

## SOLUTIONS TO TUTORIAL EXAMPLES

### CHAPTER 4

#### Question 1

Remember that, on earth, a force of 10 Newtons is equivalent to a mass of 1 kg.

- a) A mass of 70 kg is equivalent to a weight of 700 N, or 0.7 kN.
- b) A mass of 95 kg is equivalent to a weight of 950 N, or 0.95 kN.

On the moon, the weight of each of these people would be one-sixth of their weight on earth.

- a) The weight of a 70 kg mass on the moon =  $70 \text{ kg} \times 10/6 = 117 \text{ N} = 0.117 \text{ kN}$ .
- b) The weight of a 95 kg mass on the moon =  $95 \text{ kg} \times 10/6 = 158 \text{ N} = 0.158 \text{ kN}$ .

#### Question 2

Volume of brick:

In millimetre (mm) units =  $(215 \text{ mm} \times 102.5 \text{ mm} \times 65 \text{ mm}) = 1\,432\,438 \text{ mm}^3$ .

In metre (m) units =  $(0.215 \text{ m} \times 0.1025 \text{ m} \times 0.065 \text{ m}) = 0.0014 \text{ m}^3$ .

Density = mass/volume, so mass = density  $\times$  volume.

Mass =  $1800 \text{ kg/m}^3 \times 0.0014 \text{ m}^3 = 2.52 \text{ kg}$

Weight of brick =  $2.52 \text{ kg} \times 10 = 25.2 \text{ N} = 0.025 \text{ kN}$ .

#### Question 3

Weight of concrete beam = volume  $\times$  unit weight

$$\begin{aligned} &= (9 \text{ m} \times 0.2 \text{ m} \times 0.35 \text{ m}) \times 24 \text{ kN/m}^3 \\ &= 15.1 \text{ kN} \end{aligned}$$

#### Question 4

Assume:

Average weight of each student = 0.8 kN  
Average weight of each desk = 0.2 kN  
Average weight of each chair = 0.1 kN  
TOTAL = 1.1 kN

Total weight of 60 students + furniture =  $60 \times 1.1 = 66$  kN  
Area of classroom =  $10 \text{ m} \times 12 \text{ m} = 120 \text{ m}^2$   
Actual load / $\text{m}^2 = 66 \text{ kN}/120 \text{ m}^2 = 0.55 \text{ kN}/\text{m}^2$

This is much less than  $3.0 \text{ kN}/\text{m}^2$ . OK.

#### Question 5

Average depth of swimming pool = 1.5 metres  
Volume of water in pool =  $25 \text{ m} \times 10 \text{ m} \times 1.5 \text{ m} = 375 \text{ m}^3$   
Unit weight of water =  $10 \text{ kN}/\text{m}^3 = 1 \text{ tonne}/\text{m}^3$   
Weight of water in pool = 375 tonnes.  
This is equivalent to the weight of 375 small cars.

Advice to architect/client: the proposed swimming pool will increase the load on the supporting walls and columns by a huge amount. They will need to be appraised and possibly supplemented or rebuilt to accommodate this increased load.

#### Question 6

1 hectare =  $10\,000 \text{ m}^2$ , and 1 hectare = 2.47 acres  
Area of site =  $(300 \text{ m} \times 250 \text{ m}) = 75\,000 \text{ m}^2 = 7.5 \text{ hectares} = (7.5 \times 2.47) \text{ acres} = 18.5 \text{ acres}$ .

#### Question 7

##### **Calculations: £1 coin**

The mass of a £1 coin is 9.7 grams.  
Therefore the **mass** of a million £1 coins is  $9.7 \times 10^6$  grams = 9700 kg.  
Therefore the **weight** of a million £1 coins is  $(9700 \times 10) = 97\,000 \text{ N} = 97 \text{ kN}$ .  
(This is because  $10 \text{ N}$  (weight) is equivalent to  $1 \text{ kg}$  (mass).)

A £1 coin has a diameter of 22 mm and a thickness of 3 mm.

Assuming a stacking configuration as illustrated above, each pound coin occupies a volume of  $(22 \text{ mm} \times 22 \text{ mm} \times 3 \text{ mm}) = 1452 \text{ mm}^3$ .

Therefore the **volume** of a million pound coins is  $1452 \times 10^6 \text{ mm}^3 = 1.452 \text{ m}^3$ . (because  $1 \text{ m}^3 = 10^9 \text{ mm}^3$ ).

Density = mass/volume =  $97 \text{ kN}/1.452 \text{ m}^3 = 66.8 \text{ kN/m}^3$  (this compares well with the published unit weight of steel =  $78.5 \text{ kN/m}^3$ ).

### **Calculations: £2 coin**

A £2 coin is both heavier and larger than a £1 coin, but only 500 000 will be required (since  $£2 \times 500\,000 = £1 \text{ million}$ ).

The mass of a £2 coin is 11.9 grams.

Therefore the **mass** of 500 000 £2 coins is  $11.9 \times 500\,000 = 5.95 \times 10^6 \text{ grams} = 5950 \text{ kg}$ .

Therefore the **weight** of 500 000 £2 coins is  $59\,500 \text{ N} = 59.5 \text{ kN}$  (again, because 10 N (weight) is equivalent to 1 kg (mass)).

A £2 coin has a diameter of 29 mm and a thickness of 2.5 mm.

Assuming the same stacking configuration as above, each £2 coin occupies a volume of  $(29 \text{ mm} \times 29 \text{ mm} \times 2.5 \text{ mm}) = 2102.5 \text{ mm}^3$ .

Therefore the **volume** of 500 000 £2 coins is  $2102.5 \times 500\,000 = 1.051 \times 10^9 \text{ mm}^3 = 1.051 \text{ m}^3$ .

Density = mass/volume =  $59.5 \text{ kN}/1.051 \text{ m}^3 = 56.6 \text{ kN/m}^3$ .

## ***Discussion***

The volumes of £1 worth of £1 coins and £2 coins are  $1.452 \text{ m}^3$  and  $1.051 \text{ m}^3$ , respectively. Either of these would fit in the back of a light van. However, the main problem is the weight. The weight of a million £1 coins is nearly 10 tonnes (since  $10 \text{ kN} = 1 \text{ tonne}$ ) so a heavy duty vehicle would be required to transport this load. The £2 coin option weighs just under 6 tonnes – considerably lighter but still requiring a heavy duty vehicle to transport it.

On the storage question, the live load assumed in domestic construction is  $1.5 \text{ kN/m}^2$  (British Standard BS 6399). Therefore, the floor area required for the £1 coin option =  $97 \text{ kN} / 1.5 \text{ kN/m}^2 = 64.6 \text{ m}^2$ , and the floor area required for the £2 coin option =  $59.5 \text{ kN} / 1.5 \text{ kN/m}^2 = 39.7 \text{ m}^2$ . So, even the lighter £2 coin option would require the load to be spread over a floor area of about  $40 \text{ m}^2$  or 430 square feet, which is the total floor area of a typical one-bedroom apartment.

It can be seen that the weight of the 'haul' poses problems for both transport and storage. The most realistic option would be to engage the services of a security company to transport the money to the nearest bank.
