at approximately 42ºC corresponds to loss of triple-helical structure; the second one at 52ºC corresponds to loss of alpha-helical structure. The first transition is much higher than the equivalent seen for mammalian collagens. The results show that EclA behaves like an unexpectedly stable collagen protein. While the function of these proteins needs to be elucidated, mRNA transcripts of collagen-like genes were detected by RT-PCR both in stationary and exponentially growing cells, suggesting protein expression and functional significance.



P1300 **Intracellular crystallisation caused by *Proteus mirabilis* plays a significant role in recurrent urolithiasis**

A. Torzewska, A. Budzynska, M. Bialczak-Kokot, A. Rozalski (Lodz, PL)

Objectives: *Proteus mirabilis* are the most common bacilli associated with the formation of bacteria-induced bladder and kidney stones. In 50% of cases, this is recurrent illness, which can lead to the loss of kidneys if not properly treated. Bacterial urease is the essential virulence factor in stones formation. Ammonia, produced by the enzymatic hydrolysis of urea, elevates urine pH causing a supersaturation and crystallisation of struvite and apatite. Crystals may grow intra as well as peribacterially. The aim of this work was to show that *P. mirabilis* bacilli can grow and form crystals inside urothelial cells. In this enviroment bacteria may be protected against antibiotic killing and thus cause persistent or recurrent infections.

Methods: *P. mirabilis* strains were recovered from encrusted biofilm on Foley catheter of long-term catheterised patients. The in vitro model was used to analyse intracellular growth and crystallisation. In this model human renal (HRPTEC), ureter (Hu 608) and bladder (HCV 29) epithelial cells were infected and incubated (3–72 h) in the presence of synthetic urine and amikacin to prevent extracellular bacterial growth. Number of intracellular bacteria was determined after host cells lysis by plating lysates on TSB plates. Crystallisation was determined using radioactive isotope of calcium. Crystals and bacteria were also observed by crystal violet and van Kossa method staining.

Results: It was found that *P. mirabilis* isolated from urinary catheter demonstrated a significant ability to adhere and penetrate normal urothelium, especially Hu 608 cell lines. These strains could multiply intracellularly within epithelial cells and were able to induce crystallisation. From 24 to 72 hours after infection a degree of crystallisation increased and it depended on the number of bacteria within host cells. This finding was confirmed by microscopy. The dark deposites of calcium salts within infected epithelial cells were observed.

Conclusion: Our results showed *P. mirabilis* ability to persist and form crystals inside the host cells, despite antibiotics presence. In this situation bacteria induce infection, usually chronic, which commonly results in the formation of bladder and kidney stones.

P1301 **Comparison of the invasiveness properties of Iranian *Shigella flexneri* wild type vs. mutants by cell culture and electron microscopy**

M. Hakemi vala, J. Nowroozi, P. Nabavi tabatabaii, P. Kavakeb (Tehran, IR)

Objectives: Among pathogenic microorganisms, invasive bacteria such as shigella has the ability to penetrate mammalian epithelial cells both in vivo and in vitro. Morona etal, produced a *S. flexneri* mutant and showed invasiveness of mutants decreased compared to wild types. So, the aim of this study was comparing the invasiveness properties of the *S. flexneri* wild types (icsA+ strains) v.s *S. flexneri* mutants (icsA defected) by cell culture and electron microscopy.

Methods: *Shigella flexneri* strains were isolated by standard bacterial methods from faecal specimens of children attending to the 3 children's hospitals of Tehran between January 2003 to December 2003. DNA isolation, was done by sodium perchlorate 4M method. Existence of icsA gene was determined by PCR. Mutation forming was done by allelic exchange and using pCACTUS-icsA:: amp r. HeLa cell culture were prepared using MEM medium and Fetal calf serum and infected with both *S. flexneri* wild types and mutants strains

Continuously, electron microscopy investigation was done after fixation, using resin spur and staining gold sections with saturated Uranyl acetate and Lead citrate.

Results: From 100 *S. flexneri* strains recovered from stool specimens, 46% were icsA + by PCR. All transformed bacteria were selected by temperature sensitivity and sucrase levan production and resistance to ampicillin. Further PCR on mutants showed no PCR product detection. Invasive shigella strains penetrated in to HeLa cells compare to mutants which may adhered but not entered. Further more, pseudopod structures used to facilitate bacterial cell-to-cell spread were readily identified by electron microscopy in wild types.

Conclusion: In this study, all clinical isolated *S. flexneri* wildtypes which were IcsA+, showed similar internalisation, cell existence and cell disruption. In addition, pseudopod filaments were confirmed with electron microscopy. In contrast, most of mutants icsA– could not enter to HeLa cells. Moreover, a few number of these bacteria could adhere and enter to the HeLa cells, but cell disruption was not detected. These bacteria might produce necrosis later, but not detected after 3 h incubation.

P1302 **GATC sites might regulate virulence of *Salmonella typhimurium***

A. Chatti, A. Landoulsi (Zarzouna, TN)

Background and Objectives: Pathogenesis of Salmonellosis depends upon a large number of factors controlled by an array of genes that synergise into the actual virulence of *Salmonella*. A study was undertaken to observe the effect of dam and/or seqA on the virulence and stress response of *Salmonella typhimurium*.

Methods: All experiments described in this paper were carried out with *Salmonella enterica* serovar Typhimurium strain SL1344, LT2, and their isogenic mutants dam– and seqA–, respectively. For the virulence test, we are used LD50, competitive index (CI) and bacterial enumeration from target organs such as liver and spleen. For the study of the effect of dam or seqA mutation on the stress response, we have chosen to

study response of these mutants toward bile, acidity, oxygen peroxide and antimicrobial peptides were tested.
Results: Our results show that dam or mutation attenuates *Salmonella* virulence either after intraperitoneal or oral infection. LD50, CI and enumeration of these mutants in liver and spleen prove a significantly decrease of virulence. On the other hand, in our work we are demonstrating that dam and seqA gene might control *Salmonella typhimurium* stress response (acid, bile, H2O2 and antimicrobial peptide).
Conclusion: Findings indicated that the dam and seqA genes may regulate virulence and stress response. We suggest that GATC distribution among DNA can regulate virulence and stress response of *Salmonella typhimurium*.

P1303 stj fimbrial operon has a role on *S. typhimurium* pathogenicity

M.D. Avsaroglu, N. Akkoc, M. Akcelik (Ankara, TR)

Objectives: To exhibit the role of stj fimbrial operon on the patogenicity of S. Typhimurium by animal experiments using mice model system.
Methods: The left and the right-end fragments of stjA gene were amplified with following primers; left-end F primer having BglII cutting site: GCAGATCTGCGGAAGTGATTTCACCGG/B primer having SalI cutting site CGGTCGACCCAAATGACATGTAAT-GCGCGGGTCGGG; right-end F primer having SalI cutting site: CGGTCGACCTCCAGCATTCACATGGAATATTCAACACC/B primer having XbaI cutting site GCTCTAGATCCAGTTTCACACCATTGTCG-GTC. Amplified fragments were than cloned to pGB704 vector plasmid. A kanamisin gene cassette was inserted between the two fragments on the vector plasmid. The recombinant plasmid was transformed to the S. Typhimurium IR 715 strain by conjugation. By the aid of left and the right-end fragments of stjA gene on the vector plasmid homolog recombination was occurred with the stjA gene on the chromosome of the host and the gene was knocked-out with kanamisin gene cassette. Animal experiments were performed with the mutant and wild type strain of S. Typhimurium.
Results: The experiments based on the competition between the wild type strain and degenerate mutant strain of stj operon. To construct the knocked-out mutant strain, one of the five genes in the operon, stjA, was degenerated with the kanamisin gene cassette on the plasmid pGP704. The mutants were named S. Typhimurium MA44 and used in animal experiment as knocked-out mutant strain of stjA gene. In the animal experiments, mice model system was used. AJB715 (S. Typhimurium lack of acid phosphotase activity) was used as the stjA wild type strain. 6–8 week female mice were inoculated orally with MA44 and AJB715. Viable cells in faeces and organ samples were counted and analysed statistically. It was observed that there was a significant ($p < 0.05$) reduction in the number of MA44 mutant strain in comparison to AJB715 wild type strain.
Conclusions: The results exhibited that stj operon plays an important role in the pathogenicity of S. Typhimurium by effecting the reproduction and stability functions of host organism in the target tissue systems.
Acknowledgements: This work was supported by the Scientific and Technological Research Council of Turkey (TUBITAK) grant 107T459.

P1304 Prevalence of virulence genes among nosocomial and cystic fibrosis isolates of *Pseudomonas aeruginosa* from Bulgaria

T. Strateva, B. Markova, I. Mitov, V. Ouzounova-Raykova, G. Petrova (Sofia, BG)

Objectives: To study the prevalence of different virulence factors (adhesins, invasins and type III effector proteins) in clinical isolates of *Pseudomonas aeruginosa* and to perform a comparative analysis of their incidence according to the patients' population, localisation of infection and antimicrobial resistance of the strains.
Methods: A total of 202 clinical *P. aeruginosa* isolates obtained from in-patients and cystic fibrosis (CF) patients was collected during 2001–2006 from five university hospitals in Sofia, Bulgaria. Polymerase chain reaction amplification and sequencing were carried out to determine the distribution of the following virulence genes: algD (encoding alginate), pilB (type IV pili), nan1 (neuraminidase), lasB (elastase B), plcH (haemolytic phospholipase C), exoS (exoenzyme S) and exoU (exoenzyme U).
Results: The frequencies of virulence genes in all studied strains were: algD – 91.1%, pilB – 23.8%, nan1 – 21.3%, plcH – 91.6%, lasB – 100%, exoS – 62.4%, exoU – 30.2%. The prevalence of nan1 was higher in CF respiratory isolates (38.1%) than in non-CF isolates (16.9%) – $P < 0.01$. The distribution of pilB (9.5%) and plcH (71.4%) among CF isolates was lower than in non-CF nosocomial strains (respectively, 26.9% ($P < 0.01$) and 96.9% ($P < 0.001$)). The dissemination of virulence genes varied according to the localisation of nosocomial infections in non-CF patients. The relative proportion of multidrug-resistant (MDR) nosocomial strains of *P. aeruginosa* expressing a great number of virulence factors ($\geqslant 5$) (38.1%) was higher than the proportion of non-MDR isolates with a great number of virulence factors (17.6%) – $P < 0.01$.
Conclusions: The neuraminidase plays a key role in CF pulmonary disease evolution. Nonpilus adhesins such as the slime layer composed of alginate are the major virulence factors for attachment of *P. aeruginosa* to the respiratory epithelial cells in CF patients. Combined horizontal gene transfer and recombination of pathogenicity islands and mobile genetic elements containing antimicrobial resistance genes are the probable causes for selection of MDR *P. aeruginosa* strains with a large number of virulence factors.

P1305 Quorum sensing-deficient respiratory isolates of *Pseudomonas aeruginosa*

O. Karatuna, A. Yagci (Istanbul, TR)

Objective: *Pseudomonas aeruginosa* (PA) is an opportunistic pathogen which produces several virulence factors including elastase, alkaline protease, pyocyanin and rhamnolipid. The genes for these products are often controlled by quorum sensing (QS) systems. In PA, two QS system were identified, LasR/I and RhlR /I. We tried to analyse QS regulated virulence factors of respiratory PA isolates and determine QS deficient ones.
Methods: PA strains (n: 100) isolated from lower respiratory tract infections were used. Production of elastase, alkali protease, pyocyanin and biofilm were quantified spectrophotometrically. PA01 strain was used as a standard reference strain. Forward and reverse primers for LasI, LasR, RhlI, RhlR were used for polymerase chain reaction(PCR) amplification of QS genes. Evaluation of biofilm-forming ability and genetic typing was done by ERIC-PCR. Antimicrobial resistance was determined by agar diffusion.
Results: Production of biofilm was detected in 49 strains, whereas 45 strains elastase, 53 strains alkaline protease and 31 strains were pyocyanin positive. In 16 of the patients any of these factors were found to be positive. Virulence factor negative strains were not cumulated in a antibiotic susceptibility pattern or a genotypic subgroup. Four of the QS related genes were negative in only 3 of the 16 strains.
Conclusion: Depending on the infected tissue some virulence factors play more important roles than the others in the pathogenesis of PA infections. During the infection some virulence factors may compensate for the loss of any single virulence factor. The impact of spontaneous loss of several virulence factors on the colonisation and infection process is not well known. Although in 16 of our PA isolates none of the 4 virulence factors were detected phenotypically, genes responsible for the production for these factors were negative in only 3 of them suggesting low reliability of phenotypic tests. We can also conclude that PA strains that lack functional QS can still produce infection.

P1306 ***Stenotrophomonas maltophilia* isolated from patients affected by cystic fibrosis: genotyping analysis and molecular characterisation of virulence determinants**

E. Fiscarelli, A. Iacobino, M. Nicoletti, B. Colonna, G. Prosseda, M. Casalino (Rome, Chieti, IT)

Objectives: In recent years *Stenotrophomonas maltophilia* has gained considerable attention being one of the most prominent emerging pathogens in the airways of CF patients. The role of *S. maltophilia* in the pathophysiology of the CF lung disease has not been clearly elucidated, but a progressive deterioration in pulmonary function has been observed, particularly in patients chronically colonised for longer periods. Despite its increasing role as a human pathogen, little is known about the bacterium, particularly with regard to putative virulence factors. Due to the remarkable diversity among isolates it is extremely important to acquire a better definition of bacterial clones or lineages able to cause disease in CF patients.
Methods: *S. maltophilia* clinical strains, isolated from CF patients at the "Bambin Gesù" Hospital in Rome (OBG collection), were analysed for genomic diversity by Pulse Field Gel electrophoresis (PFGE) and restriction length polymorphism of the gyrase B gene (gyrB RFLP). By Subtractive Suppression Hybridisation (SSH) genome analysis, we started to identify specific DNA regions selectively present in *S. maltophilia* OBGTC9, a persistent CF clinical isolate.
Results: While the gyrB RFLP analysis allows to group our *S. maltophilia* strains into few clusters, PFGE reveals a high genomic diversity despite their origin from a single hospital. As far as the identification of potential virulence factors is concerned, we have obtained a SSH library and we have identified some specific DNA fragments present in *S. maltophilia* OBGTC9. These genomic regions are not widespread among the *S. maltophilia* strains of the OBG collection, but rather associated only with two strains (OBGTC9, OBGTC10) able to establish persistent infections in CF patients.
Conclusions: We have analysed a group of *S. maltophilia* clinical strains, stemming from persistent or sporadic infections from respiratory secretions of CF patients, for genomic diversity and for the presence of virulence traits which may contribute to the pathogenicity process. PFGE reveals a high genomic diversity of *S. maltophilia* isolates despite their origin from a single hospital. Moreover, by SSH analysis we have identified specific DNA regions present only in two *S. maltophilia* strains (both persistent CF clinical isolates), which may be considered putative virulence factors in chronic infection.
This work is supported by the Italian Cystic Fibrosis Foundation (Grant 7/2007)

P1307 **Antibody response of cystic fibrosis patients with *S. maltophilia* infection/colonisation to the *S. maltophilia* fimbria SMF-1**

A.C. Azzuz-Chernishev, L..V. da Silva Filho, D. de Oliveira-Garcia (São Paulo, BR)

Objectives: *S. maltophilia* is an opportunistic pathogen with controversial role in lung disease of cystic fibrosis (CF) patients. This bacterium expresses fimbria (SMF-1) that may be involved in bacterial adherence to epithelial cells (de Oliveira-Garcia et al, Cel. Microbiol., 5: 625–636, 2003). It was evaluated the antibody response of cystic fibrosis (CF) patients naturally infected/colonised with *S. maltophilia* against SMF-1.
Methods: Twenty-three *S. maltophilia* isolates were obtained from respiratory tract of 13 CF patients attending to Pulmonology Unit of Medical School of University of São Paulo, São Paulo, Brazil. *S. maltophilia* isolates were identified by classical phenotypic tests and by PCR and DNA sequencing in some cases. Whole cells were submitted to imunnoblottings using rabbit antiserum raised against SMF-1 to assess SMF-1 production. Also human sera obtained from CF patients colonised/infected with *S. maltophilia* were used against SMF-1 purified to verify the production of antibodies. It was used goat anti-human IgG and anti-rabbit IgG conjugated to horseradish peroxidase as secondary antibodies. Other Gram-negative bacteria and human sera obtained from patients without *S. maltophilia* infection/colonisation were used as negative control. SMF-1 purified and rabbit antiserum raised against SMF-1 were used as positive control.
Results: All *S. maltophilia* isolates produced SMF-1. All human sera tested reacted with SMF-1. Sera from 04 patients presented high title (1:500), and 02 of these patients had clinical or pulmonary function decline and sera from one patient presented title 1:2 500.
Conclusion: The presence of antibodies against fimbria is a marker for infection and production of these antigens in vivo. SMF-1 was produced in vivo during natural *S. maltophilia* infections/colonisations and elicited an immune response against it. This is the first description about the production of human antibodies against SMF-1.
Financial support: FAPESP (02/13111–0)

P1308 **First description of *Staphylococcus lugdunensis* internalisation into epithelial cells**

F. Szabados, B. Heck, S. Rodepeter, M. Kaase, B. Kleine, T. Sakinc, I. Schmitz, S. Gatermann (Bochum, DE)

Objectives: *Staphylococcus lugdunensis* belongs to coagulase-negative Staphylococci(CoNS) and can occasionally cause serious invasive infections such as osteomyelitis and infective endocarditis. *S. lugdunensis* accounts for 18% of infective endocarditis and 44% of native valve endocarditis caused by CoNS. *S. lugdunensis* expresses potential virulence factors, including synergistic toxins, haemolysins, extracellular enzymes, several adhesion factors, which mediate binding to collagen type I and IV, human IgG, fibronectin and fibrinogen. Furthermore, a fibrinogen-binding protein (Fbl), with a high homology to clumping factor A of *S. aureus* has been described.
We therefore sought to investigate internalisation of several *S. lugdunensis* blood culture isolates into different epithelial cell lines.
Methods: Internalisation into the human bladder carcinoma cell line 5637 and Hep2 cells were measured using a FACS-based method as described previously. The bacteria were stained with FITC and were incubated for one hour with the cells, gentamicin and lysostaphin was added for half an hour. The cells were washed and treated with trypsin to remove adhering bacteria and to detach the eukaryotic cells. For further discrimination, a gating strategy was used, because bacteria were smaller in size and FITC stained.
Results: The internalisation of several *S. lugdunensis* blood culture isolates was significantly increased in contrast to non-invasive *S. carnosus* TM 300. Internalisation ratio was slightly less compared to *S. aureus* Cowan I strain.
Conclusion: Our experiments demonstrate for the first time internalisation of *S. lugdunensis* clinical isolates into epithelial cells in a FACS invasion assay. These results were in line with the clinical suspected invasive ability of this pathogen. Internalisation into eukariotic cells could explain an important step of *S. lugdunensis* pathogenicity in serious infections e.g. endocarditis in analogy to mechanisms described for *S. aureus*.

P1309 **The signal peptide of Panton-Valentine leukocidine LukS component induces increased adhesion to extracellular matrix components in *Staphylococcus aureus***

A. Tristan, Y. Benito, E. Dusserre, M.G. Bowden, J. Etienne, G. Lina, F. Vandenesch (Lyon, FR; Houston, US)

Staphylococcus aureus necrotising pneumonia is a highly severe disease due to *S. aureus* strains carrying the Panton Valentine leucocidin (PVL) genes (lukS-PV & lukF-PV) encoded on various bacteriophages (such as phiSLT). PVL is a pore forming toxin inducing polymorphonuclear cell death by necrosis (at high concentration, 200 nM) or by mitochondrial pathway induced-apoptosis (low concentration 5 nM). However, clinical PVL+ strains from necrotising pneumonia display additional properties such as increased adhesion to matrix molecules (type I and IV collagens and laminin) that could play a role in bacterial adhesion to damaged airway epithelium in the course of necrotising pneumonia.

To investigate the basis of this increased adhesion to matrix proteins we transduced phiSLT in various *S. aureus* clinical and laboratory strains, and tested these strains for adhesion to various matrix molecules and to matrigel® (a solubulised basement membrane preparation).
Transduction of phiSLT in different backgrounds produced an adhesion phenotype to collagen I and IV, laminin, elastin and matrigel®, similar to that observed with clinical PVL+ strains. In addition, independent expression of each of the PVL component in the laboratory strain RN6390 induced the same adhesion phenotype with an effect more marked for lukS-PV than for lukF-PV. Cloning and expression of various LukS-PV sub-fragment revealed that the 28 aa signal peptide of LukS-PV induced this adhesion phenotype. A synthetic LukS-PV signal peptide but not other unrelated signal peptide, produced the same adhesion phenotype in vitro. This study shows for the first time in bacteria the potential post-secretory function of a bacterial signal peptide. One hypothesis is currently investigated: the cleaved signal peptide could be released outside the cytoplasmic membrane and, after non-covalent linking to the peptidoglycan or teichoic acids, could function as an adhesin for the matrix proteins.

P1310 Extracellular adherence protein of *Staphylococcus aureus* in wound infections: surprising differences in transcription and expression in vivo and in vitro

I. Joost, D. Blass, M. Burian, C. Goerke, M. Bischoff, M. Herrmann (Homburg, Tubingen, DE)

Objectives: The extracellular adhesion protein (Eap) of *S. aureus* belongs to a group of secreted proteins that are non-covalently bound to the cell surface and exerts versatile effects that fulfil prerequisites for chronic, persistent infections: Adhesion to extracellular matrix molecules, endothelial (EC) and other cells, reduced angiogenesis and EC proliferation, immunmodulation and delayed wound healing in mice. Although eap is prevalent in 100% of clinical isolates, only little is known whether and how eap is transcribed and expressed by clinical isolates under in vivo and in vitro conditions. Objectives of the study were the examination of the eap transcription in vivo from human wounds and in vitro under defined conditions as well as the corresponding protein expression.
Methods: RNA-Isolation: RNA was isolated using a modified Trizol protocol. Wound swabs were snap frozen in liquid nitrogen immediately.
Quantification of eap transcription: Quantification was done by RT-PCR using specific RNA standards for eap and gyrB.
Protein detection: Standard protocols for isolation of proteins from supernatants and cell-wall attached proteins were applied.
Results: Our analyses show that eap is transcribed by all clinical isolates in a strain- and growth phase-dependent manner. Under in vivo conditions, transcription of eap was found to differ with the degree of infection, with severe infections possessing the highest eap expression, which was up to 500-fold higher than under in vitro conditions. Strains causing wound infections seem to have the capability to transcribe eap on a higher level than strain Newman, so far known to be the highest Eap producer. While most of the synthesised Eap in Newman is found non-covalently bound to the cell surface, we were not able to detect significant amounts of Eap either in the cell surface fractions or the supernatants of the wound isolate cultures.
Conclusions: Our results prove that eap is transcribed by all clinical isolates tested. Interestingly, eap transcription seemed to correlate with the degree of infection, with eap being transcribed at a higher level under severe conditions than in superficial infections. Surprisingly, eap transcription of clinical isolates did not appear to correspond with protein production, indicating either differences in transcription- and translation efficiencies, or a rapid turn-over of Eap in the culture supernatants of these strains.

P1311 *Staphylococcus aureus* encoding both TSST-1 and PVL in the UK

A.M. Kearns, I. McCormick Smith, M. Ganner, C. East, M. Warner, R.L. Hill, M.J. Ellington (London, UK)

Objectives: TSST-1 and PVL are superantigenic, synergohymenotropic toxins that have been associated with toxic shock syndrome and necrotising pneumonia, respectively. These toxins are rarely reported in the same strain of *S. aureus*. We sought to determine the genetic diversity and clinical impact of such isolates across England and Wales during 2005–7.
Methods: *S. aureus* referred to the national Staphylococcus Reference Laboratory from 2005 to September 2007, and that tested positive by PCR for the presence of toxin genes including the lukSF-PV and tst were retained for study. Isolates were characterised by spa typing, SmaI PFGE and MLST, as appropriate. In addition: agr allotype, SCCmec type and ccr type were determined together with MICs of a wide range of antibiotics. Patient demographic and clinical data were retained for analysis.
Results: Five MRSA and 16 MSSA encoding TSST-1 and PVL were identified. These were geographically and temporally unrelated. The five MRSA were from four paediatric patients (3 male) and one 65 year old female. Two isolates were from abscesses, one each from a nasal swab and eye infection, and one of unknown source. The MRSA were SCCmecIV, related to known ST5, 22 and 30 isolates by PFGE and spa typing, and were resistant to up to three antibiotic classes, in addition to β-lactams. Six of 16 MSSA were from males and nine from females. Available data indicated the age range was <1 to 58y (mode = 0 y, median = 31 y). Three isolates were associated with pneumonia, 1 with bacteraemia, 1 with wound infection, 2 with abscesses, 1 was from pus and 5 were from screening swabs. The MSSA isolates were genetically diverse (including ST5, 22 and 30), 1 isolate was resistant to ciprofloxacin, 9 resistant to tetracycline and 2 were resistant to trimethoprim.
Conclusion: Diverse lineages of *S. aureus* encoding both TSST-1 and PVL have been identified sporadically in geographically distinct areas of the UK. Resistance to multiple antibiotics was noted in MRSA, but MSSA isolates remain largely susceptible. Like other PVL positive *S. aureus*, these strains have a predilection for the young with attendant impact on clinical management and empiric therapeutic strategies.

P1312 Acid tolerance of *Streptococcus anginosus*

M. Sasaki, S. Tajika, Y. Kodama, Y. Shimoyama, S. Kimura (Morioka, JP)

Objectives: Streptococci belonging to *Streptococcus anginosus* comprise a large proportion of the resident oral microflora. In recent years, however, it has emerged that *S. anginosus* infection could be closely related with oral, esophagus and gastric cancers. Since the surfaces of these organs are generally acidic conditions, the aciduricity, the ability to survive and grow under conditions of low pH, of *S. anginosus* may be associated with the upper gastrointestinal cancers. To elucidate the aciduricity and the acid tolerance mechanisms of the microbes, in this study, we examined the viabilities and growth of *S. anginosus* in acidic conditions, and the putative acid tolerance mechanisms, the ATPase and arginine deiminase (ADI) activities, were compared to those of other oral streptococci.
Methods: *S. anginosus* ATCC 10713 and the clinical isolates, and other oral streptococci, *S. mutans* ATCC 25175, CS. sanguinis ATCC 10556, CS. gordonii ATCC 10558, CS. mitis ATCC 9811, CS. oralis ATCC 10557 and *S. salivarius* ATCC 7073, were used. The aciduricity of the bacteria was assessed by the viabilities of preacidified bacteria and the growth in acidic conditions by means of the culture methods using Todd Hewitt agar. The ATPase and ADI activities were measured by the colorimetric methods on the permeabilised bacterial cells.
Results: Among the seven oral streptococcal species tested, *S. anginosus* and *S. mutans* showed markedly higher viabilities after the preacidification at pH 4.0 for 60 min, whereas the growth depression in acidic

conditions (pH 4.5–5.0) for *S. anginosus* was much lower than that for *S. mutans*. Both *S. anginosus* and *S. mutans* showed relatively higher ATPase activities than the other oral streptococci. However, the ADI activity was detected in *S. anginosus*, *S. sanguinis* and *S. gordonii*, but not in the other oral streptococci including *S. mutans*. Furthermore, the ADI activity in *S. anginosus* was the highest among the three.
Conclusion: Among oral streptococci, *S. anginosus* could have a significant aciduric property, which may be ascribable to their ATPase and ADI activities.

P1313 Investigation of affinity properties of receptor protein G of group G streptococci in different flow-through models using the approaches of affinity high-performance monolithic disk chromatography

O. Lozhkina, T. Gupalova, A. Totolian, T. Tennikova (St. Petersburg, RU)

Objectives: The in vitro study of surface proteins of pathogenic microorganisms in model systems imitating its natural microsurrounding allows to estimate the role of receptors in pathogenesis of bacteria. The aim of the present study was to develop several flow-through models with cell-imitators, intact and inactivated cells of Group G streptococci immobilised on CIM® monolithic stationary phases (BIA Separations, Slovenia) and to investigate them using the approaches of affinity high performance monolithic disk chromatography (AHPMDC) taking as a reference the interaction between surface protein G and human IgG, thoroughly studied before [1].
Methods: We developed and investigated four models of surface of *Streptococcus*: 1) cell-imitators on the base of monodisperse polymethylmethacrylate (PMMA) microspheres (1 mkm in diameter) with covalently attached recombinant protein G; 2) cell-imitators on the base of monodisperse PMMA microspheres functionalised with recombinant protein G and dextran, imitating polysaccharidic microsurrounding of the receptor protein, 3) inactivated cells of Group G streptococci (strain 148); 4) intact cells of Group G streptococci (strain 148). All models were covalently immobilised on the surface of flow-through pores of CIM® disks in order to examine such an affinity parameter as dissociation constant (Kdiss) of the interaction between protein G and human IgG by means of AHPMDC.
Results: Cell-imitators as well as cells themselves were immobilised on the surface of absolutely flow-through pores of monolithic sorbents and did not block them. Such a design of models allowed to realise the processes of elution at high speed (2.5 ml/min) in comparison to traditional affinity chromatography where average speed is about 1–2 ml/h. Kdiss evaluated for all the models described above were of the same magnitude, ranging around 10–6–10–7 M. These results are in good agreement with previously received data [1] and indicate that streptococcal protein G has an extremely high affinity to human IgG that does not depend on its microsurrounding and is not influenced by covalent immobilisation.
Conclusion: The developed methodical approach seems to be an attractive tool to study the interactions between human proteins and microorganisms in order to gain improved knowledge about the pathogenesis of the last ones.

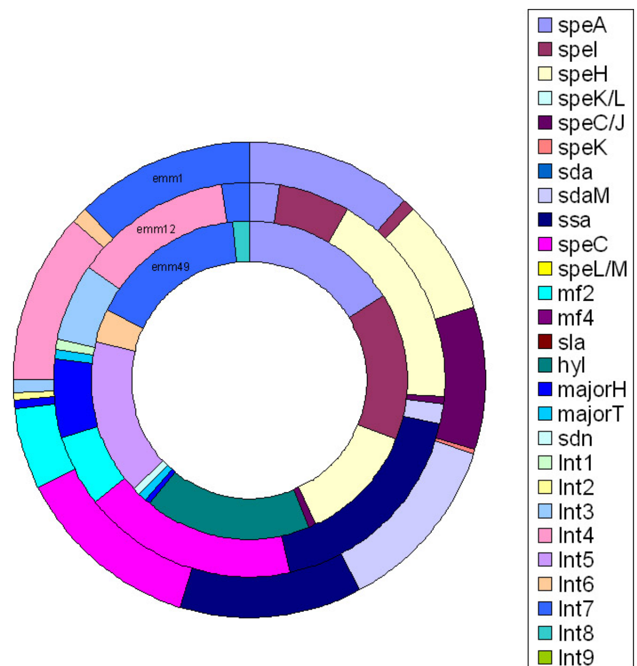
P1314 Bacteriophage genes distribution among GAS belonging to different M serotypes

E. Polyakova, W. Gao, A. Suvorov, Y. Yang, J. Ferretti, A. Totolian (St.Petersburg, RU; Bejing, CN; Oklahoma City, US)

Objectives: In spite of the intense use of antibiotics in medical practice, the group A streptococcus (GAS) continues to be one of the most common bacterial pathogens of humans. Recent sequencing information has shown that the GAS possess tremendous genetic variability and one of the reasons for this is the presence of numerous streptococcal bacteriophages, which often carry genes encoding toxins, mitogens, enzymes and antibiotic resistance factors. Little is known about the real impact of specific phage or phage transported virulence genes in GAS pathogenicity. The aim of the present work was to study a possible correlation between the specific M serotype of GAS and bacteriophage content.
Methods: 75 GAS strains belonging to serotypes M1, M12 and M49 (31, 22 and 22) were studied. *Streptococcus pyogenes* strains type M1 and M12 were obtained from Chinese patients with scarlet fever in Beijing during 2007. M49 strains known to be from patients with invasive disease were obtained from CDC in the USA and collected between 2000–2005. Strains were analysed by PCR with a panel of 27 pairs of primers corresponding to the genes of phage related virulence factors and a set of nine phage related integrases. Results were substantiated by microarray hybridisation.
Results: 75 GAS strains belonging to 3 different M serotypes were analysed by PCR. Among the GAS strains from serotype M49, the highly prevalent genes found were speA, speI, speH, int5 and int7. In M1 strains speA, speH, speC, speC/J, ssa, sdaM, int4 and int7 were determined. In M12 strains the prevalent genes were speH, ssa, speC and int4 (fig1). A distinct correlation was found between the M serotype of GAS under study and phage gene content suggesting that temperate bacteriophages might be an important factors in the development of epidemic strains and may be involved in the triggering of GAS infections.



Phage genes distribution.

Conclusions: PCR analysis of bacteriophage gene content in the epidemic GAS reveals that strains belonging to the same serotype have similar bacteriophage gene patterns. The role of the bacteriophages in GAS pathogenicity is discussed.

P1315 Horizontal transfer of the *E. faecalis* pathogenicity island between *E. faecalis* and *E. faecium*

J. Laverde-Gomez, C. Fleige, I. Klare, G. Werner (Wernigerode, DE)

Objectives: *E. faecalis* possesses a pathogenicity island (PAI) bearing the esp gene. In *E. faecium* a variant esp gene has been described and integration into a similar PAI structure is supposed. The data we

present here are to identify and characterise horizontal gene transfer of the *E. faecalis* PAI from *E. faecalis* to *E. faecium*.

Methods: Horizontal gene transfer was determined using a standard filter-mating procedure. Different donor and recipient stains (*E. faecium* 64/3; *E. faecalis* JH2–2, OG1RF) were tested. *E. faecium* transconjugants were checked for clonality with the recipient, i.a. by their PFGE patterns. Presence of esp was identified by PCR. PFGE, isolation of plasmid and genomic DNA were done according to standard procedures. Composition of the PAI was identified using single gene PCR, long PCR followed by restriction digestion and partly by DNA sequencing.

Results: While selecting for a transfer of erythromycin resistance between UW3114 and recipient 64/3 we were able to trigger parallel transfer of the esp gene. The donor and the esp-positive transconjugant possessed identical plasmids and plasmid digestion patterns suggesting chromosome to chromosome transfer of the esp/PAI from *E. faecalis* to *E. faecium*. We did PFGE with DNA from the donor, recipient, esp-positive and -negative transconjugants. Southern hybridisation identified a new 450 kb fragment possessing esp in the esp-positive transconjugant. Compared to the pattern of the recipient and the esp-negative transconjugant a 245 kb fragment disappeared in the PFGE pattern of the esp-positive transconjugant suggesting transfer of a ca. 205 (450–245) kb fragment bearing esp/PAI. Results of PCR and long PCR identified several deletions in the right end of the *E. faecalis* PAI in the donor and the esp-positive transconjugant.

Conclusions: In their original description, Shankar et al. (2002) were unable to transfer the newly described PAI in *E. faecalis*. However, by tagging the esp gene with a chloramphenicol marker Coburn et al. (2007) identified horizontal gene transfer of a 28 kb internal fragment of this PAI. We describe here for the first time inter-species transfer of the *E. faecalis* PAI into the genome of *E. faecium*. Our present data show transfer of a ca. 205 kb genomic fragment from *E. faecalis* bearing an incomplete but entire PAI element and integration of this fragment into the *E. faecium* genome.

P1316 Virulence factors and antimicrobial resistance in *H. pylori* clinical isolates by a multiple correspondence analysis

J.A. Garcia-Campos, T. Alarcon, D. Domingo, M. Lopez-Brea (Madrid, ES)

The aim of this study was to determine the presence of different virulence factors and antimicrobial resistance in *H. pylori* clinical isolates and to analyse the results obtained by a multiple correspondence analysis (MCA).

Methods: 70 *H. pylori* strains were obtained from patients attending to the Gastroenterology Unit due to different symptomatology. 46 out of the 75 suffered of gastritis and 29 of peptic ulcer. Upper endoscopy was performed and biopsy cultured following standard methodology. DNA was extracted from a 48 h culture and PCR performed to detect cagA gene, vacA s1- and s2-alleles, babA2 gene, hpaA alleles and hopQ alleles. Specific primers for the cag empty site were also used to confirm the absence of the cagPAI (ES-cagA). All PCR products were analysed by agarose gel stained with ethidium bromide. Lewis antigen was determined by an Enzimoimmuno assay using monoclonal anti-LewisX and anti-LewisY and alcaline phosphatase labelled secondary antidodies. Metronidazole and clarithromycin resistance was determined by E-test.

Results: Three groups were detected by MCA: (1) strains positive for cagA gene (non discrepant with ES-cagA), vacAs1, hopQ type I-II, negative for babA2 and clarithromycin and metronidazole susceptible (group A). (2) Strains negative for cagA (discrepant with ES-cagA) and positive for vacAs2, hopQ type II, babA2, hpaA2, clarithromycin and metronidazole resistant and expressing Lewis antigen (LeXY or LeY) (group B). (3) A heterogeneous group (group C). Same results were detected when a dendogram for cluster analysis was drawn.

When the MCA analysis was performed in strains form ulcer patients the same 3 groups were detected with small differences. In strains from gastritis higher differences were found. cagA+, vacAs1, hpaA1 and hopQ I-II strains were associated with clarithromycin and metronidazole resistance (in ulcer strains were associated with susceptible ones), the presence of babA2, the expression of LewisXY antigen and the discrepancies with ES-cagA.

Conclusions: Strains with more virulence factors grouped together when MCA was performed. Moreover, in strains from gastritis virulence genes were associated with clarithromycin and metronidazole resistance whilst in ulcer strains they were associated with susceptible ones.

P1317 Relevance of human beta defensin-1 in *Helicobacter pylori*-induced gastritis

K.A. Kocsis, Z. Kiss, F. Somogyvári, Z. Tiszlavitz, D. Szoke, Y. Mándi (Szeged, Budapest, HU)

Objectives: Human beta defensins (HBDs) are antimicrobial peptides that are expressed by epithelia on mucosal surfaces. Recent reports have demonstrated that *Helicobacter pylori* infection induces HBD-2, whereas HBD-1 is thought to be expressed constitutively, and it's role in *H. pylori* infection is controversal. Therefore, the aim of the present study was to investigate the relevance of three SNPs of the HBD-1 gene in *H. pylori* induced chronic gastritis. We have also assessed mRNA expression of human beta-defensin 1 in by *H. pylori* infected AGS cells.

Methods: Three SNPs of the DEFB1 gene DEFB1 G-20A (rs11362), DEFB1 C-44G (rs1800972) and DEFB1 G-52A (rs1799946) were genotyped either by Custom TaqMan® SNP Genotyping Assays or by restriction fragment length polymorphisms (RFLP) in 150 patients with chronic active gastritis. Patients were examined by gastroduodenoscopy. HP positivity was detected by 13C-UBT and hystopathology. 100 serologically *H. pylori*-positive subjects without gastric or duodenal symptoms served as controls. Human beta-defensin1 mRNA expression in AGS cells was measured by quantitative RT-PCR reaction

Results: No significant difference was observed in the case of investigation the DEFB-1 SNPs at the region of −22 and −44. A definitive differences in the frequency of GA and AA genotypes of G-52 A SNP was observed between patients with gastritis and healthy controls. Conversely, the wild type genotype (GG) was significantly more frequent (47%) among healthy subjects than in patients (29%).

A dose dependent increase in HBD1 mRNA was observed in AGS cell line following infection with increasing number of *H. pylori*

Conclusion: We suppose, that the SNP in the −52 untranslated region of HBD-1 might be connected with a deficient function of human β defensin. This could lead to an increased colonisation of *H. pylori* in the stomac, with an ineffective clearence, and a consequent inflammation. Considering the results of the genetic and in vitro experiments our results draw the attention that not only the inducible, but also the constitutive form of human beta defensin have importance in pathogenesis of *H. pylori* induced gastritis.

P1318 Polymorphisms in the NOD1 and IL-8 gene, but not in the TLR4 gene are associated with *Helicobacter pylori*-induced duodenal ulcer and gastritis

Y. Mándi, P. Hofner, Z. Kiss, A. Tiszai, Z. Tiszlavitz, B. Molnár, Z. Tulassay (Szeged, Budapest, HU)

Objectives: Intracellular pathogen receptor NOD1 is involved in the epithelial cell sensing *Helicobacter pylori*, which results in a considerable interleukin (IL-8) production. The aim of this study was to evaluate the relationship between NOD1 and IL-8 genetic polymorphisms and the development of *H. pylori*-induced gastritis and duodenal ulcer (DU), as compared with TLR4 polymorphisms.

Methods: Eighty-five patients with DU and 135 patients with gastritis were enrolled in the study. Patients were examined by gastroduodenoscopy. HP positivity was detected by 13C-UBT and hystopathology. Seventy-five serologically *H. pylori*-positive subjects without gastric or duodenal symptoms served as controls. The G796A (E266K) NOD1 polymorphism was determined by restriction fragment length polymorphism, and the −251 IL-8 polymorphism by amplification

refractory mutation system method. The TLR4 (ASP/299/Gly and Thr/399/Ile) gene polymorphisms were examined by melting point analysis.

Results: AA homozygote mutant variants of NOD1 were detected in 20% of the *H. pylori*-positive patients with DU versus 7% of *H. pylori*-positive patients with gastritis and versus 6% of the *H. pylori*-positive healthy controls. The IL-8 heterozygote mutant variant was detected with a significantly higher frequency among the DU patients (57.6%) and those with gastritis (55.9%) than among the *H. pylori*-positive controls (40%). However, no significant correlation concerning the frequency of the TLR4 gene polymorphism could be revealed between any group of patients and the controls.

Conclusions: E266K CARD4/NOD1, but not the TLR4 gene polymorphism increases the risk of peptic ulceration in *H. pylori*-positive patients. The −251 IL-8 polymorphism was significantly associated with either gastritis or DU in *H. pylori*-infected subjects. Host factors including intracellular pathogen receptors and IL-8 production play an important role in *H. pylori*-induced gastric mucosal damage.

P1319 Intestinal Oxalobacter formigenes colonisation in children with calcium oxalate urolithiasis. A study from southeastern Poland.

P. Sikora, J. Niedzwiadek, E. Mazur, A. Niedzwiadek, M. Zajaczkowska, M. Koziol-Montewka (Lublin, PL)

Objective: Oxalobacter formigenes is an obligate anaerobic Gram-negative bacterium colonising the colon of vertebrates, including humans. This organism utilises oxalate as the only source of carbon and therefore participates in oxalic acid homeostasis. In adults, it was suggested that the lack of colonisation with O. formigenes may lead to the intestinal oxalate hyperabsorption and to calcium oxalate urolithiasis (CaOxU) as a consequence. To our knowledge this problem was not investigated in paediatric population. Hence, the aim of our study was the assessment of O. formigenes colonisation rate in children with CaOxU.

Methods: DNA was extracted from the frozen faecal samples of 84 children and adolescents (41 boys, 43 girls) aged 4.9–17.6 years with CaOxU and 63 healthy, age- and gender matched subjects. Identification of O. formigenes was performed by polymerase chain reaction (PCR) using genus specific primers, according to Sidhu et al. (JCM 1999, 37, 1503–1509).

Results: O. formigenes was found in 23.8% (20/84) of patients with CaOxU and in 20.6% (13/63) of healthy controls.

Conclusions: In contrast to adults, we did not find any significant difference in O. formigenes colonisation rate between individuals with or without urolithiasis. However, an absence of O. formigenes in majority of children from both groups requires further explanation. It could be caused by an overuse of antibiotics in our region. Also, we can not exclude that extreme variability in the O. formigenes content of stool samples among individuals may be responsible for the low rate of O. formigenes identification in both examined groups.

The research was supported by the Polish State Committee for Scientific Research (KBN grant 2P05D 117 26).

Antibacterial vaccines

P1320 Analysis of *Haemophilus influenzae* isolated from invasive disease, in Portugal, during extensive vaccination against *H. influenzae* serotype b

P. Bajanca, D. Louro, M. Caniça on behalf of ARSIP (Antibiotic Resistance Surveillance Programme in Portugal)

Background: *Haemophilus influenzae* (Hi), an exclusively human pathogen is responsible for potentially life threatening invasive disease such as meningitis and septicaemia. Hi pathogenicity varies depending on the presence or absence of a capsule and the specific capsule type. Hi serotype b (Hib) vaccine was adopted in Portugal since 1994 and obligated since the year 2000 to children less than five years old. In vaccine era, non capsulated (NC) isolates have become the most common cause of invasive Hi disease in all age groups.

Objectives: We pretend to analyse Hi serotypes as well as antimicrobial susceptibility changes in the vaccine era and compare with previous studies in Portugal.

Methods: We collected 102 invasive isolates (20 CSF, 74 blood cultures and 8 pleural fluids), from 2000 to 2007, in Antibiotic Resistance Unit from the National Institute of Health, from several Hospital Laboratories in different regions of Portugal.

Identification of Hi was confirmed by standard procedures. Nitrocefin was used to determine β-lactamase production. Susceptibility testing was performed by micro dilution, according to the CLSI guidelines. Serotyping was performed by PCR.

Results: Strains were distributed by age as follow: forty-one strains (40.2%) were from children (<18 years old), being twenty eight of these (68.3%) from under 5 years old; fifty-nine strains (57.8%) were isolated from adults.

From all the invasive strains, 10.8% were β-lactamase producers and 5.5% with MIC values to ampicillin and clavulanic acid of 2 mg/L, were considered ampicillin-resistance-non-β-lactamase-producers (ARNBLP). Resistance to SXT was high: 19%.

As we expected, most strains (76.5%) were NC, being 15 of serotype b (15.3%).

Two of the 3 serotype a strains, were isolated from children. All 4 serotype f strains and 1 serotype d were from adults.

In a previous study of invasive strains, performed in our laboratory with strains isolated between 1989 and 2001, we observed a decline in serotype b strains, from 81% to 16%, accompanied by an increase of NC strains, from 19% to 80%.

Conclusions: This study continues to documents changes in invasive infections following the introduction of the vaccine in Portugal. We are assisting to an increment of NC strains as well as a great decline of Hi serotype b.

We also expect an increase of non-b-type strains in Hi invasive disease and a new rule in the virulence of these strains. So, it's imperative to continue this kind of studies.

P1321 Changes in invasive pneumococcal disease among children after the introduction of the heptavalent pneumococcal conjugate vaccine

M. Gimenez, M. Eril, S. Molinos, M. Azuara, C. Rodrigo, V. Ausina (Badalona, ES)

Objectives: Pneumococcal conjugate vaccine (PVC-7) has been reported to prevent invasive disease (IPD) by covering the most prevalent serotypes isolated from blood or CSF. Implementation of PCV-7 could have changed epidemiology, clinical and analytical features of IPD. We analysed the impact of PCV-7 in our community, focusing on emergence of nonvaccine serogrups, clinical diagnosis, incidence of empyema and inflammatory response (C-reactive protein [CRP], procalcitonin [PCT]).

Methods: we analysed 75 episodes of bacteraemia within two periods, from 1995 to 2001 (prelicensure period) and from 2002 to September 2007 (postlicensure) in children below 18 years old admitted in the Department of Paediatrics of a tertiary-care Hospital of Barcelona.

Results: A total of 76 children with pneumococcal bacteraemia were identified, with 28 episodes occurring in the prelicensure period and 48 in the postlicensure period. Forty-two (42.1%) were <2 years old, 39.5% were between 2 and 5 years old and 18.4% were >5 years old. Respiratory (60.5%), occult bacteraemia (15.8%), sepsis without focus (11.8%) and meningitis (7.9%) were the most frequent clinical manifestations, without statistical differences between the two periods. There was a trend towards increasing frequency of respiratory focus during the second period but changes in incidence of non-vaccine serotypes were not statistically significant. Serotypes 1 and 14 accounted for 44% of all isolates vs 29% in the pre-licensure period. Serotype 1 was significantly associated with empyema, increased CRP and PCT values, and length of hospitalisation (14±4 days). Serotypes 1 (4 cases), 15B, 19A and 24 caused IPD in 7 vaccinated children. High resistant

penicillin strains showed an increase from 17.9% to 25% and eritromycin from 21.4% to 31.3%, between the pre and postlicensure period.
Conclusions: We found an increased number of empyema cases caused by serotype 1, with high CRP and PCT during the postlicensure period. Changes towards the emergence of non-vaccine serotypes causing IPD are not significant in our area. We didn't find vaccinated children with IPD caused by serotypes included in PCV-7.

P1322 Knowledge of healthcare workers regarding occupational vaccinations

P. Loulergue, Z. Absi, C. Demontpion, F. Moulin, C. Menager, M. Gorodetzky, G. Vidal-Trecan, D. Gendrel, L. Guillevin, O. Launay (Paris, FR)

Immunisation against diphteria, tetanus, poliomyelitis, hepatitis B and tuberculosis are mandatory for healthcare workers (HCW) in France. The Committee for Public Health (Haut Conseil de la Santé Publique) also strongly recommends immunisations against influenza, pertussis, varicella, measles and for non immunised HCW.
Objectives: To evaluate the knowledge of hospital HCW regarding mandatory or recommended vaccinations.
Methods: We performed a cross-sectional survey in two medical departments: one in an internal medicine department caring for immunosuppressed patients, and one in a paediatric department. A self-administered questionnaire was used to assess all the medical and non medical staff (physicians, students, nurses, paramedics and staff not caring for patients) knowledge regarding mandatory and recommended vaccinations, their current vaccination status and potential reasons for refusal of vaccine uptake.
Results: Three hundred and ninety-five questionnaires were analysed (280 from the Internal medicine and 115 from paediatric departments). Although 95% of the staff declared a good knowledge of the compulsory vaccination, only 20.7% of the internal medicine staff and 30.6% of the paediatric staff could cite them correctly ($p=0.05$). More than 70% declared knowing the recommended vaccinations: 68% cited influenza, 15.4%, pertussis, 5.7% measlesand 4.7%, varicella.
The overall influenza vaccination rate in 2006 was higher in paediatrics than in internal medicine unit (36% vs. 28%; $p=0.012$); 50% of the physicians, 42.7% of the students and 22.6% of the nursing staff received influenza vaccine. The strongest motivations for having received influenza vaccination were to protect patients (73%) and to protect oneself (67%). Contrarily, the main reasons for vaccination refusal were believing the vaccine to be inefficacious (53%) and fearing adverse effects (21%). Reasons for not having been vaccined against influenza may differ between nursing/paramedical staff and physician staff.
Conclusion: Knowledge about vaccinations is poor among HCW. Despite recommendations for annual influenza vaccination, the proportion of HCW vaccinated is still insufficient, mainly due to a misperception of the efficacy of the influenza vaccination. This study highlights the need to strengthen continuous education of HCW regarding vaccinations.

P1323 Serotype distribution of *Haemophilus influenzae* isolates from post-vaccinated Mexican children: comparison between antisera and PCR-based typing methods

R. Gonzaga, J. Diaz Garcia, A. Alfaro, A. Villaseñor Sierra, R. Gracia, J. Santos, P. Gomez de Leon (Mexico City, Guadalajara, Puebla, MX)

Objective: The world wide use of *Haemophilus influenzae* (Hi) type b conjugate vaccine has resulted in a significant decline in the incidence of invasive disease in children <5 years of age. The 3 doses scheme of polyribosyl ribitol phosphate (PRP)-T was licensed in our country in 1999. However it has been speculated that this may lead to a greater prevalence of nonencapsulated (NE) and encapsulated non-b strains. Surveillance studies are increasingly important in Mexico for monitoring the emergence of such strains. In this study we compare the serotype distribution of post-vaccine Hi isolates using PCR-based serotyping method to that obtained by slide agglutination serotyping (SAS), currently considered as the gold standard.
Methods: One hundred and eleven Hi strains were screened by the SAS method using polyvalent and monovalent antisera. A PCR assay for the bexA locus was used to detect encapsulated strains. The encapsulated isolates were genotyped using serotype-specific primers for the a, b, e, and f Hi types.
Results: In this study, the SAS method revealed 88 (79.3%) NE Hi strains, of which 6 were found to be types a (1), f (4) and e (1) when the PCR capsule genotyping was performed. Additional discrepancies were observed when 7 NE isolates detected by the PCR method were misidentified as serotypes b (6) and f (1) by SAS. The overall 7.2% (8/111) of the strains contained the f serotype-specific sequence. There was 11.7% discrepancy between the SAS and the PCR-based genotyping methods.
Conclusions: The data showed that Hi serotype f is circulating among post-vaccinated Mexican children. The gold standard method for serotyping the Hi strains still offers equivocal results. The genotyping PCR assay provides a more accurate alternative for determining Hi serotypes.

P1324 Immunological responses to BCG vaccination in *Mycobacterium bovis*-challenged cattle

J. Witchell, M. Vordermeier, A. Wangoo, M. Goyal (Hatfield, Addlestone, UK)

Objectives: BCG vaccination studies in cattle have shown extreme variability in protection against *Mycobacterium bovis* infection. A critical first step in the development of an improved vaccination is the understanding of the host immune response to infection and vaccination.
Methods: This study focused on four experimental cattle groups BCG Pasteur vaccinated *M. bovis* challenged, BCG vaccinated non challenged, non vaccinated *M. bovis* challenged and non vaccinated non challenged. mRNA expression levels of IFN gamma, TNF alpha, IL10 and IL4 were measured within thoracic lymph nodes of each animal using quantitative real time PCR. Protein levels of IFN gamma and TNF alpha were measured within each lymph node using immunohistochemistry.
Results: Challenge with *M. bovis* significantly increased IFN gamma mRNA levels (94%), reduced IL10 mRNA levels (56%) and suppressed IL4 mRNA expression completely. There was a significant increase in IFN gamma protein levels (on a score scale of 1–4, challenged animals averaged at 2.75 compared to non-challenged at 1.3) however TNF alpha mRNA and protein levels were not significantly affected by *M. bovis* challenge. BCG vaccination prior to challenge reduced the level of IFN gamma mRNA (81%) and IFN gamma protein (averaged score of 1.5) as compared to the non vaccinated challenged cattle. BCG vaccination without challenge appeared to have no effect on the cytokine and protein levels however IL4 mRNA was detectable. There was a strong positive correlation between IFN gamma mRNA and IFN gamma protein levels but no correlation was observed between TNF alpha mRNA and TNF alpha protein.
Conclusion: *M. bovis* infection activates a strong cell mediated immune response signified by the dramatic increase in IFN gamma mRNA expression. Subsequently IFN gamma protein levels increased leading to a strong T helper (TH) class 1 profile with the related reduction of IL10 and IL4 mRNA expression.
Cattle vaccinated with BCG before challenge showed an increase in IFN gamma mRNA expression but to a lesser degree as compared to non vaccinated animals due to the primed immune response. The IL10 mRNA levels were not significantly reduced in vaccinated animals and so dampened the pro-inflammatory response producing a lower level of pathology within the vaccinated animals. Finally, it appears that IL10 mRNA may experience post transcriptional regulation due to the absence of a correlation between mRNA and protein levels.

P1325 REPEVAX® can be safely administered as a booster one month after tetanus, diphtheria and poliomyelitis vaccination: an option for managing increasing incidence of Bordetella pertussis (whooping cough) infection

J. Beytout, O. Launay, C. Dubray, F. Galtier, C. Noize-Pin, N. Guiso, M. Baudin, P. Richard, C. Tran, E. Ledesma, A. Fiquet, C. Baptiste, B. Soubeyrand (Clermont Ferrand, Paris, Montpellier, Villeurbanne, Lyon, FR)

Objectives: In France it is recommended to administer a booster dose of a pertussis-containing vaccine in adults which can result in them receiving 2 doses of tetanus (T) and/or diphtheria (D/d) and/or poliomyelitis (inactivated, IPV) containing vaccine within a short period (eg catch-up programme or pertussis outbreak). In children and teenagers it has been shown that boosters can be safely given with intervals as short as about 2 years, but in adults there are no data for intervals less than 5 years. We assessed the safety of a booster dose of a pertussis-containing vaccine (acellular component, aP) shortly after a Td-IPV booster.
Methods: 500 healthy adults 18–40 years, having received ⩾5 doses of T, D and poliomyelitis vaccine by the age of 18, with the last dose of T and/or D and/or poliomyelitis vaccine given alone or combined at least 5 years previously, were randomised to receive either Td-IPV (REVAXIS®; Group 1) or placebo (Group 2) followed by Td5aP-IPV (REPEVAX®) in both groups one month later in a double-blind trial. Adverse events, including pre-listed events for the first 7 days (injection-site erythema, swelling, and pain, oral temperature ⩾37.5°C, headache and myalgia) were recorded on a diary card.
Results: The groups were similar in terms of age, sex ratio, weight, height, number of previous vaccinations with D, T, and poliomyelitis and intervals between last D, T or poliomyelitis vaccination and study start. 484 subjects who received the second injection were included in the REPEVAX® safety analysis. The adverse event rates reported after REPEVAX® were similar in both groups except for a lower incidence of solicited injection-site reactions in subjects in Group 1.
In Group 1 the rates of injection-site swelling and pain reported within 7 days after REPEVAX® were lower than in Group 2 (19.4% vs 27.7% and 82.6% vs 92.1%, respectively). The confidence interval of the difference between groups did not include 0 (swelling: –8.3 [–15.7; –0.7], pain: –9.5 [–15.5; –3.6]), but this was not judged to be clinically meaningful.

Adverse events	Group 1, % (n = 242)	Group 2, % (n = 242)
Pre-listed (Day 0–7)		
Injection-site reactions	84.3	93.0
Systemic adverse events	36.0	37.6
Spontaneously reported (Day 0–14)		
Injection-site reactions	14.9	16.1
Systemic adverse events	20.2	19.0

Conclusion: These data support the use of REPEVAX® in adults, even one month after a booster with Td-IPV. REPEVAX® can be used as a booster to reduce the incidence of whooping cough.

P1326 Elaboration of a type three secretion system-based *Pseudomonas aeruginosa* live vector for immunotherapy purposes

O. Epaulard, M. Guillaume, M. Derouazi, J. Franetich, A.C. Bretz, B. Polack, D. Mazier, P.N. Marche, B. Toussaint (Grenoble, Paris, FR)

Objectives: Numerous immunotherapy methods have been designed to eliminate cell populations (infected or tumour cells). To trigger an efficient cytotoxic T lymphocyte (CTL)-based response, the target antigen (Ag) (i.e., viral protein) must 1) be delivered to dendritic cell (DC) in order to obtain an MHC-I restricted presentation and a subsequent CTL activation, and 2) be associated with a danger signal in order to activate DC. We took advantage of *Pseudomonas aeruginosa* type three secretion system (TTSS) to elaborate a bacterial immunotherapy live vector. TTSS is used by Gram-negative rods to inject protein effectors inside target cells such as (for *P. aeruginosa*) dendritic cells and PMN. A TTSS-based live vector would ensure both danger signal and delivery of Ag to DC.
Methods and Results: By fusing different eukaryotic proteins with a non-toxic fragment of a TTSS effector, we obtained the secretion by *P. aeruginosa* TTSS of these fusion proteins. Ovalbumin was first used as a model antigen. In vitro, murine dendritic cells having incubated with the ovalbumin-delivering vector were able to activate specific anti-ovalbumin CTL. In vivo, after 2 injections of 5.10e6 ovalbumin-delivering bacteria, mice generated anti-ovalbumin CTL. The efficiency of this response was assessed by injecting ovalbumin-expressing syngenic melanoma cells to these mice; we obtain a complete protection (no tumour onset) of 7/8 animals, but no protection in animals injected with a vector delivering a control Ag. A significant but less vigorous protection was observed when the vector delivered a native Ag of melanoma.
The bacteria had been already attenuated by deleting the genes of TTSS effectors ExoS and ExoT. Virulence was further altered by deleting central genes of quorum sensing (coding for synthases LasI and RhlI) and/or gene aroA (rendering the bacteria auxotrophic for aromatic amino-acids). The maximally attenuated vector had a LD50 more than 100 times higher and a conserved efficiency as immunotherapy vector.
We explored another model by vectorising *Plasmodium yoelii* circumsporozoite protein as to target infection at the liver stage. We observed a significantly delayed blood smear positivation after sporozoite infection in vaccinated mouse, indicating that the immune response triggered by the vector was partly efficient.
Conclusion: We believe that this TTSS-based *P. aeruginosa* vector is a promising immunotherapy tool in both infectious and tumour diseases.

P1327 The application of *Neisseria meningitidis* serogroup B outer membrane vesicle as an adjuvant to induce specific antibody against the LPS of *Brucella abortus* S-99 in animal model

S.D. Siadat, D. Norouzian, A. Sharifat Salmani, H. Ahmadi, M. Nejati, M. Kheirandish, M. Zangeneh, M.H. Hedayati, A. Moshiri, S.S. Siadat, S. Shokohi, M. Karbasian, M. Salimi (Tehran, IR)

Objective: Smoth lipopolysaccharide(S-LPS)of *Brucella abortus* can be candidated as a potent human vaccine. The adjuvants with microbial origins are more considerable among the other current adjuvants nowadays. The outer membrane vesicle(OMV)of *Neisseria meningitidis* serogroup B is one of the newly studied adjuvants with microbial origin.
Methods: The S-LPS of *Brucella* was extracted by Hot phenol-water with some modification as described previously. The noncovalent complex of S-LPS-OMV was injected subcutaneously into groups of ten mice with boosters on days 14 and 28 after the primary immunisation. The following groups were used as control: 1-LPS, 2-LPS plus incomplete Freunds adjuvan(IFA)and 3-LPS plus Freund's complete adjuvant (CFA). The mice were bled on days 0, 14, 28, 42.The humoral immune responses evaluated by detection of specific anti-LPS IgM and IgG titre via ELISA method.
Results: Anti-LPS IgG titre(demonstrated by ELISA)for LPS plus OMV has been increased 3.9, 3.18 and 1.58 fold after 14 days in comparison with the LPS, LPS plus IFA and LPS plus CFA control group. The application of LPS plus CFA led to higher level anti-LPS IgG titre than LPS plus IFA and LPS with 1.98 and 2.5 fold, respectively. The anti-LPS IgG titre in LPS plus IFA control group was not significantly increased in comparison with the LPS group. Booster doses have been effective to significantly increase anti-LPS IgG titre in all groups after 28 days. An increase in anti-LPS IgG titre following the second and third dose of LPS plus OMV induced 6 and 12.4 fold titres in comparison with the first dose. The highest anti-LPS IgG titre detected two weeks after the third dose(after 42 days)of LPS plus OMV.Comparative study of anti-LPS IgM titres were not revealed any significant level in all groups.

Conclusion: In this study, we showed that *N. meningitidis* serogroup B OMV in noncovalent complex with *Brucella abortus* S99 LPS induces high level of anti-LPS IgG and our purified OMV could act as an effective adjuvant. Since the application of most adjuvants is restricted because of hypersensitivity reactions and the safety of OMV in humans has been demonstrated in many studies, OMV would be a safe adjuvant which does not cause hypersensitivity and DTH reactions. Therefore noncovalent complex of OMV-*B. abortus* LPS may be a candidate for further development as a brucellosis vaccine for human use.

P1328 Immunological evaluation of vi-vapsular polysaccharide of *Salmonella typhi* vaccine by serum bactericidal assay

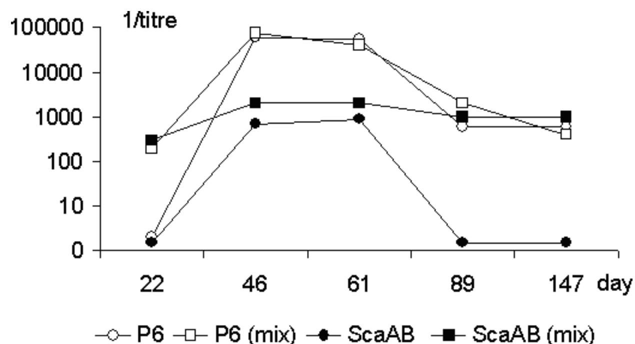
H. Ahmadi, B. Tabaraiee, S.D. Siadat, F. Poor mirza gholi, D. Norouzian, M. Nejati, M.H. Hedayati, K. Mahmoodi, A. Sharifat Salmani, M. Abbasi, M. Karbasian, A. Adli Moghadam (Tehran, IR)

Objectives: *Salmonella typhi* Vi-capsular polysaccharide (Vi-CPS) is an essential virulence factor and a safe and reliable vaccine against typhoid fever (Acharya et al, 1975: Szu et al, 1994: Yang et al, 2001). Since there is no any animal model for *Salmonella typhi* fever to evaluate protective efficacy of Vi-CPS vaccine, we recommend, serum bactericidal assay (SBA) as a golden standard to evaluate its potency.
Methods: Vi-CPS was extracted from *Salmonella typhi* Ty6S (CSBPI-B-191) according to the modified Gotschlich method (Ahmadi et al, 1999). Fifty μg of purified Vi-CPS was injected intramuscularly into three groups of five rabbits, Groups 2 and 3 were received additional booster dose of 50 μg Vi-CPS on day 15 and days 15 and 30 respectively. Each group of pooled serum was tested by SBA on days 0, 15, 30 and 45.
Results: The titers of SBA of anti Vi-CPS were 4, 16 and 16 for group 1 and 4, 32 and 32 for group 2 and 16, 64 and 64 for group 3 in days 15, 30 and 45 respectively.
Our investigation reveals that; Vi-CPS is a potent immunogen. Because, at even one does of 50 μg, could show an excellent bactericidal effect against pathogenic *Salmonella typhi*.
Conclusions: Though Vi-CPS is a reliable vaccine against typhoid fever but sometimes depolymerisation take place during purification and may cause low potency. This draw back can be resolved through potency test. Since passive hemaglutination test recommended by WHO., does not indicate potency of the vaccine, we recommend SBA method to evaluate the ability of Vi-CPS to kill pathogenic *Salmonella typhi*, as it has been shown in our present results.

P1329 Constraction of polyvalent anti-streptococcal vaccines and analysis of their polyvalent features

L.F. Meringova, M.A. Ditina, A. Wang, G.F. Leontieva, K.B. Grabovskaya, X.Z. Shen, Y.H. Yang, A.A. Totolian, A.N. Suvorov (St-Petersburg, RU; Beijing, CN)

Objectives: In many occasions when antibiotic prophylactics fails vaccination becomes the matter of choice. More studies have been made for streptococcal vaccine development. The most common approach for streptococcal vaccine generation is based on the obtaining the conjugates between the polyvalent protein antigens and polysaccharide capsule. This strategy provides both an immunogenicity, with significant protection and broad level of type specificity. The present work presents data on comparison of two variants of vaccines: one based on mixture of recombinant proteins and another on the conjugation of type III GBS (PS) capsular polysaccharide with GBS recombinant cell surface polypeptides.
Methods: Conjugation of polypeptides with PS was obtained by reductive amination. Immune response had been studied in mice (double immunisation with aluminum hydroxide as adjuvant). Antibody titer was tested by ELISA. Biological activity of antibodies was tested by opsonophagocytosis employing mice peritoneal macrophages.
Results: After optimisation of PS-peptides conjugation conditions (optimal concentration of the components, oxidation time, the temperature of reaction etc.) the best chemical reaction conditions for two of the recombinant polypeptides under study (P6 and ScaAB) were found. Vaccine preparations containing P6-PS or ScaAB-PS reacted with antibodies against each of the vaccine components which proved that the antigenic structure had been preserved. Covalent binding of the PS to P6 or ScaAB lead to the four fold increase of the immune response relatively mono peptides usage with maximum titers against P6 and ScaAB 1/13000 or 1/104000 concordantly. PS after the binding also was immunogenic which was proved by appearance of specific IgG which were detected up till 70 days after the immunisation. In case of the mixture of the peptides P6 and ScaAB the titer of specific antibodies against ScaAB-components was also increased as well as length of the antibody circulation – 150 days. Mice antibodies obtained after immunisation with both type of vaccines were active against GBS belonging to different serotypes.



P6- and ScaAB-specific immune response (mixt vaccine and free form immunisation).

Conclusion: Usage of polyvalent vaccine preparations based on cell surface expressed recombinant polypeptides of GBS can dramatically increase their immunological features relatively to monovaccines.

P1330 TSA gene of *Leishmania major* cloned in eukaryotic expression vector could stimulated immune system in mice

F. Ghaffarifar, F. Tabatabaie, Z. Sharifi, A. Dalimi Asl, S. Ghasemi, M. Ghafarifar (Tehran, IR)

Objectives: TSA (thiol-specific-antioxidant antigen) is the immunodominant antigen of *Leishmania major* considered as the most promising molecule for a recombinant or DNA vaccine candidate against leishmaniasis. In the present work.
Methods: Genomic DNA of TSA protein was extracted and amplificated as a template. The PCR product has cloned into pTZ57R/T vector followed by subcloning into the eukaryotic expression vector pcDNA3 (EcoRI and HindIII sites). The expression of plasmid containing TSA gene was demonstrated by SDS-PAGE and Western-blot. These results indicated successful expression of plasmid containing TSA gene in eukaryotic cells.
Results: In the present study, we evaluated TSA-encoded DNA vaccine against *L. major* in BALB/C mice. IgG and IFN-g values were markedly increased in the immunised group, which were significantly higher than in the control groups ($p < 0.05$) following immunisation and after challenge with *Leishmania major*. IL-4 values were increased in all groups, but there was no statistical difference between the groups ($p > 0.05$) following immunisation and after challenge with *Leishmania major*.
Conclusion: The findings of this study indicated that the TSA-encoded DNA vaccine increased the cellular response and induced protection against infection with *Leishmania* in the mice. The TSA-encoded DNA vaccine may be an excellent candidate for future vaccine developments against *Leishmania*.

P1331 Diversity of pneumococcal surface protein A among prevalent clones causing invasive disease in adult patients in Barcelona (1997–2006)

D. Rolo, C. Ardanuy, R. Martín, J. Liñares (Barcelona, ES)

Objectives: Pneumococcal surface protein A (PspA) is a recognised major virulence factor and it has been classified into family 1 (Fam1: clades 1 and 2), family 2 (Fam2: clades 3, 4 and 5), and family 3 (Fam3: clade 6). After PCV7 vaccination, serotype/clone replacement has been observed worldwide. The aim of this study was to determine the distribution of Fam and clade of PspA among invasive representative *S. pneumoniae* (Spn) strains from adult patients from the Hospital Universitari de Bellvitge, Barcelona, in order to establish the possible use of PspA as a vaccine candidate.
Methods: In our Hospital, 90% (n = 395) of the invasive pneumococci isolated from adult patients from 1997 to 2006 were studied by PFGE (SmaI) and serotyping. A total of 72% of the studied strains were grouped into 28 major PFGE patterns. A selection of 49 invasive pneumococci, representative of those dominant PFGE patterns, was characterised by MLST (ST) and PspA. Clade-defining region of PspA was amplified by PCR, sequenced and compared with published data.
Results: PspA sequence analysis revealed that 30 strains belonged to Fam2, 18 strains to Fam1 and one strain was non-typeable. No Fam3 strains were detected. Association between serotypes and Fam/clade was not found, however a relationship between Fam/clade and ST was observed:
– Fam1/clade1 (n = 37) was associated with Spain6B-2, Spain14–5, England14–9, Colombia5–19, Sweden1–28, Sweden1–40, Netherlands8–33, ST97-serotype 10, ST1026-serotype 20, ST311-serotype 23F and ST433-serotype 22 clones
– Fam1/clade2 (n = 3) was associated with ST2217-serotype 35F clone
– Fam2/clade3 (n = 39) was associated with Spain23F-1, Spain9V-3, Netherlands3–31, Netherlands7F-39, ST110-serotype 18C, ST62-serotype 11A, ST202-serotype 19A, ST247-serotype 4, ST30-serotype 16, ST67-serotype 9N and ST88-serotype 19F clones
– Fam2/clade4 (n = 3) was associated with Sweden15A-25, Netherlands18C-36, ST42-serotype 23A, ST2312-serotype 8 and ST558-serotype 35B clones
– Fam2/clade5 (n = 3) was associated with Poland6B-20, ST260-serotype 3 and ST989-serotype 12 clones.
Conclusions: A clear association between PspA (Fam/clade) and genotype (ST) was found, whereas PspA (Fam/clade) was independent of serotype. The most important Fam/clades of PspA among invasive pneumococci isolated from adult patients in our geographical area were Fam2/clade3 and Fam1/clade1. Since international clones contain PspA Fam1 and Fam2, both families should be included in a future PspA based vaccine.

P1332 Comparative analysis of Bordetella pertussis strains included in the Serbian whole-cell vaccine

T. Pljesa, A. Elomaa, G. Dakic, M. Vignjevic-Krastavcevic, Q. He (Belgrade, RS; Turku, FI)

Objectives: In Europe, countries use different vaccination strategies against pertussis. In Serbia, vaccination against pertussis has been in use for 50 years. The whole-cell pertussis vaccine has been manufactured in the Torlak Institute, Belgrade, Serbia since 1957.
The vaccine is made of autochthonous Bordetella pertussis strains, and "new" strains have been added to the vaccine for decades. Current composition of the vaccine has been used since 1985, and contains four strains: 1772/57 (year of isolation, 1957), 2047/57 (1957), 23/81 (1981) and 8/84 (1984). Because antigenic divergence has been found between B. pertussis vaccine strains and clinical isolates in many European countries, we wanted to analyse and compare these vaccine strains.
Methods: The analysis included serotyping of fimbriae (Fim) by slide agglutination, genotyping of pertussis toxin S1 subunit (ptxA) and pertactin (prn) by sequencing and LightCycler PCR, and DNA fingerprinting by pulsed-field gel electrophoresis (PFGE). The band patterns obtained by PFGE were analysed using the computer software BioNumerics. Different profiles were defined by band differences in the DNA band patterns and compared with those from international reference strains, Finnish vaccine strains (1772 and 18530) and clinical isolates.
Results: All three serotypes Fim2 (8/84), Fim3 (23/81) and Fim2,3 (1772/57 and 2047/57) were confirmed among the four vaccine strains. The strains 1772/57 and 2047/57 represented ptxA2, and strains 23/81 and 8/84 were ptxA1.The prn2 occurred only in strain 8/84, and the other three demonstrated prn1. Four different PFGE profiles were found: BpSR23 (1772/57), BpFINR1 (2047/57), BpFINR9 (23/81) and BpSR46 (8/84). Strain 1772/57 had the same PFGE profile as the Finnish vaccine strain 1772. Strain 2047/57 had the profile predominant among the Finnish strains isolated in the 1950s-1960s. The profile of 23/81 was prevalent in Finland in the 1970s, and the profile of strain 8/84 was found among the Finnish isolates from the 1970s and early 1990s. The Finnish vaccine strains represented ptxA2 or ptxA3/prn1, whereas the current circulating strains represented ptxA1/prn2.
Conclusions: The Serbian vaccine strains showed differences in ptxA and prn as well as in the PFGE profiles. The PFGE profiles of the vaccine strains were similar to the Finnish isolates from the same decades and different from the current Finnish circulating strains.

P1333 Evaluation of a new meningitis vaccine in healthy African population: hope on the horizon

B.J. Okoko on behalf of the MVP Trial Group

Introduction: Recurrent severe epidemics of meningococcal disease strike the meningitis belt extending from Senegal to Ethiopia. Annual incidences can reach 1,000/100,000 vs. 1/100,000 in developed countries. Group A meningococcus has remained unique in its ability to cause large epidemics. A vaccine that induces long-lasting protection and herd immunity is urgently needed. The Meningitis Vaccine Project (MVP) was funded in 2001 as a partnership between WHO and PATH to accelerate the development and introduction of affordable meningococcal conjugate vaccines. MVP's goal is to eliminate meningococcal epidemics in sub-Saharan Africa. A new MenA conjugate vaccine, manufactured by Serum Institute of India Ltd Pune – India, PsA-TT was safe and immunogenic with durable immunity when tested in a Phase I study in Indian adults. The vaccine is currently being tested in two phase II/III clinical studies where safety and immunogenicity are being studied among African population 1–29 years of age.
Method: Two observer-blind, randomised, controlled studies to assess safety, immunogenicity, induction of immune memory, antibody persistence of PsA-TT and pharyngeal carriage of Meningococcus in African toddlers aged 1–29 years are underway in Gambia, Mali and Senegal. After parental informed consent, each participant received a single intramuscular injection of study vaccine (PsA-TT), reference vaccine (ACYW135), and control vaccine (*Haemophilus influenzae* b) in the MVP 002 trial. Blood samples were obtained prior to immunisation and 4 weeks later for serum bactericidal antibody (SBA) activity and anti-polysaccharide group A (anti-PsA) IgG levels. Participants were followed for safety evaluation for 4 weeks.
Results: Preliminary result is available for the 601 toddlers aged 12–23 months from Gambia and Mali. PsA-TT was safe; rSBA GMT at baseline were 14, 16 and 13 for PsA-TT, PsACWY and Hib-TT; and rose to 6234, 365 and 61 with four-fold rises observed in 96%, 64% and 36% of recipients respectively, at week 4. 900 children and young adults aged 2–29 years have been enrolled in Gambia, Mali and Senegal for safety evaluation, antibody persistence and pharyngeal carriage. There is no safety issue to date and the study is on-going. The MVP 002 booster results soon to be available will be presented.
Conclusion: These unambiguous data are encouraging as MVP and partners continue their efforts to develop an affordable Men A conjugate vaccine for Sub-Saharan Africa.

P1334 The serotype-specific efficacy and immunogenicity of a 9-valent pneumococcal conjugate vaccine determined during an efficacy trial in The Gambia, West Africa

J. Okoko, M. Saaka, R.C. Kohberger, E. Biney, G. Enwere, A. Zaman, D. Goldblatt, F. Cutts, B.M. Greenwood, R.A. Adegbola (Banjul, GM; Greenwich, US; London, UK)

Background: A large randomised, double-blind, placebo-controlled vaccine trial in The Gambia showed that a 9-valent pneumococcal conjugate vaccine (PCV-9) had high efficacy against radiological pneumonia and invasive pneumococcal disease of vaccine serotype and reduced substantially hospital admissions and child mortality. Here, we report post vaccination pneumococcal antibody concentration in a nested subsample of infants who participated in this trial.

Methods: A single 2–4 ml venous blood specimen was collected from 213 4–6 weeks Gambian children after the third dose of vaccine or placebo and tested by ELISA for type-specific IgG antibodies to pneumococcal serotype 1, 4, 5, 6B 9V 14 18C, 19F and 23F polysaccharides. And from the main trial, we performed per-protocol and intention-to-treat analyses to assess the serotype specific vaccine efficacy.

Results: Geometric Mean Concentrations (GMCs) were significantly higher for each serotype in children receiving three doses of PCV-9 than those in placebo group. Among PCV-9 recipients, GMCs ranged between 2.61 and 11.09 μg/ml with the highest being against serotype 14 and the lowest against 9V. Point estimates of the proportion of infants with post vaccination antibody concentrations $\geqslant$0.15 μg/ml, $\geqslant$0.35 or $\geqslant$1.0 μg/ml ranged from 97.9% – 100%, 92.9% – 100% and 83.9% – 95.8%, respectively, for individual polysaccharides. In contrast, only 9.6% – 39.0%, 7.2% – 20.9% and 1.1% – 10.1% of infants in the placebo group attained these antibody concentrations. The estimated overall protective level for all the 9 serotypes, based on the vaccine efficacy against vaccine type specific invasive pneumococcal disease of 77% (95% CI: 51, 90) observed in the whole trial, was 2.3 μg/ml(95% CI: 1.0, 5.0).

Conclusion: The 9-valent pneumococcal conjugate vaccine studied was immunogenic in a Gambian population where it was also found to be efficacious

P1335 Serum bactericidal antibody response to polysaccharide meningococcal vaccination in common variable immunodeficiency and its clinical implications

N. Rezaei, A. Aghamohammadi, S. Siadat, M. Moin, Z. Pourpak, M. Nejati, H. Ahmadi, S. Kamali, D. Norouzian, B. Tabaraiee, R. Read (Sheffield, UK; Tehran, IR)

Objectives: Common variable immunodeficiency (CVID) is a heterogeneous group of disorders, characterised by hypogammaglobulinaemia and recurrent bacterial infections. Some patients with CVID make a successful immune response to polysaccharide vaccine. In this study, we examined the clinical features of those patients with CVID who respond poorly to polysaccharide meningococcal vaccine.

Methods: Twenty-five cases with CVID (18 male and 7 female) and 25 healthy volunteers received meningococcal polysaccharide vaccine A + C. Serum bactericidal antibody (SBA) titres were measured at baseline and after 3 weeks. Response was correlated with clinical and immunological manifestations of CVID.

Results: The serum bactericidal geometric mean titres (GMT) post-vaccination in the CVID patient group was 7.36, which was much lower than the control group (12.13). Twenty-four of 25 controls (96%) had a protective SBA titre of $\geqslant$8 post vaccination, whereas only 16 of 25 CVID patients (64%) had a protective titre (P-value=0.013). Amongst the cases of CVID who were non-responders, there was a significantly increased rate of bronchiectasis (P =0.008), splenomegaly (P =0.016), and autoimmunity (P =0.034) in comparison with patients who had protective SBA titres. A reversed CD4/CD8 ratio was more common in the non-responder group of patients.

Conclusion: The responder patients may have a good prognosis, while non-responder patients may have undefined immune abnormalities leading to several complications, such as bronchiectasis, opportunistic infections, splenomegaly, and autoimmunity. Therefore, vaccination response may provide a novel functional sub-classification of CVID patients, enabling accurate prognostic evaluation to identify high-risk patients at the time of diagnosis.

P1336 Changes in the epidemiology of invasive pneumococcal disease in adults after introduction of PCV7 in children, Barcelona, Spain

C. Ardanuy, F. Tubau, L. Calatayud, M. Dominguez, D. Rolo, I. Grau, R. Pallares, R. Martín, J. Liñares (L'Hospitalet de Llobregat, ES)

Objectives: The PCV7 pneumococcal vaccine for children was licensed in June 2001 in Spain. Currently, the estimated uptake of PCV7 is about 40–50%. The aims of this study were to analyse the distributions of serotypes and genotypes and the changes in the incidence of invasive pneumococcal disease (IPD) in adult patients in our geographical area in the pre- and post-vaccine periods.

Methods: A total of 1200 cases of IPD collected in 3 hospitals in our area in Barcelona were enrolled in order to estimate the incidence of IPD. Only pneumococci isolated from adult patients admitted to Hospital Universitari de Bellvitge (n= 876) were available for serotyping and molecular typing (PFGE and MLST). Antibiotic susceptibility was performed by microdilution.

Results: The most frequent serotypes throughout 1997–2006 period were 3 (11.3%), 14 (8.3%), 1 (7.8%), 9V (6.2%), 19F (4.9%), 4 (4.8%), 5 (4.4%), 19A (4.4%), and 23F (4.0%), and the dominant genotypes were Spain9V-3 (11.4%), ST260-serotype 3 (6.7%), Sweden1–28 (5.6%), and Spain23F-1 (4.5%). When 1997–2001 and 2002–2006 periods were compared, the following changes were observed (all $p < 0.05$): a) An increase in the incidence of IPD (cases/100.000 persons) from 12.9 to 16.4 for all adults and from 7.9 to 10.6 for adults 15–64 years old; b) The incidence of IPD caused by non-vaccine serotypes rose from 7.8 to 11.6 for all adults, from 5.0 to 7.5 for persons 15–64 years old and from 22.9 to 32.0 for persons >64 years old; c) The incidence of IPD caused by vaccine serotypes fell 22% (95% CI, −41 to 3) for persons >64 years old; d) A decrease of vaccine-related clones (Spain23F-1, Spain6B-2, Spain14–5, ST247-serotype 4 and ST88-serotype 19F); e) An increase of non-vaccine serotypes 7F, 24 and 35B and non-vaccine clones (Sweden1–28, Denmark14–32, Netherlands7F-39, ST989-serotype 12, ST433-serotype 22 and ST558-serotype 35B); f) A decrease of penicillin-, tetracycline-, chloramphenicol- and cotrimoxazol-resistance.

Conclusion: An increase of incidence of IPD was observed in adult patients in our area in 2002–2006 period, and it was associated with an increase of the incidence of IPD caused by non-vaccine serotypes. The incidence of IPD caused by vaccine-serotypes remained stable among persons 15 to 64 years of age, whereas it felt for adults over 64. A significant decrease in antibiotic resistance rates related to decrease of multiresistant clones was observed in our geographical area.

P1337 The evaluation of three pro-inflammatory cytokines

A. Sharifat Salmani, S.D. Siadat, H. Ahmadi, D. Norouzian, B. Tabaraiee, M. Alimagham, S. Farahmand, M. Kheirandish, M. Zangeneh, Q. Behzadiannejad (Tehran, IR)

Objective: Smooth Lipopolysaccharide (S-LPS) is the most antigenic structure expressed on the surface of *Brucella* smooth strains which promotes the innate and adaptive immune responses. LPS-induced innate immune responses are involved in the proinflammatory reactions and the release of proinflammatory cytokines, such as TNF-α, IL-1Beta and IL-6. The controlled increase of proinflammatory responses would be achieved by the application of adjuvants and studied as a method to induce the innate immune responses against the LPS of *Brucella*. Outer membrane vesicle of *Neisseria meningitidis* is one of the newly studied adjuvants with microbial origin and Several studies

carried-out about the probability of *Neisseria meningitidis* OMV application as an adjuvant. We have analysed the induction of three proinflammatory cytokines(TNF-α, IL-1β and IL-6)in immunised animal models with extracted S-LPS of *B. abortus* S99 complexed with OMV of N.meningitids, as an adjuvant.
Methods: The S-LPS of *Brucella* was extracted by hot phenol-water method. Then extracted S-LPS injected to mice in two different patterns, 1: *B. abortus* S-LPS 2: *B. abortus* S-LPS-*N. meningitidis* OMV (OMV as a probable potent adjuvant) noncovalent complex. After injections, animals were bled in 7, 14, 21 and 28'th and Finally sera analysed to detect the level of TNF-alfa, IL-1β and IL-6 by ELISA method.
Results: IL-6 was the first detected cytokine one week after the first injection. Peak amount of IL-6 detected two weeks after the first injection and there was not a significant difference between IL-6 amounts in LPS and LPS-OMV immunised groups. TNF-α and IL-1β were not detected in serum of S-LPS-immunised animals after the injections but interestingly both of these two cytokines were detected in the serum of animal inoculated with the S-LPS-OMV complex. The peak amounts of IL-1β and TNF-α were detected three weeks after the injection.
Conclusion: OMV can efficiently induce the production of IL-1β and TNF-α in the studied animal models. Since IL-1β and TNF-alfa are cytokines with innate cellular immunity sources and innate immunity is an important primary barrier against *Brucella* infection, we can conclude that OMV could be applied as an effective adjuvant in the candidate vaccines to elicit a more potent cell mediated innate immune response, in parallel with the augment of specific humoral and cellular responses against *Brucella* LPS.

P1338 Evaluation of pro/anti inflammatory responses after rectal administration of *Mycobacterium bovis* BCG

H. Movassagh, S. Rafati, B. Yazdanpanah, F. Khadem, H. Khanahmad Shahreza, M. Pooya, T. Sohrabi, M. Rostami Baroei, R. Moukhah, M. Abolhassani (Tehran, IR)

Objectives: Rectal administration of BCG induces a protective immune response against tuberculosis in animal models interestingly without any inflammatory complications. To understand the lack of inflammation we evaluated expression pattern of pro/anti inflammatory agents in the colorectal epithelial cell lines and fresh prepared epithelial cells (ECs) in presence or absence of intraepithelial lymphocytes (IELs). The regulatory mechanism of these expression profiles was studied by comparison of NFkB and PPARg activity.
Methods: IL-8 secretion was measured in Caco-2, HT-29 and SW-480 cell lines challenged with BCG by ELISA method. NFkB activity of the cell lines was assayed by DNA-based ELISA. IL-8 and IL-4 secretion was measured in guinea pig and macaque after rectal immunisation of BCG and also in their corresponding ECs and ECs+IELs. PPARg activity of macaque EC and ECs+IELs was measured by DNA-based ELISA. mRNA expression profile of some cytokines and chemokines in mice vaccinated with rectal BCG was determined using RNase protection assay (RPA).
Results: In response to BCG, IL-8 increased in a time dependent manner. This increase was corresponded by increase in NFkB activity. Guinea pig and macaque ECs showed the same behaviour by remarkable increases in IL-8 level. However ECs+IELs challenged with BCG didn't increase IL-8. We demonstrated a dramatic increase of 4 and 7 fold in IL-4 levels in ECs+IELs. Also PPARg activity was doubled during 24 hours in ECs. Two and seven days after BCG administration in mice, RPA was run on RNA from total colon, ECs and EC+IELs. The expression of pro-inflammatory cytokines IL-6, IL-18, IL-12p40, IL-1b, IFNg and MIF was increased in ECs lonely, whereas this effect was followed only by 2 days in ECs+IELs or in total colon. But in 7 days after BCG stimulation, the levels of these inflammatory agents were normalised. The same pattern was observed for the chemokines MIP-2 and MCP-1 while RANTES and IP-10 increased remarkably upto day seven. Anti-inflammatory cytokine IL-10, undetectable in ECs, was highly increased in ECs+IELs and also in total colon.
Conclusion: Rectal delivery of BCG induces an early balanced inflammatory process orchestrated by pro-inflammatory agents and Th2 mediated modulations that are controlled by a late IL-10 response. This balance is mainly due to IELs interactions which stable homeostasis at the colorectal mucosal surfaces.

P1339 Recombinant bacterial ghosts as a new vaccination approach against *Helicobacter pylori* infection

Y. Talebkhan, M. Esmaeili, M. Bababeik, M. Mohammadi (Tehran, IR)

Objectives: Genetic inactivation of Gram-negative pathogenic bacteria through controlled expression of cloned lysis gene E originated from bacteriophage PhiX174 has offered new insights in developing non-living vaccines specially those meant for oral administeration. Bacterial ghosts are empty cell envelopes derived mostly from Gram-negative bacteria by controlled expression of cloned lysis gene E. The induced trans-membrane tunnels in the cell wall expels the cytoplasmic contents while maintaining the antigenic properties of a living intact cell.
The high prevalence of *Helicobacter pylori* (Hp) infection is a major health problem worldwide especially in developing countries such as Iran, thus demanding the development of efficient vaccine strategies to prevent infection in early childhood. Since bacterial ghosts can mimic bacteria in structural properties, Hp ghosts expressing immunogenic proteins maybe a suitable approach.
Methods: omp18 gene was amplified from a local Hp strain through gene-specific PCR with designed primers according to published sequences in the GenBank and cloned under a chemical inducible promoter into Hp/*E. coli* shuttle vector.
The second antibiotic selection marker was also cloned in the above recombinant vector. Protein expression was induced in *E. coli* by IPTG and confirmed via immuno blotting using true Hp positive and negative sera. *E. coli* cells were co-transformed with lysis and expression vectors. Developing bacterial ghosts was performed by elevating the temperature to 42C after primary IPTG induction of Omp18 expression.
Results: The nucleotide homogeneity of Iranian omp18 gene was up to 95%. Kanamycin resistance gene (Kanar) was cloned in the recombinant vector as the 2nd antibiotic marker. The specific 25kDa Omp18 protein was observed on 15% SDS-PAGE and its immunogenicity was confirmed via immunoblotting. Co-expression of omp18 and lysis genes was performed and generation of bacterial ghosts expressing Hp Omp18 was confirmed by blotting.
Conclusion: The expression of recombinant Omp18 protein and bacterial ghost production in *E. coli* system has been confirmed. The expression of two cloned genes (Omp18 and Lysis E protein) is being optimised and the constructed ghosts are going to be examined in a helicobacter animal model employing C57BL/6 mice.

P1340 Sources of infection of pertussis in infants too young to be vaccinated

S.C. de Greeff, A. Westerhof, M. Peeters, H. Verbakel, C.J. Heuvelman, F.R. Mooi, H.E. de Melker (Bilthoven, Tilburg, NL)

Objectives: Despite high vaccine coverage (96%), pertussis is endemic in The Netherlands.
Several changes in the vaccination schedule have been implemented: introduction of an acellular preschool booster in 2001 and replacement of a whole-cell vaccine by an acellular vaccine since 2005. Still, infants too young to be vaccinated are at greatest risk for severe pertussis. To investigate the optimal vaccine strategy to protect infants, we determined their source of infection.
Methods: From February 2006 until December 2008, all paediatricians, microbiologists and public health personnel are asked to notify any hospitalised child younger than 6 months of age with pertussis. From household members of the hospitalised infant, a nasopharyngeal swab and buccal cells will be obtained for PCR or culture to identify B. pertussis or B. parapertussis. Furthermore, IgG-PT and IgA titres are assessed and clinical symptoms and vaccination history are determined.

Results: In the first 18 months of study, 109 index patients and 411 household members were enrolled. Of the latter, 200 (49%) had laboratory confirmed B. pertussis infection and 4 (1%) B. parapertussis infection. Of the infected household members, 88% were vaccinated. For 73% of these typical cough symptoms were reported, with a median duration of 30 days. Three children and one adult were hospitalised. Preliminary results indicate that 25% of the mothers, 10% of the fathers and 21% of the siblings in the study had introduced pertussis in the household and thus most likely transmitted the infection to the infant.
Conclusions: Preliminary results demonstrate that siblings and mothers are most often the source of infection of pertussis in infancy in the Netherlands. Vaccination of household members of infants may eliminate a substantial part of pertussis disease burden in infants. Besides, symptomatic pertussis infection occurs frequently in adults. Dynamic modelling will be used to determine what vaccination strategy is the most (cost-)effective way to reduce disease burden due to pertussis, with prevention of pertussis among infants as main focus.

Diagnosis, pathogenesis and in vitro studies in fungal infections

P1341 Diagnosing fungaemia faster

J.D. Knudsen, M.C. Arendrup (Hvidovre, DK)

Objective: Rapid initiation of appropriate antifungal treatment is associated with a reduction in mortality. Unfortunately species identification and susceptibility testing is time consuming. Recently, a commercial susceptibility testing card to the VITEK system was developed, and we decided to evaluate this in a routine laboratory in comparison with the EUCAST reference method.
Methods: A strain collection of 20 yeast isolates from blood cultures (8 *C. albicans*, 6 *C. glabrata*, 2 *C. tropicalis*, 2 *C. parapsilosis*, 1 *C. krusei* and 1 *Cryptococcus neoformans*), were tested by VITEK® by the AST-YS01 card and the results were correlated to the MICs obtained by the EUCAST method performed at the reference laboratory. The VITEK resistance card includes amphotericin B, fluconazole, voriconazole and flucytosine. The EUCAST testing was performed as part of a surveillance scheme and included amphotericin B, fluconazole, voriconazole, itraconazole, posaconazole and caspofungin. Agreement was defined as identical classification in S, I/SDD/ and R.
Results: There were 100% agreement for amphotericin B susceptibilities, and all the strain's MICs were $\leqslant 1$ μg/mL.
For 17:20 isolates the interpretations were in agreement for the azoles if S $\leqslant 2$ μg/mL for fluconazole, S $\leqslant 1$ μg/mL for voriconazole. Two strains showed minor disagreements for fluconazole, with MICs of 0.5 and 2 μg/mL by the EUCAST, and both 4 μg/mL by the VITEK method. One *C. tropicalis* showed high level resistance towards fluconazole and voriconazole by the EUCAST method, MICs >16 and >4 μg/mL, but by VITEK the MIC's were <1 and <0.12 μg/mL, respectively. This strain will be further examined. Flucytosine susceptibilities were tested by VITEK, and only the *C. krusei* were found resistant, MIC=16 μg/mL. The VITEK results were ready after median 18 h (range 13–21).
Conclusion: The susceptibility profiles for the antifungals included in the card were reliably done overnight from colonies on agar plates. Including an resistance card when using identifications cards by VITEK, may be less time consuming, and is economical attractive compared to our routine methods. There is two disadvantages so far, no echinocandins are yet included in the card, and there is not yet any easy procedure for using samples directly from the blood culture bottles.

P1342 Evaluation of two chromogenic *Candida* agars: need for additional training to optimise results

S. Cooreman, I. Mermans, H. Goossens, M. Ieven (Edegem, BE)

Objectives: To evaluate two chromogenic agars for the identification of clinically relevant yeasts: OCCA (Oxoid) and Candiselect4 (Biorad). Candiselect4 allows species identification of *Candida albicans*, *Candida glabrata*, *Candida krusei* and *Candida tropicalis*. OCCA agar identifies the same species, as well as *Candida dubliniensis*, *Candida parapsilosis*, *Candida kefyr* and *Candida lusitaniae*, but recommends to classify isolates into 4 clinical relevant groups (*C. glabrata* + *C. parapsilosis*; *C. albicans* + C.dubliensis; *C. krusei*; *C. tropicalis*). The second objective was to evaluate if the % correct identification (PCI) could be improved by additional training of laboratory technicians.
